The expression ««a» is synonymous with «b»» suggests a relation between «a» and «b», but nothing has been said about this relation, which has a bearing on the question of reflexivity. Let us, however, consider a pair of interpretative sentences of the skeletal form «--- has the meaning . . .», such that they can be brought into the form:

««a» has the meaning N_1 .»

««b» has the meaning N_2 .»

II.6. Reflexivity, Symmetry, and Transitivity of Some Relations

Such pairs of interpretative sentences may be connected with synonymy sentences if it is said whether 'a' and 'b' are identical or different. If identical, the pair can be rewritten thus: «*a*» has the meaning N_1 and «*b*» has the meaning N_2 , and N_1 and N_2 are identical».

It is tempting to define concepts of synonymy by means of such complex sentences involving reference to identical meanings. It is not in this work done in just that way, but let us consider for the moment what would follow if such were carried out. Accordingly, we decide: «*x* is synonymous with *y*» shall in this section mean the same as «*x* expresses the meaning N_1 and *y* expresses the meaning N_2 , and N_1 and N_2 are identical».

For *x* and *y*, only a pair of expressions or instances of expressions may occur, either a pair of designations or a pair of declarative sentences. This and other conventions concerning the symbols $\text{Syn}(\text{---}, \text{---})$, introduced in chapter I, shall be taken as valid also for this section.

For N_1 and N_2 , any pair of entities may occur, the members of which can be said to be identical or not to be identical. This means that we do not try to indicate how meanings can be described.

In convenient symbols:

$$(1) \text{Syn}(xy) =_d \text{Sign}(xN_1) \ \& \ \text{Sign}(yN_2) \ \& \ \text{Id}(N_1N_2)$$

Now the question of reflexivity may be attacked. By substituting *x* for *y* in (1), we get:

$$(2) \text{Syn}(xx) \sim \text{Sign}(xN_1) \ \& \ \text{Sign}(xN_2) \ \& \ \text{Id}(N_1N_2)$$

Whether $\text{Syn}(xx)$ holds good depends on whether one may write:

$$(3) (x). \text{Sign}(xN_1) \ \& \ \text{Sign}(xN_2) \supset \text{Id}(N_1N_2)$$

Until now, no conventions have been introduced concerning the symbol « $\text{Sign}(\text{---}, \text{---})$ » that can justify the assertion of (3). Let us make the following convention:

$$(4) \text{Sign}(aN_1) =_D (i)(j). \text{Sign}(aP_iS_jN_1)$$

II. BASIC TERMS CONTINUED

where the right-hand expression may be read «The expression «a» signifies N_1 for all persons in all situations».

From (4) follows:

$$(5) \text{Sign}(aN_1) \supset \neg(Ei)(Ej). \text{Sign}(aP_iS_jN_2) \ \& \ \neg \text{Id}(N_1N_2)$$

From (5) follows (3), and from (3) follows the left-hand side of (2). The conclusion may be thus formulated, that if the following conventions are accepted—a normative definition of «x is synonymous with y» as indicated by (1); and a normative definition of «x signifies N_1 » as indicated by (4)—then the relation of synonymity, «x is synonymous to y», is *reflexive*. In symbols, and somewhat reformulated:

(6) If

$$(i)(j)\text{Syn}(aP_iS_jbP_iS_j) =_d$$

$$(i)(j)\text{Sign}(aP_iS_jN_1) \ \& \ (i)(j). \text{Sign}(bP_iS_jN_2) \ \& \ \text{Id}(N_1N_2)$$

then

$$(i)(j)\text{Syn}(aP_iS_jaP_iS_j)$$

It is to be noted that from $(Ei)(Ej). \text{Sign}(aP_iS_jN_1)$ and $(Ei)(Ej). \text{Sign}(aP_iS_jN_2)$ it cannot be inferred that N_1 and N_2 are identical. The expression «a» may be ambiguous.

By use of the normative definition, (1), of 'synonymity', the symmetry of the synonymity relation is proved directly. Substituting x for y and y for x in (1), we get:

$$\text{Syn}(yx) \sim \text{Sign}(yN_1) \ \& \ \text{Sign}(xN_2) \ \& \ \text{Id}(N_1N_2)$$

N_1 and N_2 being identical, they can replace each other:

$$(7) \text{Syn}(yx) \sim \text{Sign}(yN_2) \ \& \ \text{Sign}(xN_1) \ \& \ \text{Id}(N_1N_2)$$

On the other hand, from (1) follows:

$$(8) \text{Syn}(xy) \supset \text{Sign}(xN_1) \ \& \ \text{Sign}(yN_2) \ \& \ \text{Id}(N_1N_2)$$

II.6. Reflexivity, Symmetry, and Transitivity of Some Relations

$$(9) \text{Syn}(xy) \supset \text{Sign}(yN_2) \& \text{Sign}(xN_1) \& \text{Id}(N_1N_2)$$

The right-hand side of (9) is the same as that of (7). Therefore:

$$(10) \text{Syn}(yx) \supset \text{Syn}(xy)$$

From (7) and (9) also, the stronger assertion of equivalence is proved:

$$(11) \text{Syn}(xy) \sim \text{Syn}(yx)$$

Conclusion: Synonymity as defined by (1) is symmetrical.

From (1) and (4) follow by proper substitutions:

$$(12) \text{Syn}(ab) \& \text{Syn}(bc) \sim$$

$$(i)(j). \text{Sign}(aP_iS_jN_1) \& (i)(j). \text{Sign}(bP_iS_jN_2) \& \text{Id}(N_1N_2) \\ \& (i)(j). \text{Sign}(bP_iS_jN_2) \& (i)(j). \text{Sign}(cP_iS_jN_3) \& \text{Id}(N_2N_3)$$

$$(13) \text{Syn}(ab) \& \text{Syn}(bc) \supset$$

$$(i)(j). \text{Sign}(aP_iS_jN_1) \& (i)(j). \text{Sign}(cP_iS_jN_3) \& \text{Id}(N_1N_3)$$

From (1), (4), and (13) follows:

$$(14) \text{Syn}(ab) \& \text{Syn}(bc) \supset \text{Syn}(ac)$$

Synonymity defined by (1) and (4) is a *transitive* relation.

It is again essential to note the qualification that (1) and (4) must be presumed. If we use the name «universal synonymity» for synonymity valid for any person and any situation, the conclusion may be reformulated: universal synonymity defined by (1) is transitive.

b. Heteronymity

A term «heteronymous» can in analogy with (1) be introduced as follows:

«x is heteronymous with y» shall within this section mean the same as «x expresses the meaning N_1 and y expresses the meaning N_2 , and N_1 and N_2 are different».

II. BASIC TERMS CONTINUED

The new property shall be considered defined for the same range of entities, designations, and declarative sentences.

In symbols:

$$(15) \text{Het}(xy) =_d \text{Sign}(xN_1) \& \text{Sign}(yN_2) \& \text{-Id}(N_1N_2)$$

Let us consider the possibility that y is identical with x . «Heteronymy of x with x » would according to (15) mean that x expresses two different meanings. If one can affirm about x two interpretative sentences « x means N_1 » and « x means N_2 », then there are two implied synonymy sentences such that « x means the same as « c » and x means the same as « d » and $\text{Het}(cd)$ ». In symbols: $\text{Syn}(xc) \& \text{Syn}(xd) \& \text{-Syn}(cd)$. Now, according to a convention of chapter 1, section 2, $\text{Syn}(ab)$ is an abbreviation for $(i)(j)\text{Syn}(a_i b_j)$, and one may from this deduce:

$$\text{Syn}(ab) \supset (\text{Syn}(ac) \& \text{Syn}(ad) \& \text{-Syn}(cd))$$

If, now, $\text{Het}(x,x)$ implies the right-hand-side parenthesis of this implication, it implies something that is by adopted conventions ruled out. We may therefore assert the *irreflexivity* of heteronymy. It is to be noted, however, that this conclusion only applies to the sentences that can be brought into the form $(i)(j)\text{Het}(ab)$. A more precise conclusion would therefore be: ‘universal heteronymy’ is an irreflexive relation.

By use of the introduced conventions it is easily seen that ‘heteronymy’ is symmetrical. Let us consider transitivity.

From (15) follows

$$\begin{aligned} \text{Het}(xy) \& \text{Het}(yz) \sim. \text{Sign}(xN_1) \& \text{Sign}(yN_2) \& \text{-Id}(N_1N_2) \\ \& \text{Sign}(yN_2) \& \text{Sign}(zN_3) \& \text{-Id}(N_2N_3) \end{aligned}$$

Now, from

$$\text{-Id}(N_1N_2) \& \text{-Id}(N_2N_3)$$

does not follow $\text{-Id}(N_1N_3)$. $\text{Id}(N_1N_3)$ is possible. Therefore:

$$(16) \text{Not: Het}(xy) \& \text{Het}(yz) \supset \text{Het}(xz)$$

The relation of heteronymity is not *transitive*. Neither can $\neg\text{Het}(xz)$ be proved. The relation is therefore *not intransitive* (by definition). Empirically, $\text{Het}(xz)$ and $\neg\text{Het}(xz)$ may occur with considerable frequency for all we know. There is, therefore, no reason to postulate empirical transitivity or empirical intransitivity.

c. Synonymic Alternatives

That an expression «a» is a synonymic alternative of «b» is defined normatively in terms of the existence of at least one case of synonymy between «a» and «b». If «b» is identical with «a», the assertion gets the form «There is at least one case of synonymy between a pair of occurrences of «a»». It is, however, possible that «a» never is used, or will be used, twice with the same meaning. The relation of synonymic alternative is *not reflexive* (by definition). Neither is it irreflexive (by definition). Mostly, there will be a pair of occurrences such that $\text{Synalt}(aa)$ holds good: the relation is *empirically reflexive*.

In symbols:

$$\begin{aligned} \text{Synalt}(ab) &\sim (Ex)(Ey). x\in a \ \& \ y\in b \ \& \ \text{Syn}(xy) \\ (17) \text{Synalt}(aa) &\sim (Ex)(Ey). x\in a \ \& \ y\in a \ \& \ \text{Syn}(xy) \end{aligned}$$

There does not exist by definition such a pair (x,y) that it satisfies the right-hand expression of (17).

The assertion that there exists at least one pair of synonymous instances of «a» and «b» may be written:

$$\begin{aligned} (18) \text{Syn}(a_1b_1) \vee \text{Syn}(a_1b_2) \vee \dots \vee \text{Syn}(a_1b_m) \\ \vee \text{Syn}(a_2b_1) \vee \text{Syn}(a_2b_2) \vee \dots \vee \text{Syn}(a_2b_m) \\ \vee \dots \\ \vee \text{Syn}(a_nb_1) \vee \text{Syn}(a_nb_2) \vee \dots \vee \text{Syn}(a_nb_m) \end{aligned}$$

Whereas $\text{Synalt}(ab)$ is equivalent to the above disjunction, $\text{Synalt}(ba)$ is equivalent to

$$(19) \text{Syn}(b_1a_1) \vee \dots \vee \text{Syn}(b_ma_n)$$

II. BASIC TERMS CONTINUED

The equivalence of (18) and (19) can be shown only by taking up the question of the symmetry of $\text{Syn}(a_i b_j)$. If the normative definition (1) is used, this symmetry holds good and one gets:

$$(20) \text{Synalt}(ab) \sim \text{Synalt}(ba)$$

The relation of synonymic alternative is *symmetrical*, provided synonymity relations are symmetrical.

Suppose it is established that

$$(21) \text{Synalt}(ab) \& \text{Synalt}(bc)$$

(21) is equivalent to

$$(22) \text{Syn}(a_1 b_1) \vee \dots \vee \text{Syn}(a_n b_m) \& \text{Syn}(b_1 c_1) \vee \dots \vee \text{Syn}(b_m c_p)$$

The transitivity of the synonymity relation of the kind $\text{Syn}(x_1 y_1)$ implies that if there is a pair of instances of a_i, b_j and b_j, c_k such that

$$\text{Syn}(a_i b_j) \& \text{Syn}(b_j c_k)$$

then $\text{Synalt}(ac)$ follows from $\text{Synalt}(ab) \& \text{Synalt}(bc)$.

There may, however, in (22) be no such case. The relation of synonymic alternative is therefore not *transitive*.

d. Preciseness

Substituting «a» for «b» in the normative definition of «preciseness», chapter 1, section 12, (1s), one gets:

$$\begin{aligned} (23) \text{Pr}(aa) \sim & \neg(\text{Ex}). \text{Synalt}(xa) \& \neg\text{Synalt}(xa) \\ & \& (\text{Ey}). \text{Synalt}(ya) \& \neg\text{Synalt}(ya) \\ & \& (\text{Ez}). \text{Synalt}(za) \end{aligned}$$

The right-hand side of this equivalence contains contradictions. The relation of preciseness is therefore *irreflexive*.

II.6. Reflexivity, Symmetry, and Transitivity of Some Relations

From the normative definition of $\text{Pr}(ab)$ follows:

$$\begin{aligned} \text{Pr}(ab) \ \& \ \text{Pr}(ba) \supset \neg(\text{Ex}). \text{Synalt}(xa) \ \& \ \neg\text{Synalt}(xb) \\ & \ \& \ (\text{Ex}). \text{Synalt}(xa) \ \& \ \neg\text{Synalt}(xb) \end{aligned}$$

The right-hand side involves a contradiction. The relation of preciseness is therefore *asymmetrical*. From the normative definition of $\text{Pr}(ab)$ follow:

$$\begin{aligned} (24) \ \text{Pr}(ab) \ \& \ \text{Pr}(bc) \supset \neg(\text{Ex}). \text{Synalt}(xa) \ \& \ \neg\text{Synalt}(xb) \\ & \ .\& \ .(\text{Ex}). \text{Synalt}(xb) \ \& \ \neg\text{Synalt}(xa) \\ & \ .\& \ .\neg(\text{Ex}). \text{Synalt}(xb) \ \& \ \neg\text{Synalt}(xc) \\ & \ .\& \ .(\text{Ex}). \text{Synalt}(xc) \ \& \ \neg\text{Synalt}(xb) \\ (25) \ \text{Pr}(ac) \supset \neg(\text{Ex}). \text{Synalt}(xa) \ \& \ \neg\text{Synalt}(xc) \\ & \ .\& \ .(\text{Ex}). \text{Synalt}(xc) \ \& \ \neg\text{Synalt}(xa) \end{aligned}$$

From (24) follows:

$$\begin{aligned} \text{Pr}(ab) \ \& \ \text{Pr}(bc) \supset (\text{Ex}). \text{Synalt}(xc) \ \& \ \neg\text{Synalt}(xb) \\ & \ .\& \ .(x). \neg\text{Synalt}(xb) \supset \neg\text{Synalt}(xa) \\ (26) \ \text{Pr}(ab) \ \& \ \text{Pr}(bc) \supset (\text{Ex}). \text{Synalt}(xc) \ \& \ \neg\text{Synalt}(xa) \end{aligned}$$

On the other hand,

$$\begin{aligned} \text{Pr}(ab) \ \& \ \text{Pr}(bc) \supset (x). \text{Synalt}(xa) \supset \text{Synalt}(xb) \\ & \ .\& \ .(x). \text{Synalt}(xb) \supset \text{Synalt}(xc) \end{aligned}$$

Therefore,

$$(27) \ \text{Pr}(ab) \ \& \ \text{Pr}(bc) \supset \neg(\text{Ex}). \text{Synalt}(xa) \ \& \ \neg\text{Synalt}(xc)$$

From the N-definition of $\text{Pr}(ab)$ follows the existence of synonymic alternatives of «a». Consequently, from (26) and (27) and the normative definition, follows:

II. BASIC TERMS CONTINUED

$$(28) \text{Pr}(ab) \& \text{Pr}(bc) \supset \text{Pr}(ac)$$

The relation of preciseness, $\text{Pr}(ab)$, is *transitive*.

In those cases in which $\text{Synalt}(aa)$ and $\text{Pr}(ab)$ hold good, one can deduce that «b» is a synonymic alternative of «a»: from the normative definition of $\text{Pr}(ab)$, it follows that all synonymic alternatives of «a» must also be synonymic alternatives of «b»; hence, if «a» is a synonymic alternative of «a», then «a» must be a synonymic alternative of «b». From the symmetry of $\text{Synalt}(ab)$ follows the conclusion:

$$(29) \text{Pr}(ab) \& \text{Synalt}(aa) \supset \text{Synalt}(ba)$$

From $\text{Pr}(ab)$ alone, $\text{Synalt}(ab)$ or $\text{Synalt}(ba)$ does not follow: expressions may, in theory, be comparable in preciseness without admitting each other as synonymic alternatives. The less precise may never be used synonymously with the more precise. In practice, such cases seem exceedingly rare or even nonexistent.

e. Interpretation

In the adopted terminology, $\text{Int}(T_i P_1 T_0 P_1)$ means the same as «For P_1 T_i is sometimes synonymous to T_0 , and there exists a T_j such that $\text{Het}(T_j P_1 T_i P_1)$ and T_j sometimes is synonymous to T_0 ». That is,

$$(30) \text{Int}(T_i P_1 T_0 P_1) \supset \text{Synalt}(T_i P_1 T_0 P_1) \& (E_j). \text{Het}(T_j P_1 T_i P_1) \\ \& \text{Synalt}(T_j P_1 T_0 P_1)$$

Substituting T_0 for T_i in (30) one obtains:

$$(31) \text{Int}(T_0 P_1 T_0 P_1) \supset \text{Synalt}(T_0 P_1 T_0 P_1)$$

As the synonymic alternative relation is, according to (17), not reflexive, the interpretation relation is therefore *not reflexive*.

The interpretation relation is *not symmetrical* because $\text{Int}(T_0 P_1 T_i P_1) \supset \text{Synalt}(T_0 P_1 T_i P_1)$, and this synonymic alternative relation cannot be deduced from $\text{Synalt}(T_i P_1 T_0 P_1)$ or the whole of the right side of (30).

$$(32) \text{Int}(T_i P_1 T_0 P_1) \& \text{Int}(T_j P_1 T_i P_1) \supset \text{Int}(T_j P_1 T_0 P_1) \\ \cdot \supset. \text{Int}(T_i P_1 T_0 P_1) \& \text{Int}(T_j P_1 T_i P_1) \supset \text{Synalt}(T_j P_1 T_0 P_1)$$

The Synalt relation being not transitive, the right-hand side of (32) is not valid. The interpretation relation is therefore *not transitive*.

All derivations of this section have the sole purpose of clarifying interrelations between the basic terms introduced in the foregoing. The exercise is entirely of a formal or «pure» character, and completely useless for the development of a descriptive, hypothetico-deductive system of semantics as long as the introduced terms are not connected with *procedures of systematic observation*. Experience shows, however, that the erection of a conceptual framework is, on the one hand, sufficiently important to be considered in detail and, on the other hand, so much less complicated than the satisfactory implementation of empirical research programs, that the exposition of a basic conceptual framework can conveniently be made before empirical considerations are taken up. It should be unnecessary to repeat that the framework was not elaborated before empirical procedures were used, but hand in hand with empirical research.

II.7. Incomparability and Transintentionality in Relation to Preciseness

a. Equality of Preciseness

Let «a» and «b» be two expressions.

- (1) ««a» and «b» are *equally precise*» will in this work mean the same as «There are no synonymic alternatives of «a» that are not also synonymic alternatives of «b», and no synonymic alternatives of «b» that are not also synonymic alternatives of «a», and «a» has at least one synonymic alternative».

In short, «a» and «b» are equally precise, if they admit of the same synonymic alternatives.

In symbols:

$$(1s) \text{Idpr}(ab) =_d - (Ex). \text{Synalt}(xa) \& -\text{Synalt}(xb)$$

II. BASIC TERMS CONTINUED

.&. (Ex). Synalt (xa)

.&. - (Ex). Synalt (xb) & -Synalt (xa)

It can easily be shown that the relation 'equally precise' is reflexive, symmetrical, and transitive.

If an expression «a» is more, equally, or less precise than another expression «b», the expressions will be said to be *comparable* in preciseness; if otherwise, *incomparable*.

Incomparability is realized if, but not only if, each expression admits of synonymic alternatives that the other does not admit—in other words, if they both have their own synonymic alternatives.

In symbols:

(Ex). Synalt(xa) & -Synalt(xb) .&. (Ex). Synalt (xb) & -Synalt (xa)

: \supset : Incompr. (ab)

For many reasonable criteria of synonymy, most expressions will be incomparable. Of more interest is the question of comparability within subclasses of occurrences: the question of whether «a» of subclass M_i is comparable in preciseness to «b» of subclass M_j .

An expression «a» may or may not be a synonymic alternative of itself (see section 6, page 109). That is, there may or may not exist cases of synonymy between instances of «a». As a general rule, there are such cases. To be comparable in preciseness, «a» and «b» must, according to the normative definitions, each admit of a synonymic alternative. This necessary condition is as a general rule satisfied, because «a» generally has «a» as a synonymic alternative, and «b» has «b».

To be comparable in preciseness, expressions need not be synonymic alternatives of each other, but if they are comparable, they will have at least one synonymic alternative in common.

b. Preciseness and Transintentionality

Suppose that T_1 is more precise than T_0 for a person P, and that he sometimes uses T_1 , sometimes T_0 . The relation is presumed to be found by investigating the use occurrences of T_0 and of T_1 .

Suppose, further, that P's definiteness of intention is on the whole greater when he uses T_1 than when he uses T_0 . This is likely to happen: more precise formulations are likely to be the result of more careful evaluation of terms and more careful introspection of intentions.

Suppose, lastly, that it is found that an expression T_2 is more precise than T_1 , taking use occurrences of T_1 by P as subject matter of this preciseness relation. It is of importance to note that the marginal references are assumed to be different in the two cases of preciseness relation, and that therefore the transitivity theorem of section 6 does not cover them. In other words, from T_1 being more precise than T_0 under certain conditions, and T_2 being more precise than T_1 under other conditions, it does not follow that T_2 is more precise than T_0 .

It may happen, that in relation to use occurrences of T_0 by P, all those interpretations of T_2 that were considered in order to arrive at the conclusion that T_2 is more precise than T_1 , are transintentional in relation to use occurrences of T_0 .

Occurrences of T_0 may for P be accompanied by such a low definiteness of intention that one cannot say positively whether T_0 *for P sending* T_0 admits of all interpretations of T_2 . The possibility of such interpretations is not even implicitly considered by P. Consequently, one cannot use the normative definition of «more precise than». T_2 and T_0 are, in relation to use occurrences of T_0 by P, *incomparable* in preciseness, whereas T_2 is more precise than T_1 in relation to use occurrences of T_1 by P.

This kind of incomparability, here attached to use occurrences, may equally well hold good in relation to interpretative processes during reading and listening.

Roughly speaking, superficiality may function to guard against misinterpretation: the wording of a formulation T_0 may be such that it does not seem to pretend to be the product of close, concentrated attention and deep reflection. Moreover, the sender may speak without having fairly definite things to say. The receiver understands the situation and does not concentrate his search for definite meanings. There is in such cases little room for misinterpretation because there is very little to misinterpret. The process of interpretation, in cognitive senses, is functioning only very feebly, but, maybe, highly efficiently in the situations under consideration.

If the sender of T_0 , in order to avoid ambiguities, reformulates his

II. BASIC TERMS CONTINUED

words, and uses T_2 instead, the fairly strong precization is likely to contain complicated expressions and is apt to arouse the attention of the receiver. His concentrated effort to catch the intended meaning, and just the intended meaning, is apt to make him survey a series of *possibilities*. He may lose his intuitive understanding of the situation. Chances of misinterpretation may increase to such a degree that the need for further precization is acutely felt. The normally preconscious process of interpretation is rendered conscious and may result in awareness of difficulties of interpretation that had never occurred to the receivers of less complicated formulations.

All this is in no way to be considered fatal to efforts of precization as a means of avoiding misinterpretation, but it reminds us of the difficulties and of the unlimited manifold of subdirections of precization branching off from the main directions when the definiteness of intention grows. The quest for high definiteness of intention may, but need not, spoil the chances of successful communication.

II.8. Comparison of Preciseness of n Sentences in Relation to a Heteronymous Reference Class

We shall in this section conclude our discussion of reference classes by describing a comparison of n sentences as regards preciseness, within the same type of context and for the same class of persons, by means of heteronymous reference classes.

Let us call the sentences the preciseness of which is to be compared, T_1, T_2, \dots, T_n . A tentative, preliminary list of synonymic alternatives is made for T_1 , and modified until no pair of sentences in the list are synonymic alternatives of each other, whereas all are interpretations of T_1 . This requirement of heteronymity implies that each sentence is as precise as or more precise than T_1 , provided the list itself is taken as the reference class.

Let us call the individual synonymic alternatives listed R_1, R_2, \dots, R_m . We presume that synonymy questionnaires or other methods have been used to establish heteronymity between any pair.

The next step is to provide T_2 with an analogous tentative reference class. Sentences that already belong to the first class are not included in the second. The new class is modified until no synonymic alternative is a synonymic alternative of any other sentence in the two classes.

The rest of the sentences T_i are dealt with in the same way. All n reference classes are then combined into one large class R , and the preciseness of the individual T_i is found in relation to that class.

A sentence T_i is more precise than a sentence T_j in relation to R if there is at least one sentence in R that is an interpretation of T_j but not of T_i , and no sentence vice versa. The relation of preciseness implies that all sentences of R being interpretations of T_i must be interpretations of the less precise T_j . This interpretability is a necessary, but not sufficient condition of T_i being more precise than T_j . Thus, it is convenient first to see whether or not T_i satisfies this condition.

The comparison so far includes the following steps:

1. Making n preliminary lists of synonymic alternatives based on guesses (intuitions). (Preliminary reference classes.)
2. Eliminating, in other lists, formulations already adopted in one list. (Elimination of duplicates.)
3. Checking on heteronymity among the rest of the formulations and eliminating formulations that (sometimes or always) are synonymic alternatives of some other formulation of the total reference list, for example, eliminating total or partial synonymities from the preliminary reference class.
4. Testing supposed synonymity relations. Eliminating reference formulations that, according to the results of tests, are not synonymic alternatives of *any* of the formulations to be compared for preciseness. This process and that of step 3 often suggest the advisability of adding some formulations to the preliminary list.
5. Comparing preciseness in relation to the resulting revised reference class. (The final, first-order class.)

To improve the reference class, it is necessary to look for ambiguities. If a formulation R_i among the persons and situations at issue sometimes is considered synonymous with R_{i1} , and sometimes with R_{i2} , and the latter two formulations are considered heteronymous in all situations by all persons concerned, R_i may profitably be eliminated from the final, first-order reference class and replaced by the two sentences R_{i1} and R_{i2} . A new reference class is constructed by revision of the old.

II. BASIC TERMS CONTINUED

If we are interested in getting a reference class that, on the one hand, is as small as possible but, on the other hand, may prove to be a fair sample of richer reference classes, it is important to impose further checks on its members.

In relation to the new, more refined, and normally richer class, the relations of preciseness of the formulations to be compared may turn out to be different from the relations originally found.

The steps leading from a comparison on the basis of the first-order reference class to one of the second order may be indicated as follows. The steps are closely analogous to the steps leading to the first nonpreliminary reference class:

1. Making preliminary interpretational lists based on guesses, one list for each of the m formulations of the first-order reference list. Compared with the original interpretational list, these new lists are reference classes of a reference class. They will therefore be called «preliminary reference classes of the second order».
- 2–5. Following steps analogous to steps 2–5 described above.

With the new reference class as a starting point, one may proceed to construct still more refined classes, reaching, step-by-step, classes of the n th order. It is to be expected, however, that fewer changes in the conclusions regarding the preciseness of the n original formulations will result with each step toward higher-order reference classes. Further, the internal differences of meaning among the members will tend to be of less importance or will fall below the intentional depth of the persons whose usage is being investigated.

Suppose U is found less (intrapersonally) ambiguous than T for P_1 in S in relation to a reference class R , which is heteronymous in relation to the usage of P_1 .

If we now ask whether U is also less (intrapersonally) ambiguous for P_2 , we shall have, first, to check that R is a heteronymous reference class for P_2 . Second, we shall have to compare the preciseness of T and U in relation to R . If it is found that U is (intrapersonally) more precise than T , we have established two relations of intrapersonal ambiguity.

We may take these relations as strong support for a hypothesis that U is

interpersonally less ambiguous than T, but this depends on interpersonal synonymities. We do not yet know whether any member *r* of the reference class means the same to P_1 as any of them means to P_2 . In chapter 7, we take up the problem of how to introduce interpersonal synonymity operationally.

II.9. Preciseness of Single Acts of Communication

In chapter 1, we introduced a concept of a particular subclass of occurrences of «a» being more precise than a particular subclass of «b» (see section 12(2), page 64). We shall say that «a» is more *asserter-precise* for P_1 in S_1 than «b» is for P_2 in S_2 , if we limit our comparison of interpretations to those that are possible for P_1 as asserter of «a» and for P_2 as asserter of «b». Thus, we get a rather complex definitional formulation, the first part of which is given below under (1). It is obtained by substituting ««a» for P_1 as asserter of «a» in S_1 » for «a» and ««b» for P_2 as asserter of «b» in S_2 » for «b» in (1) on page 62.

- (1) If, and only if, every synonymic alternative to «a» for P_1 as asserter of «a» in S_1 is also a synonymic alternative to «b» for P_2 as asserter of «b» in S_2 , and . . . , then «a» will be said to be more asserter-precise for P_1 in S_1 than «b» is for P_2 in S_2 .

Receiver preciseness is introduced in the same way, *mutatis mutandis*.

The designation «asserter» refers to the person who performs the asserting. By that act, however, the asserter will normally be stimulated by the produced sounds or visual pattern. He will act as receiver and may change his formulations as a consequence of the impression his own assertion makes. It is, therefore, somewhat difficult and unfruitful to try to distinguish interpretations made by a person asserting a formulation and interpretations made by the same person as receiver of that formulation at a slightly later moment. There are, on the other hand, reasons to suspect that we as receivers very often repeat the message to ourselves. We stimulate ourselves to obtain stronger reactions than possible by the initial reception of the message. Especially if the formulations are somewhat difficult, it is normal to repeat more or less articulately what we hear or read.

For the purposes of this work, it is not deemed necessary to go into details as regards these interesting and complex problems of psychological

II. BASIC TERMS CONTINUED

descriptions. They will have to be attacked in future refinements of interpretational theory. Here, we limit ourselves to laying down that by an «act of assertion» we mean an act, one of the characteristics of which is speaking or writing. Analogously, we shall call a person «a receiver» if he is listening or reading, regardless of the subordinated acts of repetitions that we may find connected with the hearing or reading.

If S is a type of situation that often recurs, differences in level of asserter preciseness are easily exemplified. Let us take the trivial case of a person P saying «Coming home on the train at 6 o'clock» to his wife, who may represent part of S. Let us call the formulation «a». During certain time intervals, «a» may (for P) be synonymous with «Coming home on the train at 6 o'clock daylight saving time» («b»); during other time intervals, with «Coming home on the train at 6 o'clock standard time» («c»). If S is so defined that it includes all seasons of the year, «a» admits synonymic alternatives (as interpreted by P as an asserter) that «b» does not admit. If no synonymy between «b» and a formulation «d» is found, which to P as sender of «d» is a synonymic alternative of «b» but not of «a», we shall, according to the definition, say that «b» is for P as asserter in S more asserter-precise than «a» for P as asserter in S.

If, on the other hand, S is delimited in such a way that it falls well within the season of daylight saving time, «c» is probably not even occasionally synonymous with «a» for P as an asserter. In that case, «b» does not improve its asserter-preciseness in comparison to «a».

If S is successively made narrower and narrower, we get as a limiting case a single, datable occurrence of asserting. There is no longer a question of possibilities of interpretation under various circumstances, but of how «a» was interpreted on a particular occasion.

Somebody might suggest that only one interpretation is made on a single occasion. There may be only one *process of interpretation*. What is called «interpretation» in this work is what is expressed by a formulation with certain relations to some other formulations (see page 53).

If P₁ sends «a» and answers positively that he might have used «b» without change of meaning, and he also answers positively in relation to «c», we may infer that if he had asserted «b», he would have answered positively if confronted with «c». Actual experiments confirm this expectation. The relation of synonymic alternative as applied to the asserting of

formulations by one person in a single datable situation is empirically transitive.

Let S_1 symbolize a definite datable situation characterized by the occurrence of a single process of interpretation. We may then write:

- (2) $\text{Synalt}(aS_1bS_1) \supset \text{Syn}(aS_1bS_1)$
- (3) $\text{Synalt}(aS_1bS_1) \ \& \ \text{Synalt}(aS_1cS_1) \supset \text{Synalt}(bS_1cS_1)$
- (4) $\text{Synalt}(aS_1bS_1) \ \& \ \text{Synalt}(aS_1cS_1) \supset \text{Syn}(bS_1cS_1)$

If «b» is a synonymic alternative of «a» in S_1 , then all synonymic alternatives of «b» in S_1 will be synonymic alternatives of «a» in S_1 . This owes to the properties of the relation of synonymy:

- $(x)(y) . \text{Synalt}(xS_1yS_1) \supset \text{Syn}(xS_1yS_1)$
- $(x)(y)(z) . \text{Syn}(xS_1yS_1) \ \& \ \text{Syn}(xS_1zS_1) \supset \text{Syn}(yS_1zS_1)$

Therefore:

$$\text{Synalt}(bS_1aS_1) . \supset . (x) . \text{Synalt}(xS_1bS_1) \supset \text{Synalt}(xS_1aS_1)$$

If both «b» and «c» are synonymic alternatives of «a» in S_1 , all three will have exactly the same synonymic alternatives. From this and the normative definition of «preciseness» it follows that, in relation to S_1 , no expression can be more precise than any other. They will all be equally precise.

In symbols:

$$(x)(y) . \text{Synalt}(xS_1yS_1) \supset \text{Idpr}(xS_1yS_1)$$

From

$$\text{Amb}(a) \sim (Ei)(Ej) . \text{Het}(a_i a_j)$$

follows

$$\text{Amb}(aP_1S_1) \supset (Ei)\text{Het}(aP_1S_1a_iP_1S_1)$$

II. BASIC TERMS CONTINUED

But there is only one occurrence of «a» in S_1 ; therefore,

$$\text{Amb}(aP_1S_1) \supset \text{Het}(aP_1S_1aP_1S_1)$$

From which follows

$$\neg \text{Amb}(aP_1S_1)$$

That is, an occurrence of an expression sent by a particular act of communication in S_1 by P_1 cannot be asserter-ambiguous in relation to that person in that situation. No heteronymous reference list can be made in relation to that occurrence of «a», and one cannot construct lists of interpretations.

In relation to single acts of communication, there is no difference in preciseness for an asserter or a receiver. Differences of preciseness always refer to a multiplicity of acts of communication or to a multiplicity of persons, or to both.

This theorem is misleading if it is not clearly kept in mind how preciseness is defined and how single acts are contrasted with types of situations.

If a person tries to convey an assertion to another person, the choice of formulation may be fully subordinated to the single aim of asserting a formulation that, to the receiver, expresses just the proposition intended by the asserter, or a proposition within the least possible distance in meaning from the intended one. It is in relation to that purpose irrelevant which synonymic alternatives are possible to the asserter on any occasion except the one on which he tries by means of the chosen formulation to convey the assertion to the other person. Similarly, it is irrelevant how the receiver interprets the formulation on occasions other than the one at issue.

That a formulation is more precise than another does not imply that it is more precise within a particular type of situation for particular people.

It may well be that «b» is more precise than «a» in relation to a group of persons P and a type of situation S , but equally precise, or less precise, or incomparable as regards preciseness in relation to a subgroup of persons P or a subtype of situation S . Thus, to know about preciseness relations of great extension is neither necessary nor sufficient for the discovery of preciseness relations of smaller extension. Very little can be inferred about preciseness in relation to single acts.

These assertions do not hold if we look at preciseness relations between a formulation within a greater extension and the same formulation within a smaller extension of persons or situations.

If the preciseness of «a» is compared to the preciseness of «a» in a subclass of situations and persons, it is easily seen that it cannot be less precise in the subclasses than in the general class.

If the rectangle A B C D symbolizes all possible interpretations of «a», the interpretations possible to one person must either be the same or be a subclass, let us say those of the rectangle A B E F. For another person, the line corresponding to E F may go to the left, may go to the right, or may coincide with E F, thus creating relations of the type $\text{Pr}(aP_2S, aP_1S)$, $\text{Pr}(aP_1S, aP_2S)$, or $\text{Idpr}(aP_1S, aP_2S)$.

If S_1 is a type of situation, the possible interpretations of «a» for P_1 in S_1 may be identical with those in the rectangle A B E F, or may fall within a smaller rectangle, let us say A B G H. If S_2 is a singular historical situation, the rectangle of possible interpretations for P_1 may be identical with A B G H, or may be a still smaller one, say, A B I J.

Thus, if a formulation is insufficiently precise within a great group of persons or situations, it may be just as imprecise within smaller groups, but it may also be much more precise.

Sometimes very imprecise formulations in relation to broad fields may turn out to be excellent in relation to narrower ones. We may here think of scientific terminology using vernacular terms in new, well-defined meanings.

«More precise» in relation to *an act of communication* between two persons in a definite type of situation may be defined thus:

- (5) A formulation «b» is more precise than «a» in communication between P and Q in a situation S_1 partly defined by P being asserter and Q receiver, if and only if «b» is more precise than «a» for both P and Q in S_1 .

II. BASIC TERMS CONTINUED

If the connotation of «S» is steadily made richer, the limiting case is reached, namely asserter-receiver preciseness relative to single acts of communication. Using the results of this section, we find that in relation to single acts of communication, all synonymic alternatives are equally precise, even in the case of asserter-receiver preciseness.

II.10. The Limited Importance of Single Acts of Communication to a Science and Technique of Interpretation

The foregoing section may have conveyed to some readers the impression that the concepts of relations of preciseness are unfruitful concepts: we have always to do with single acts of communication, and in relation to them the concepts of preciseness are useless. A science and technique with the aim of describing and possibly eliminating misinterpretation might be considered unfruitful if not adapted to concrete, single acts of communication.

Against such views it must be emphasized that to make predictions about how to communicate with the best results, it is necessary to study *types* of situations, of habits of speech, of dispositions of groups, and so forth. Much knowledge from which predictions are made is in the form of more or less generalized sentences. Descriptions of single acts are mostly either reports of past events or predictions based on inferences from general descriptions. Our interest may be concentrated on single acts of communication, but the argumentation used to justify the choice of definite formulations on definite occasions is based on knowledge about kinds of formulations in kinds of situations. We use in such cases, as one of our premises, the assumption that the single act of communication will be released in a *kind* of situation and by a *kind* of person we know something about. If there is a relatively well confirmed hypothesis that «a» is more precise than «b» in that *kind* of situation, we may decide to use «a» in the single, always unique act of communication that will be released at a definite moment at a definite place. There is no knowledge available about *that* single act as contrasted to kinds (types, classes) of acts.

Even, however, if we succeed in adapting our formulations to a definite act of communication as contrasted to relatively broad classes of communications, this may not be of any help. Lack of misinterpretation at the time of the act of communication does not guarantee against misinterpretation at

II.11. Schematic View of Requirements of Communication to Many People

later moments. The conveyed information is normally supposed to be used a great number of times in a more or less distant future. If a person succeeds admirably at 10 A.M. in conveying to his son how to get to the bank, this does not rule out possible misunderstanding at 10:15 when the son has to recall the words of the father and make up his mind whether his description implied a left or a right turn at a particular corner. He will have to reconstruct the situation at 10 o'clock in his memory, but this does not mean that he repeats it. The singular situation at 10 A.M. may be *per definitionem* unrepeatable in its exact features. The words and gestures admirably fitted to the situation indoors at 10 o'clock may be confusing outdoors at 10:15. The purpose of a communication mostly presupposes that the formulations used are well adapted to future situations in which the receiver memorizes them or reads them anew. They must serve well in acts of self-stimulation under changing conditions. This purpose is of great importance in constructing scientific languages. Such languages presuppose that processes of self-stimulation take nearly identical courses in spite of great variations in situations.

In general, we may say that the success of a single act of communication between two persons at a definite moment is of relatively small importance compared to the importance of chains of communications in which the used formulations play a role. It is of importance, for understandable psychological and sociological reasons, that formulations are used that can be repeated in a variety of situations without marked changes in interpretation. We are, thus, forced back to the problem of finding formulations that are more precise than others within relatively broad types of situations.

II.11. Schematic View of Requirements of Communication to Many People

Let us suppose that a person P wishes to communicate as adequately as possible something he himself usually expresses by T. He wishes to communicate with n persons Q_1, \dots, Q_n , $n > 1$, each of whom may have slightly different training and social background from the others.

If T has the astonishing property of not being slightly or grossly ambiguous within this group of persons, and if P knows this, he may limit himself to utter T to them, and the communication is a complete semantical success.

II. BASIC TERMS CONTINUED

If the persons are expected to interpret T in different ways and too different for the purpose at hand, P may first look for a single sentence U that is interpreted in the same way by all. It will have to satisfy the following requirement:

$$\text{Syn}(\text{TPS}; UQ_1S) \& \text{Syn}(\text{TPS}; UQ_2S) \& \dots \& \text{Syn}(\text{TPS}; UQ_nS)$$

Or, in short

$$(i). \text{Syn}(\text{TPS}, UQ_iS)$$

If n is big, there is little chance that P will be able to find any U that satisfies the requirement of unambiguity. If he does not find any, he may study the usage of each person and find out how to express what he intends by T to each person separately, or in groups. This done, he may have to utter n different sentences, each addressed to one person:

$$\begin{array}{ll} T_1 \text{ to } Q_1: & \text{If } \text{Syn}(\text{TPS}; T_1Q_1S). \\ T_2 \text{ to } Q_2: & \text{If } \text{Syn}(\text{TPS}; T_2Q_2S). \\ \text{---} \text{ ---} \text{ ---} & \\ T_n \text{ to } Q_n: & \text{If } \text{Syn}(\text{TPS}; T_nQ_nS). \end{array}$$

The requirement fulfilled by the individual T_i does not imply that T_i is more precise than T for any person in any situation. T_i may be synonymous with very different sentences for different persons.

When we carry out works of popularization, it is of interest to study what kinds of considerations determine how far we consciously use formulations apt to be misunderstood in various ways, and what kinds of reasons we have for suspecting that some misunderstandings have fewer undesired consequences than others.

II.12. Relation Between Knowledge of Context and Preciseness

It seems to be generally accepted that a formulation should not be isolated from its context when interpreted and that the more we know about the context, the less likely it is that we hit on incorrect interpretations. It is

often stated that the so-called «exact» («real», «correct», «accurate») meaning can be gathered only by study of «the context as a whole». An objection often made to the method of interpreting a text by successive interpretation of its sentences is that the text must be taken as a whole, not analyzed into parts. Interpretation should, according to some people, proceed from a general view of the whole toward interpretation of each unit, not vice versa.

These are rather vague hypotheses. What can be maintained in a serious discussion of the matter, and how can it be formulated? Authors often complain that their critics interpret formulations «isolated» from the contexts. However, there seems to be much misunderstanding because some people regard things as belonging to the context, while others do not. On the whole, there is a tendency to look on greater parts of texts as the context of one's own formulations, compared to the context relevant in case of formulations produced by others.

Sentence (1) on page 62 is a member of a sequence of sentences making up a page of a book, and of a sequence making up section 12 of chapter 1. Chapter 1 may conveniently be regarded as the proper context to investigate when writing theses about the work of the author. The body of valid laws of a community is sometimes mentioned as the proper context for the interpretation of laws. On the other hand, sentences are sometimes said not to belong to the context that occurs within a few sentences of the one at issue.

So far, we have mentioned context in the form of sentences. Often, one also refers to other things as context, for instance, the purpose of a communication, the place where it is carried out, the expected audience, the sex, age, education of its author, and so forth. Anything may be mentioned that conceivably could have an effect on the interpretation of a sentence. Thus conceived, it would easily be an analytical proposition that the more one presupposed known about the context, the more precise would be the interpretation chosen.

It would be highly arbitrary to fix a limit between what is part of the verbal context of a sentence and what is outside the context. We shall here deal with sentences and contexts in general and need only the following definition.

Let S_1 and S_2 be two groups of sentences. S_2 includes S_1 and, in addition, at least one sentence not belonging to S_1 .

II. BASIC TERMS CONTINUED

(1) If a sentence is interpreted by a receiver on the basis of the group of sentences S_1 , it is said to be interpreted on the basis of a *narrower verbal context* than if the group S_2 is taken into consideration.

The age of the author of a sentence may be taken into account by making a sentence designating the age and making it a member of the group of sentences more or less arbitrarily selected as context.

Theorem:

(2) The broader the context taken into consideration by a group of receivers of a sentence, the more receiver-precise is the sentence within the group.

This theorem is not to be interpreted as saying that any broadening of context will favorably affect the level of preciseness, but that a broadening either will affect it favorably, or will not affect it at all.

It is easy to see that, even thus interpreted, the theorem will not hold in every case. Some formulations may be highly misleading, and to be ignorant of such formulations should therefore be a help rather than a hindrance. Sometimes we get more and more confused during the reading of a book.

Theorem (2) is a very general, vague, and trivial hypothesis, which, however, is useful as a starting point for important parts of the theory of interpretation.

If the consideration of a group of sentences S_1 will have more influence on the interpretation than the consideration of another group S_2 , S_1 will be more important to consider. In general, the more influence it has and the smaller it is, the more reason there is to take it into account.

II.13. Interpretational Vibrations Caused by Broadening the Context

We cannot get a total picture without reading a document sentence by sentence, interpreting small units as we read. It is, therefore, necessary to proceed from smaller units to greater, and then back again to smaller. This movement has sometimes been called «the hermeneutical circle».

The following schematic description aims to give a more adequate picture of the possible effects of successive broadening of context by reading.

It should help us realize how extremely complex are the possibilities of mutual influence of parts.

Let «a» be a sentence isolated from any direct auditory or visual verbal context. By Int(a), we symbolize in this section an interpretation of the sentence «a» put forward by a receiver of «a» as an attempt to express as precisely as possible (to him, the receiver) what he thinks the author of «a» has intended to convey by «a». By «b», we symbolize the first sentence of a verbal context now connected with «a». By Int(b), we symbolize an interpretation of «b», put forward by the receiver of «a» when he gets access to «b». By an expression of the kind Int(x,S:y), where «x» and «y» are expressions containing the symbols «b» and «a» or certain others, we symbolize an interpretation of «x» on the basis of «y», for example, with «y» as available context. Thus, Int(a,S:b) is read: the interpretation of «a» based on «b» as the context of «a».

By means of these symbols it is possible to give condensed formulas for the sources of shifts in interpretation when contexts are broadened. Other possible influences are neglected for the sake of simplicity. The formulas will, I hope, give a clear picture of the possible interactions between «total view» and «isolated interpretation of small units».

To the left are the symbols of interpretations and contexts available when the reader (receiver) proceeds as indicated to the right.

«a»	Reader perceives the formulation «a» and
Int(a)	interprets it without looking for a context. He then turns on a formulation «b»
	making up the immediate verbal context
Int(b,S:a)	of «a» and interprets it, but is hereby possibly influenced by «a». After the interpretation of the immediate context of «a», this formulation is no longer
Int(a,S:(b,S:a))	isolated, and reinterpretation is needed. But his interpretation of «b» was possibly influenced by his original interpretation of «a».
Int(b,S:(a,S:(b,S:a)))	Possibly the new interpretation of «a» will influence his interpretation of «b», and he gets a modified interpretation of that formulation. This new interpretation of «b» may possibly lead to reinterpretation of «a», and so on.

Let us suppose that oscillations between «a» and «b» following upon those illustrated do not result in any change of interpretation of «a» and «b». We may then stop at the last interpretations of the diagram.

II. BASIC TERMS CONTINUED

As a next step, we now introduce a new sentence, «c», as the immediate verbal context of «b». The interpretation of it will be influenced by the already-interpreted sentences «a» and «b» that make up its context:

$$\text{Int}(c, S: [(b, S: (a, S: (b, S: a))) \& (a, S: (b, S: a))])$$

Let us, in the following, use A as an abbreviation for the expression in square brackets.

Now, however, «a» and «b» are viewed in the light of the new context «c», interpreted as symbolized above. Possibly this modifies the interpretation of them, and we get the two new interpretations:

$$\text{Int}(a, S: [c, S: A])$$

$$\text{Int}(b, S: [c, S: A])$$

The new interpretation of «a» may possibly influence that of «b», and the new interpretation of «b» may possibly influence «a». Let us instead look at the possibility that the new interpretations of «a» and «b» will influence the interpretation of «c». This sentence was originally interpreted on another basis than the latest interpretations of «a» and «b» and we may possibly have to work with a new interpretation of «c»:

$$\text{Int}(c, S: [(a, S: [c, S: A]) \& (b, S: [c, S: A])])$$

The functional interdependencies with increasing number of sentences increase very fast, so that the schematical picture of the relationships soon becomes practically impossible to handle. A new sentence may unsettle any one of the previous interpretations. In practice, there are, on the other hand, slight chances that a single addition to a context gives rise to many and important changes.

If a treatise is built up by an argumentation consisting of n sentences, which are read successively, we eventually arrive at an interpretation of its first sentence in the light of the n–1 following sentences as context. If this «total view» context changes our previous interpretation of the first sentence, then it is necessary to take up the «total view» context for renewed interpretation, since it has been subjected to an outdated interpretation of

the first sentence. Thus, one will have to revise the «total view» on the basis of less comprehensive interpretations, namely the interpretation of the first sentence.

Discussions about context and interpretation seem to some degree thwarted by the implicit assumption that a sentence may be «viewed» in a broad verbal context, without this context being laboriously interpreted. Each interpretation is a function of other interpretations, and only indirectly a function of «context» in the sense of surrounding formulations in contrast to surrounding assertions.

The preceding illustrations are based on the simplifying assumption that the receiver (for example, a reader of a book) chooses one and only one interpretation when he is confronted with a sentence. He is supposed consciously or nonconsciously to single out one interpretation as the most plausible on the basis of the available material. If, however, the receiver's task is to read a textbook of philosophy, a sermon, or a rhetorical masterpiece, he may find the sentences ambiguous (even when the available context is taken into account), and he will suspend judgment as regards definite interpretation until more context is available. He may decide to work with several possibilities of interpretation, without showing any preference. Let us see how we can illustrate this more realistic account of the interpretational efforts of the reader. Let $\text{Int}_1(a)$, $\text{Int}_2(a)$, . . . , $\text{Int}_n(a)$ be the n interpretations of « a » that the reader cannot distinguish as regards degree of plausibility, all being approximately equally plausible in view of the lack of contextual information. When he proceeds to the context formulation « b », it is interpreted in the light of « a », which gives the following possibilities:

$$\begin{aligned} &\text{Int}_1(b, S: \text{Int}_1(a)) \text{Int}_1(b, S: \text{Int}_2(a)) \dots \text{Int}_1(b, S: \text{Int}_n(a)) \\ &\text{Int}_2(b, S: \text{Int}_1(a)) \text{Int}_2(b, S: \text{Int}_2(a)) \dots \text{Int}_2(b, S: \text{Int}_n(a)) \end{aligned}$$

Suspension of interpretation, even if relating to only two sentences, may create a vast manifold of possibilities. In practice, these are not verbalized, but some of them must be reckoned with as causal factors regulating interpretation of «difficult» texts by analysts. In the case of interpretation of imperfectly known languages, linguistic research sometimes leads to explicit formulation of vast numbers of possibilities. Normally, however, we

II. BASIC TERMS CONTINUED

rather seem to have a nonverbalized disposition for varieties of possibilities, which is changed without our noticing it.

Concluding, we should like to emphasize that the above schemes are not psychological descriptions of how texts are interpreted, but a survey of how interpretations of large units of texts depend on interpretations of smaller units, and vice versa.

The often-heard complaint that interpretations must proceed from «views of totality», from «comprehensive understanding, not from atomic disintegration of texts» ought not to be used as a justification for a reversion to nonconscious interpretation, unenlightened by any effort to find out how and why we arrive at our ultimate choice of interpretation of any unit of text. On the other hand, there is a danger that very painstaking analysis of possibilities makes us unable to complete the reading of texts if they are not written in unusually precise language. The number of possibilities of interpretation may be practically unlimited in case of texts of comparatively low levels of preciseness.

Against the unwarranted principle of interpretation from the «totality», one may place the «*principle of the hermeneutical circle*»: from interpretation of isolated expressions, one proceeds to more and more comprehensive wholes, then back again to each isolated expression. From isolated expressions, the interpreter again attempts to survey wholes. The term «hermeneutical circle» is suggested by F. Torm (1938: 158); the principle had possibly been suggested already in 1808 by F. Ast.

II.14. Synonymity and Preciseness of Imperatives

We have so far limited our analyses to declarative sentences (formulations) and designations.

This limitation has been only temporary. We shall briefly indicate how to extend the theories to other types of sentences. It should be borne in mind, however, that the limitation imposed so far has not excluded from consideration parts of sentences other than formulations. Designations included in imperatives, in questions, and in any other type of sign-complexes that normally do not express assertions are included in the scope of definitions and theorems on «designations» as this word is used in chapter 1. If, for example, a question is misunderstood, it is feasible and it is a

normal procedure to try to make one or more designations included in the question more precise or more specified. There are, in the foregoing sections, introduced tools relevant to the theory of norms and of questions.

Suppose «a!» is a sentence that does not for P in S express any assertion but rather a command or request or decision (an «imperative») made by the person pronouncing «a!», or interpreted to be a command or request by some other person or personalized institution.

- (1) Two sentences, «a!» and «b!», are in this work said to express the same imperative for a person P in a situation S if, and only if, every expression T—which, according to P in S designates a satisfaction of «a!»—also designates a satisfaction of «b!», and vice versa; and every expression U—which, to P in S designates a nonsatisfaction of «a!»—also designates a nonsatisfaction of «b!», and vice versa.

Two sentences satisfying (1) we call «synonymous imperative sentences for P in S».

The formulation «An expression T designates according to P in S a state of satisfaction of the imperative «a!»» admits of two directions of precization worthy of being mentioned in this connection. One direction may be suggested by making the formulation synonymous with «P considers the state characterized by T to be realized *as a result* of the announcement «a!»». The other direction may be suggested by making the formulation synonymous with «T designates according to P in S a state of affairs confirming the assertion that «a!» has been followed».

The difference between the two directions is between the satisfaction of an imperative and the state of affairs and the announcement of the imperative and the state of affairs, T. If the satisfaction clause is precized in the second direction, there may be no causal link whatsoever.

If, to take an example, the imperative is the one I herewith announce: «Let there be no pirates in the Arctic Sea!», the sentence «There are no pirates in the Arctic Sea» represents an expression T of the kind demanded by the second direction of precization. It is, by me, considered to confirm the hypothesis that my imperative has already been followed. There has not been any causal chain between my imperative and the condition in the Arctic, however. Thus, the condition cannot be said to be a result of the imperative.

II. BASIC TERMS CONTINUED

Both directions of precization lead to concepts of some fruitfulness. There is no reason at the present stage of the introduction of conceptual structure to eliminate any of them by a decision in favor of any other.

To illustrate definitional formulation (1), we may select the following «constants»:

«a!»	in this work, the word «interpretation» shall be used as indicated in chapter 1
«b!»	in the work in which this sentence occurs, the word «interpretation» shall be used as indicated in chapter 1 of that work
P	A. N.
S	this page

I think there is no designation that weakens the requirement of (1). As an example of a pair of confirmatory formulations, we select the following:

- T₁: In this work, the word «interpretation» is used as indicated in chapter 1.
- T₂: In the work in which this sentence occurs, the word «interpretation» is not used as indicated in chapter 1 of that work.

The formulations T₁ and T₂ have an important relation to any expression that might satisfy (1). If T_i is a designation satisfying (1) provided «a!», «b!», P, and S are exemplified as in the illustration, in that case T_i has a connotation equal to or richer than T₂. This I judge from knowledge of my own verbal habits. We shall call an expression fulfilling the requirement of having a connotation not less rich than any other satisfying (1) *an expression of conditions of complete realization* of the imperative at hand.

Considerations of fruitfulness and economy of thought have led us to adopt concepts of interpretation and preciseness of imperatives that are closely analogous to those used in relation to formulations. Thus, by analogy with (1) on page 57, we write:

- (2) «The imperative «a!» is a synonymic alternative to the imperative «b!»» shall in this work mean the same as ««a!» and «b!» may be synonymous».

On the basis of this terminology, the other definitions and theorems of chapter 1 about interpretation and so forth are made, *mutatis mutandis*, applicable to imperatives.

By analogy with (1) on page 62, we get:

- (3) If, and only if, every synonymic alternative to the imperative «a!» is also a synonymic alternative to the imperative «b!», and there is at least one synonymic alternative to «b!» that is not a synonymic alternative to «a!», and «a!» admits of at least one synonymic alternative, then «a!» will be said to be *more precise* than «b!».

By means of this terminology, the sentences about preciseness of formulations in chapters 1 and 2 may, *mutatis mutandis*, be used about preciseness of imperatives.

II.15. Synonymity and Preciseness of Questions

We shall try to «reduce» the analysis of questions to the analysis of assertions in much the same way that we have just done with regard to imperatives.

- (1) Two sentences «a?» and «b?» are in this work said to be synonymous or to express the same question for a person P in a situation S if, and only if, every formulation T that expresses for P in S a positive answer to «a?» also for P in S expresses a positive answer to «b?», and vice versa; and every formulation U that expresses for P in S a negative answer to «a?» also for P in S expresses a negative answer to «b?», and vice versa.

By analogy with (1) on page 57, we get:

- (2) «The question-sentence «a?» is a synonymic alternative to the question-sentence «b?»» shall in this work mean the same as ««a?» and «b?» may be synonymous».
- (3) If, and only if, every synonymic alternative to the question «a?» is also a synonymic alternative to the question «b?», and there is at least one synonymic alternative to «b?» that is not a synonymic alternative to «a?», and «a?» admits of at least one synonymic alternative, then «a?» will be said to be *more precise* than «b?».

II. BASIC TERMS CONTINUED

(4) If, and only if, every formulation expressing a positive (or negative) answer to the question «a?» also expresses a positive (or negative) answer to the question «b?», and there is at least one positive (or negative) answer to «b?» that does not express a positive (or negative) answer to «a?», and «a?» admits of at least one positive (or negative) answer, then «a?» will be said to be *more precise* than «b?».

By means of the concepts of sections 14 and 15 we can deal with problems of interpretation and preciseness of imperatives and questions in a preliminary way adapted to our main purposes, which are concerned with concepts and assertions, rather than norms and questions.

III

Misinterpretation and Pseudoagreement

III.1. To Assent and to Agree: Verbal Agreement

Let us suppose that a person P tries to communicate to another person Q a proposition and the standpoint that this proposition is tenable. Let us further suppose that P tries to express it by a sentence T_0 , and that Q reacts positively in such a way as to indicate «agreement» with P. This *act of assenting* may be performed by means of words such as «yes», «sure», «certainly», «agreed», and «that is so», or by nodding or other socially accepted gestures of assenting. For the sake of simplicity, we shall in this chapter assume that Q responds verbally and in such a way that we may with great certainty infer that Q regards as tenable that proposition that he believes P tries to convey to him. In symbols:

(1) $\text{Ass}(PT_0Q)$

(2) $\text{Ass}(QT_0P)$

The symbol «Ass» is used to symbolize assertion.

The whole symbol « $\text{Ass}(PT_0Q)$ » reads, P asserts T_0 with Q as intended receiver(s).

The whole sign-complex (1) and (2) is a description of an attempt at communication. This and later symbolizations in this chapter are all symbolizations of what an analyst observes or infers.

Whenever an interaction between P and Q occurs in such a way as to make the above symbolization adequate, we shall say that at step (2) and in relation to the sequence of steps (1), (2), there is *verbal agreement* between P and Q. The observational basis is in such cases usually an act of assenting. If

III. MISINTERPRETATION AND PSEUDOAGREEMENT

neither P nor Q comments on the other's use of T_0 , we shall infer that at step (2) P and Q believe that they interpret T_0 in the same way, or that they, if asked, and if they understood the question, would be willing to assert that they assume they interpret T_0 in the same way. («Same» is here open to different, more or less exacting interpretations, which generate various more or less strong assumptions on the part of the analyst.) Further, we, as analysts, infer that Q believes to be tenable the proposition that he thinks P tries to express by T_0 . Further, we infer that P believes that Q, by his answer, has indicated that he accepts the proposition that P intended to convey.

Sometimes the inferences may be checked carefully and found well supported, but this usually requires extensive investigations.

We talk about «steps» in the sense of successive verbal utterances in a sequence making up a discussion, deliberation, or some other kind of verbal communication between different persons, or, as a limiting case, within the same person at different moments. The successive steps may be described in terms of situations in the terminology of the preceding chapters.

If Q responds negatively in such a way as to indicate that he does not consider that the proposition he believes P is trying to convey to him is tenable, we shall say that there is *verbal disagreement* between P and Q at stage (2) and in relation to the sequence (3), (4). We symbolize this as follows:

- (3) (1) Ass(PT_0Q)
 (4) (2a) Ass($Q-T_0P$)

or

- (4) (2b) \neg (Ass(QT_0P))

The alternative (2b) indicates that Q limits himself to indicating that he is not willing to assert T_0 . Maybe he considers T_0 to be devoid of meaning or too ambiguous to be accepted or rejected, or he may consider the negation of T_0 to be tenable. If, and only if, this last possibility is indicated by Q's answer do we write (2a). In the following we shall, for the sake of simplicity, limit ourselves to discussions in which persons assert either T_0 or its negation.

III.2. Pseudoagreement and Pseudodisagreement

Let us continue the analysis of discussions starting with the two steps:

(1) Ass(PT_0Q)

(2) Ass(QT_0P)

If T_0 for P is interpersonally synonymous with T_0 for Q at step (2), then we shall say that at step (2) there is *expressed interpersonal and propositional agreement* between P and Q in relation to the sequence (1), (2), and as regards the proposition expressed by T_0 by P. The concept is formed by precization of expressions such as «real agreement» and «agreement not owing to confusion of terminology».

If T_0 for P is interpersonally synonymous with T_0 for Q at step (2a) of the sequence (3), (4), section 1, we shall say that at step (2a) there is *expressed interpersonal and propositional disagreement* between P and Q in relation to the sequence (3), (4) and as regards the proposition expressed by T_0 by P.

If T_0 as interpreted by P is not interpersonally synonymous with T_0 for Q at step (2), and T_0 expresses a proposition for Q that is different from the one expressed by T_0 for P, then we shall say that there is at step (2) *pseudoexpressed agreement* between P and Q as regards the proposition expressed by T_0 for P. By that technical term we indicate that there is verbal agreement, a kind of situation normally taken to indicate propositional agreement, but that the situation is misleading because P and Q are talking about different things. It *seems* as if they explicitly are accepting the same standpoint—and they believe they have—whereas they are not accepting the same as far as can be judged by what they have tried to communicate to each other.

If we can, on the basis of sources of knowledge other than the symbolized communication, say that Q believes that the proposition expressed by T_0 for P is tenable, then there is propositional agreement at step (2), but, nonetheless, a pseudoexpressed agreement. If Q believes that proposition to be untenable, there is at stage (2) pseudoexpressed agreement connected with propositional disagreement. We shall in that case say that there is *pseudoagreement* at step (2).

If cases of verbal disagreement are similarly treated, the following cases shall have to be distinguished. They are all defined in relation to defi-

III. MISINTERPRETATION AND PSEUDOAGREEMENT

nite types of situations, those characterized by the succession (1), (2) of steps in a communication between P and Q.

Verbal Agreement at Step (2)

- A1 Verbal agreement and interpersonal synonymy give:
«expressed (communicated, conveyed) propositional agreement».
- A2 Verbal agreement and lack of interpersonal synonymy and propositional agreement give:
- A2.1 «pseudoexpressed propositional agreement».

Verbal agreement and lack of interpersonal synonymy and propositional disagreement give:

- A2.2 «pseudoagreement».

Verbal Disagreement at Step (2)

- B1 Verbal disagreement and interpersonal synonymy give:
«expressed (conveyed, communicated) propositional disagreement».
- B2 Verbal disagreement and lack of interpersonal synonymy and propositional disagreement give:
- B2.1 «pseudoexpressed propositional disagreement».

Verbal disagreement and lack of interpersonal synonymy and propositional agreement give:

- B2.2 «pseudodisagreement».

The distinctions introduced are more easily surveyed if formulated in symbols. It must be borne in mind, however, that some of the members of the conjunctions below refer to step (1), and some to step (2) or later steps. Thus, we may write:

- | | | | |
|------|----------------|------------------|-----------------------------|
| A1 | Ass(PT_0Q) | & Ass(QT_0P) | & Syn(T_0PS , T_0QS) |
| A2.1 | Ass(PT_0Q) | & Ass(QT_0P) | & -Syn(T_0PS , T_0QS) |

III.2. Pseudoagreement and Pseudodisagreement

	& Ass(QT ₁ P)	& Syn(T ₁ PS, T ₁ QS)	& Syn(T ₀ T ₁ PS)
A2.2	Ass(PT ₀ Q)	& Ass(QT ₀ P)	& -Syn(T ₀ PS, T ₀ QS)
	& Ass(Q-T ₁ P)	& Syn(T ₁ PS, T ₁ QS)	& Syn(T ₀ T ₁ PS)
B1	Ass(PT ₀ Q)	& Ass(Q-T ₀ P)	& Syn(T ₀ PS, T ₀ QS)
B2.1	Ass(PT ₀ Q)	& Ass(Q-T ₀ P)	& -Syn(T ₀ PS, T ₀ QS)
	& Ass(Q-T ₁ P)	& Syn(T ₁ PS, T ₁ QS)	& Syn(T ₀ T ₁ PS)
B2.2	Ass(PT ₀ Q)	& Ass(Q-T ₀ P)	& -Syn(T ₀ PS, T ₀ QS)
	& Ass(QT ₁ P)	& Syn(T ₁ PS, T ₁ QS)	& Syn(T ₀ T ₁ PS)

In the succession of steps (1), (2), P opens the discussion and Q acts as a receiver. Talking about propositional agreement, we always in such cases refer to propositions that the person who opens the discussion tries to express.

If both P and Q are receivers in a situation S, we may still as analysts talk about propositional «agreement» or «disagreement» between P and Q in S, but it is to be remembered that in this case there is no attempt to communicate between P and Q. The «agreement», therefore, does not extend beyond simultaneous implicit acceptance of a proposition, or, more accurately, a state of affairs characterized by two or more persons having the opinion that a certain proposition is tenable. In this chapter we are mainly concerned with attempts at communication, and our definitions and theorems are mainly concerned with types of steps in discussions.

It may happen that both P and Q read or hear T₀ without there being any person as sender, and P asks Q whether Q agrees to T₀, and P then indicates his own attitude. Under these circumstances, the cases A1, A2.1, and A2.2 shall refer to agreement about two propositions, the one P intends and the one Q intends.

Short illustrations of the distinctions introduced:

- (3) P: Nothing exists.
- (4) Q: You are wrong. Your foolish assertion exists.
- (5) P: I meant, nothing exists in the sense of Parmenides.
- (6) Q: I agree, but why did you not say that at once instead of saying something quasi-profound?

III. MISINTERPRETATION AND PSEUDOAGREEMENT

At step (4) we have a case of verbal disagreement. At step (5) P introduces a « T_1 », presumably chosen among precisizations of T_0 for P and with the hope that T_1 for Q means the same as it does for P.

At step (6) we may say that in relation to the succession (3)–(6), there was at step (4) a misinterpretation on the part of Q. There was at that stage of the discussion a pseudodisagreement. If the aim of P, to make more precise what he intended to express at step (3), is presumed to be successful at step (6), there is at that stage propositional agreement. We may, however, say that *there are symptoms* of propositional agreement at (6) and pseudodisagreement at (4).

- (7) P: Some assertions are absolutely true.
- (8) Q: No. We have not sufficient confirmation of any assertion to make its absolute truth plausible.
- (9) P: I meant, there are some assertions that nobody can seriously doubt.
- (10) Q: Oh, is that what you mean? I think that is an implausible psychological hypothesis.

We may, in relation to the succession (7)–(10), say that at step (8) there was verbal disagreement and at step (10) symptoms of pseudoexpressed propositional disagreement—that is, symptoms of case B2.1 of our tabulations on page 141.

III.3. Communications That Show Symptoms of Pseudoagreement and Other Undesired Properties

In the symbolized types of communication

- (1a) $\text{Ass}(PT_0Q)$ (2a) $\text{Ass}(QT_0P)$

and

- (1b) $\text{Ass}(PT_0Q)$ (2b) $\text{Ass}(Q-T_0P)$

there is nothing explicitly mentioned that could indicate that the attempt to convey a proposition was a failure. The analyst who maintains that it was

III.3. *Communications That Show Symptoms of Pseudoagreement*

a failure must have some material other than the utterances symbolized to prove his thesis.

Let us suppose that P continues the communication by one of the following types of sentences:

(3a) P: By T_0 I meant T_1 .

or

(3b) P: By T_0 I meant T_1 , not T_2 .

or, in previously introduced symbols:¹

(3as) Ass {P, Syn ($T_0T_1P(1)$), Q}

(3bs) Ass {P, Syn($T_0T_1P(1)$) & -Syn ($T_0T_2P(1)$), Q}

By means of (3b), P may indicate that a certain interpretation T_2 , which he thinks Q possibly has used, is not in harmony with his intention. Another interpretation, T_1 , which we safely may assume is heteronymous with T_2 for P, is offered as expressing his intention.

Offering T_1 instead of T_2 as a suitable formulation, P may have had the opinion that Q possibly interprets T_0 to mean the same as P means by T_2 , or perhaps the same as P means by T_1 . By substituting T_1 for T_0 , he tries to eliminate the possibility that Q interprets T_0 to mean the same as P means by T_2 .

Let us assume that Q answers P's assertion (3b) with one of the following sentences:

(4a) Q: That is how I interpreted your statement.

or

(4b) Q: I thought you meant T_2 by T_0 , not T_1 .

or

(4c) Q: To me T_0 , T_1 , and T_2 mean the same.

III. MISINTERPRETATION AND PSEUDOAGREEMENT

or

(4d) Q: To me, T_1 and T_2 mean the same, but something different from T_0 .

Or, in symbols:

(4as) Ass [Q, Syn($T_0P(i)$, $T_1Q(i)$), P]

(4bs) Ass [Q, Syn($T_0P(i)$, $T_2Q(i)$), P]

(4cs) Ass [Q, Syn($T_0T_1Q(i)$, (4)) & Syn($T_0T_2Q(i)$, (4))
& Syn($T_1T_2Q(i)$, (4)), P]

(4ds) Ass [Q, -Syn($T_0T_1Q(i)$, (4)) & -Syn($T_0T_2Q(i)$, (4))
& Syn($T_1T_2Q(i)$, (4)), P]

In the first case, (4a), there is a confirmation that Q interprets P as he himself does, a symptom of interpersonal agreement or disagreement and, hence, of «communication of propositions», another name for «expressed propositional agreement or disagreement». The confirmation cannot be considered to be very strong, however. On the other hand, we get relatively strong confirmation of two intrapersonal synonymities, Syn(T_0T_1PS) and Syn(T_0T_1QS). We have some reason to believe that T_1 is for P and Q in S less ambiguous than T_0 . It is this pair of intrapersonal synonymities that makes us look on the answer (4a) as a slight confirmation that there is an interpersonal synonymity Syn(T_0PS , T_0QS). Our assumption is that because T_1 is offered instead of T_0 , this means that T_1 was selected on the basis of a more sustained effort to arrive at effective communication. Therefore, there should be a better chance that we have Syn(T_1PS , T_1QS) than that we have Syn(T_0PS , T_0QS). Moreover, since Q says that he interpreted T_0 to mean the same as T_1 , we may transfer our confidence from T_1 to T_0 .

The use of (4a) as confirmation of interpersonal synonymity and, hence, of propositional agreement is almost universal in spite of obvious shortcomings.

In most discussions, even within the exact sciences, the participants use weak symptoms of propositional agreement, and we do not blame them. *What we here try to do is only to make more explicit the kinds of assumptions habitually made.* A clarification of this kind tends to increase the capacity to

III.3. *Communications That Show Symptoms of Pseudoagreement*

detect and eliminate misunderstandings that result from overestimating the certainty of these assumptions.

In all the other listed cases of step (4), there is material suggesting misinterpretation and lack of confirmation of the effectiveness of the attempted communication.

In case (4b) we may safely assume that T_2 and T_1 for Q are not synonymous. There has been interpersonal *misinterpretation* at step (2), provided T_2 does not mean to Q the same as T_1 to P, for example, if it was not the case that $\text{Syn}(T_1\text{PS}, T_2\text{QS})$. There is, however, nothing that suggests such an interpersonal synonymy. If Q agreed with P as to T_0 , there has been at step (2) either pseudoexpressed propositional agreement A2.1 or pseudoagreement (verbal agreement and propositional disagreement) A2.2. If, after step (4d), as a fifth step, we observe

(5a) Ass (QT_1P)

this is a strong symptom that there was at step (2a) pseudoexpressed propositional agreement about «a». From (2a) and (4b) we may infer that Q accepts the proposition expressed by T_2 for Q. P may or may not accept that proposition. If we observe

(5b) Ass($Q-T_1P$)

this is a strong symptom that there was at step (2a) pseudoagreement about T_0 .

If Q disagreed with P as regards T_0 , there was at step (2b) pseudodisagreement if (5a) holds good, pseudoexpressed propositional disagreement if (5b) is observed. It is of importance to note that there must be a fifth step to get material concerning pseudoagreement, etc. Steps (3) and (4) give us material to judge relations of synonymy and lack of synonymy, not to judge standpoints toward the propositions at issue.

Case (4c), in which Q maintains that T_0 , T_1 , and T_2 mean the same to him, reveals a difference between two systems of intrapersonal synonymies. The difference vitiates the use of step (3) for confirmation of effectiveness of communication. Something similar applies to (4d). T_1 and T_2 are not suitable to be used as «clarifiers». P may try out a new pair of formulations, for example, by saying

III. MISINTERPRETATION AND PSEUDOAGREEMENT

(6a) P: By T_1 I meant T_3 , not T_4 ; by T_2 I meant T_4 , not T_3 .

or simply

(6b) P: By T_0 I meant T_3 , not T_4 .

By these assertions, P brings in a new synonymy relation, presumably on the basis of a hypothesis that the new formulation, T_3 , is more apt than T_1 to be used in the same sense by both P and Q.

In view of the somewhat complicated structure of the possibilities opened up by a fifth and sixth step, we shall summarize the foregoing kinds of steps as follows:

(1) P: T_0

(2a) Q: T_0

(2b) Q: $\neg T_0$

(3) P: $\text{Syn}(T_0T_1) \& \neg \text{Syn}(T_0T_2)$

(4a) Q: $\text{Syn}(T_0T_1) \& \neg \text{Syn}(T_0T_2)$

(4b) & (5a) Q: $\text{Syn}(T_0T_2) \& \neg \text{Syn}(T_0T_1) \& \text{Q: } T_1$

(4b) & (5b) Q: $\text{Syn}(T_0T_2) \& \neg \text{Syn}(T_0T_1) \& \text{Q: } \neg T_1$

If (2a) and (4b) & (5a), there is at step (5a) a symptom of pseudoexpressed propositional agreement at step (2a).

If (2a) and (4b) & (5b), there is at step (5b) a symptom of pseudoagreement at step (2a).

If (2b) and (4b) & (5a), there is at step (5a) a symptom of pseudodisagreement at step (2b).

If (2b) and (4b) & (5b), there is at step (5b) a symptom of pseudoexpressed propositional disagreement at step (2b).

Further efforts of communication may confirm the hypotheses about pseudoagreement, etc.² Let us analyze the following kinds of additional steps. We shall assume that the first three steps were (1), (2a), and (3).

(6a) P: $\text{Syn}(T_1T_3) \& \neg \text{Syn}(T_1T_4) \& \text{Syn}(T_2T_4) \& \neg \text{Syn}(T_2T_3)$

(7a) Q: $\text{Syn}(T_1T_3) \& \neg \text{Syn}(T_1T_4) \& \text{Syn}(T_2T_4) \& \neg \text{Syn}(T_2T_3)$

III.3. *Communications That Show Symptoms of Pseudoagreement*

(7b) & (8a) Q: $\text{Syn}(T_1 T_4) \& \text{-Syn}(T_1 T_3) \& \text{Syn}(T_2 T_3) \& \text{-Syn}(T_2 T_4)$
 .&. Q: T_3
 (7b) & (8b) Q: $\text{Syn}(T_1 T_4) \& \text{-Syn}(T_1 T_3) \& \text{Syn}(T_2 T_3) \& \text{-Syn}(T_2 T_4)$
 .&. Q: $\text{-}T_3$

Steps (6a) and (7a) confirm the hypothesis motivated by (4a) that there was at step (2a) propositional agreement about the proposition expressed by T_0 for P.

The combination of (6a) and (7a) with (4b) and (5a) gives a confirmation of expressed propositional agreement at (5a) when Q asserted T_1 .

The combination of (6a) and (7a) with (4b) and (5b) gives a confirmation of expressed propositional disagreement at step (5b).

The combination of (6a) and (7b) and (8a) with (4a) weakens the status at step (4a) of the hypothesis that there was at step (2a) a propositional agreement as regards T_0 . This hypothesis was strengthened by step (4a), but T_1 and T_2 were by (7b) discovered to be interpreted differently. However, at step (8a) Q accepts T_3 , which to P is synonymous with T_0 . The status of the hypothesis may at step (8a) be regarded as somewhat stronger than at step (2a).

The combination of (6a) and (7b) and (8b) with (4a) weakens considerably the hypothesis at step (4a) that there was propositional agreement at step (2a). The amount of strength gained by step (4a) is lost again by steps (7b) and (8b).

There are, as may be gathered from the above indication, a great number of sequences that are relevant to the hypotheses of propositional agreement, pseudoexpressed propositional agreement, pseudoagreement, etc., at steps (2a), (4a), and so on. There is in theory no limit to the succession of confirmations and disconfirmations. In practice, however, there is a tendency to cut the sequences whenever confirmation is judged strong enough for the purposes at hand, or the differences in meaning between a pair of possible heteronyms (T_{2i-1}, T_{2i}) are judged sufficiently small. Or, the participants adopt methods of judging efficiency of communication other than that of comparing synonyms.

In the foregoing we have not discussed closely why we may take «agreement» about T_1 more seriously than «agreement» about T_0 . We have said

III. MISINTERPRETATION AND PSEUDOAGREEMENT

that the choice of T_1 as a means of communication is probably based on deeper reflection than the choice of T_0 . The capacity of steps (3) and (6) to *clear up misunderstandings* depends to some degree on the properties of T_1 and T_3 compared with that of T_0 . Here the theory of preciseness comes in, especially that of interpersonal preciseness.

III.4. Some Important Types of Sequences of Steps in Discussions

In the preceding section we analyzed some types of steps in a communication between two persons P and Q. P's purpose was to convey to Q that he thinks a certain proposition tenable and to learn whether Q agrees with him on the status of that proposition.

The sequence of steps (1), (2a), (3), (4a), (5a), (6a) may be viewed as the first steps in an unlimited sequence:

- (1) P: T_0
- (2a) Q: T_0
- (3) P: $\text{Syn}(T_0T_1) \ \& \ -\text{Syn}(T_0T_2)$
- (4a) Q: (3)
- (5a) P: $\text{Syn}(T_1T_3) \ \& \ -\text{Syn}(T_1T_4) \ \& \ \text{Syn}(T_2T_4) \ \& \ -\text{Syn}(T_2T_3)$
- (6a) Q: (5a)
- — —
- — —
- (2i+1) P: $\text{Syn}(T_{2i-3}T_{2i-1}) \ \& \ -\text{Syn}(T_{2-3}T_{2i}) \quad i = 2$
 $\ \& \ \text{Syn}(T_{2i-2}T_{2i}) \ \& \ -\text{Syn}(T_{2-2}T_{2i-1})$
- (2i+2) Q: (2i+1)
- — —
- — —

If the successive steps are carried out to eliminate ambiguities, we may predict that the larger the number of steps, the less likely it is that discussions involving T_0 will reveal a difference between the intended meaning of P and that of Q.

There is another type of sequence of equal importance, the one beginning with (1), (2a), (3), (4a), (5b), (6b):

III.4. Some Important Types of Sequences of Steps in Discussions

- (1) P: T_0
- (2a) Q: T_0
- (3) P: $\text{Syn}(T_0T_1) \ \& \ -\text{Syn}(T_0T_2)$
- (4a) Q: (3)
- (5b) P: $\text{Syn}(T_0T_3) \ \& \ -\text{Syn}(T_0T_4)$
- (6b) Q: (5b)

— — —
— — —

Here, the systems of precisizations with T_0 as member are investigated. The differences between the two sequences and their combination may be illustrated thus:

«Chain sequence»

«Radiation sequence»

Combination

III.5. Misinterpretation with Weight Effects

Suppose we observe an attempt at communication that we, by means of plausible auxiliary hypotheses, can subsume under the following form:

- (1) $\text{Ass}(\text{PT}_0\text{Q})$
- (2) $\text{Ass}(\text{QT}_0\text{P})$
- (3) $\text{Ass}[\text{P}, \text{Syn}(\text{T}_0\text{P}_1\text{P}(1)) \& \text{-Syn}(\text{T}_0\text{T}_2\text{P}(1)), \text{Q}] \& \text{Pr}(\text{T}_1\text{T}_0\text{P}(1)) \& \text{Pr}(\text{T}_2\text{T}_0\text{P}(1))$
- (4) $\text{Ass}[\text{Q}, \text{-Syn}(\text{T}_0\text{T}_1\text{Q}(2)) \& \text{Syn}(\text{T}_0\text{T}_2\text{Q}(2)), \text{P}] \& \text{Pr}(\text{T}_1\text{T}_0\text{Q}(2)) \& \text{Pr}(\text{T}_2\text{T}_0\text{Q}(2))$

At step (4) there is strong evidence in favor of the assumption that Q has interpreted P to have meant by T_0 something different from what P intended to convey by T_0 . There is strong evidence of *misinterpretation*. Further attempts at communication may possibly furnish evidence to the contrary, but this is irrelevant to our present *contention*, which relates to the situation at step (4). P and Q may roughly be said to explain to each other what they meant by T_0 . They thereby use two sentences, T_1 and T_2 , that seem to them to permit fewer interpretations than T_0 .

As judged on the basis of the sequence of steps (1)–(4), T_0 *has failed* as a vehicle to communicate assertions between P and Q. If P and Q use T_0 in the future, they may be expected to remember the failure and its clarification. They are apt to base the future use of T_0 on the assumptions

- $\text{Syn}(\text{T}_0\text{T}_1\text{PS}) \& \text{-Syn}(\text{T}_0\text{T}_2\text{PS})$
- $\text{Syn}(\text{T}_0\text{T}_2\text{QS}) \& \text{-Syn}(\text{T}_0\text{T}_1\text{QS})$

This may result in no more failures on the part of T_0 as a vehicle of communication *between P and Q*. The clarification has had an effect of «special prevention», but it is unlikely to have had an effect of «general prevention». If there is no strong evidence to the contrary, we shall have to expect that other persons using T_0 often may misinterpret each other as did P and Q.

Suppose the next steps in the sequence under consideration are:

(5) Ass (P-T₂Q)

(6) Ass (Q-T₁P)

In that case, the misinterpretation is of greater importance to effective communication than in the case of P and Q accepting both T₁ and T₂. We shall speak about evidence at steps (5) and (6) of *misinterpretation with weight effects*. That is, the misinterpretation represents differences in interpretation great enough to cause reversal or significant change in cognitive weight attribution. This means, again, that the misinterpretation causes pseudo-agreement or pseudodisagreement.

It is important to take possible weight effects into consideration when investigating misinterpretation, because whereas we often misinterpret each other to some extent, we do so much [less frequently] with any weight effect. Investigation of misinterpretations without weight effects may have considerable didactic or purely theoretical value but is of slight use for direct application to concrete discussions.

If P and Q have had the experience of T₀ causing misinterpretation with weight effects, there is a heavy presumption in favor of either refraining from using T₀ in discussions with a third person R, or defining it in terms of T₁ and T₂ before entering the discussion with R. If T₀ is dropped, it is natural to use either T₁ or T₂ instead.

There may, of course, be special reasons for P to expect that R in discussion with P interprets T₀ as P does, but if P does not tell R about the misinterpretation between P and Q, the use of T₀ between P and R may, even if it is successful, do much harm, since R is led to use T₀ in discussions with new persons, some of whom may use T₀ as Q does and not as P does.

Just to illustrate the theoretical development in this section, we shall give an example of a discussion that by means of plausible auxiliary hypotheses can be subsumed under the form (1)–(6), pages 150–51. The illustration is taken from an elementary course in interpretation and preciseness.

(1) P: The newspaper is thin today.

(2) Q: Yes, it certainly is.

(3) P: I mean, there is little news in the newspaper today.³

(4) Q: Oh, that is not how I understood you. I thought you meant; The newspaper has few pages today.

III. MISINTERPRETATION AND PSEUDOAGREEMENT

- (5) P: Well, I did not mean to say that. It does not express my opinion either. There are plenty of pages.
- (6) Q: But how can you say there is little news? I think there is plenty of it.

At step (2) there is verbal agreement between P and Q. At step (4) there is strong evidence of misinterpretation on the part of Q. At step (5) the evidence of misinterpretation on the part of Q increases: the sentence that Q used to indicate his interpretation is a sentence that also for P is heteronymous with the original sentence. Further, at step (5) there is evidence that P does not have the opinion that Q intended to affirm at step (2). At step (2) there was misinterpretation with weight effect. At step (6) there is evidence that Q does not entertain the opinion that P intended to assert at step (1). The misinterpretation has had a double weight effect.

III.6. Concepts of Preciseness Based on Frequency and Gravity of Misinterpretations

The main object of precization being to decrease the chance of misinterpretation with weight effects, it may be fruitful to construct concepts of precization other than those introduced, namely concepts deliberately based on criteria of actually observed cases of such misinterpretation. If the misinterpretation is defined in terms of a relation of T_0 to a pair of formulations T_1 and T_2 (the «*discrimination*»), this pair functions to clear up the misunderstanding, and we may also call them «*clarifiers*». We may, for example, introduce the following concept:

« T_1 is more discriminating than T_0 within a discussional field S » shall in this work mean the same as «There have been cases of discussions within S in which T_1 has had the function of a clarifier in relation to a misinterpretation of T_0 , but there have been no cases of discussions within S in which T_0 has had the function of a clarifier in relation to a misinterpretation of T_1 ».

The main difference between our previous concepts of preciseness and this concept is that the formulation « T_1 is more discriminating than T_0 » expresses an account of actual development of certain kinds of discussions, namely those containing elements identifiable with steps (1)–(5), or a closely similar sequence of steps. It is a historical hypothesis, an account of

III.7. «Mere Questions of Terminology»

past instances of usage, and a description of certain kinds of happenings involving past usage. Preciseness as defined by (1) on page 62 refers, on the other hand, to *dispositions* to use T_0 in certain ways insofar as possible future cases of use of T_0 are relevant. Future cases are by definition relevant as seen from (1) on page 57: «the expression «a» is a synonymic alternative of the expression «b» shall mean the same as «a» and «b» *may* be synonymous».

In the example of section 5 pages 150–52, the use of certain synonymic alternatives for the original sentence changed the discussion and revealed pseudoagreement. In that example, the formulations T_1 (The newspaper has few pages today) and T_2 (There is little news in the newspaper today) are both discriminators and clarifiers in relation to T_0 (The newspaper is thin today) within the discussion observed. If we declare T_1 and T_2 to be more discriminatory, this is a hypothesis that we, from general considerations and previous experiences, may have more or less reason to affirm. The affirmation of such a relation of discrimination may be made a broad or narrow working hypothesis according to how we delimit the discussion field S.

III.7. «Mere Questions of Terminology»

What is meant when a question is said to be «merely terminological»? Often, this saying is based on the argument that the answer to the question depends on the meaning of the question. Differences in meaning of the question result in differences in answer.

Such an argumentation holds good for any question whatsoever. If the question is interpreted before being answered, the answer depends at least in part on what is meant. Thus, in a sense, all questions are «terminological».

More plausible interpretations of « T_0 ? is a mere question of terminology» are perhaps found in the following direction of precization: «Whether one adheres to this or that answer to T_0 ? depends *only* on how T_0 ? is interpreted. Given a certain interpretation T_i ?, all agree.» In some cases a question T_0 ? seems to be called «merely terminological» if verbal disagreements among answers always represent pseudodisagreements. The expression refers to existing verbal disagreements, not to any possible disagreement whatsoever. The possibilities of interpretation are not viewed as unlimited, but as limited to certain directions that are represented in current discussion.

If this usage is adopted, the classification of questions into terminolog-

III. MISINTERPRETATION AND PSEUDOAGREEMENT

ical and nonterminological becomes largely arbitrary. It will depend on the range of interpretations considered «possible» in a rather indefinite way. It seems that besides frequency there are other factors determining the classification of what is «possible» in the realm of interpretation: the prestige and authority of the interpreters, the practical consequences of adopting this rather than that terminology, and so on.

In discussions, the answer «It is a question of terminology» to an opponent's question seems often to function as a convenient preface to an effort of precization and subsequent answer by conditional sentences: «If by T_0 is meant T_1 , then my answer to T_0 is positive. If, however, ---.»

Concluding, we may say that questions are always terminological in a certain (rather unfruitful) sense, but in other senses are only rarely merely terminological. Elaboration of the issue leads to the use of distinctions such as those of previous sections. They are able to clarify the rather obscure but important complications of communication involving «terminological issues».

III.8. Misinterpretation and Pseudoagreement in Relation to Imperatives

To the assertion of formulations correspond announcement of imperatives and posing of questions. Verbal agreement and disagreement about formulations do not correspond closely to the announcement of imperatives that are symbolized as follows:

- (1) Ann ($PT_0!Q$)
- (2a) Ann ($PT_0!Q$)
- (2b) Ann ($P-T_0!Q$)

If P uses an imperative, for example, «Q, stick to your definitions!», this may be done with Q as the only receiver of the communication or with a large public as anticipated, if not intended, receivers. To avoid confusion, we shall have to distinguish the *group of receivers* of a sentence expressing a command or exhortation (an «imperative» in the terminology of chapter 2, section 14), and the group of persons, if any, that the announcer of the sentence intends to command or exhort. We shall call the latter the *group of intended obeyers*.

III.8. Misinterpretation and Pseudoagreement in Relation to Imperatives

Even if it is essential for the purposes of an announcement that it be heard or read by people other than the intended obeyers, the announcement may be said to be directed only to the intended obeyers.

The intention does not, any more than in the case of assertions, imply honesty: we may intend to assert a falsehood, and we may direct a command to a person without the purpose of making him obey (and without pretending that the imperative is justified). If a person announces an imperative and shows the usual behavior that is connected with the delimitation of a group of intended obeyers, that group shall, in our terminology, be said to be the intended obeyers, even if the person does not wish to make the group obey. A better word for «intended obeyers» might therefore be «the group commanded or exhorted».

A command or exhortation may or may not elicit a verbal answer. If I say «Shut the door!», the intended obeyer may shut the door (or leave it open) without a word of comment. But he may also happen to *say* «Yes» or by other words or gestures *assent* to the command. We shall presume that the assent may be expressed by the sentence «I intend to obey the command (or exhortation)». If $T_0!$ is the command and Q is the intended obeyer, it will be symbolized by

Ass (Q, Sat ($QT_0!$), P)

Q asserts that Q intends to satisfy $T_0!$ with P as the intended receiver (of this message).

In the case of requests that involve complicated or time-consuming actions, it is common, explicitly and verbally, to assert or oppose the request.

Suppose we observe the following sequence of attempts at communication:

- (1) Ann ($PT_0!Q$)
- (2a) Ass (Q, Sat ($QT_0!$), P)
- (2b) Ass (Q, -Sat ($QT_0!$), P)

We shall at step (2) below speak of *verbal agreement* or *verbal disagreement* concerning the imperative $T_0!$ between P as announcer and Q as intended obeyer.

III. MISINTERPRETATION AND PSEUDOAGREEMENT

Let us, in analogy with steps (3a) and (3b), of section 3, suppose the sequence develops as follows:

(3a) Ass [P, Syn (T₀! T₁! P(i)), Q]

(3b) Ass [P, Syn (T₀!T₁!P(i)) & -Syn(T₀!T₂!P(i)), Q]

Further,

(4a) Q: That is how I interpreted you.

Ass [Q, Syn(T₀!P(i), T₁!Q(i)), P]

(4b) Q thought: Syn(T₀!P(i), T₂!Q(i))

(4c) Q: To me T₀!, T₁!, and T₂! mean the same.

(4d) Q: To me T₁! and T₂! mean the same, but something different from T₀!.

These and other possible developments are of importance for the understanding of effective communication involving imperatives, and we shall accordingly introduce and name a set of distinctions corresponding closely to those of section 2.

Verbal Agreement at Step (2) Between Announcer and Intended Obeyer

A1 Verbal agreement and interpersonal synonymy give
«expressed (communicated, conveyed) imperativistic
agreement».

A2 Verbal agreement and lack of interpersonal synonymy and
imperativistic agreement give:

A2.1 «pseudoexpressed imperativistic agreement».

Verbal agreement and lack of interpersonal synonymy and imperativistic disagreement give:

A2.2 «pseudoagreement».

The corresponding classification of conditions following on verbal disagreement is closely analogous to that concerning formulations. We need not discuss further steps because they all correspond to possibilities discussed in relation to formulations.

Let us, on the other hand, consider the following sequence:

- (5) $\text{Ann}(\text{PT}_0!\text{R})$
- (6a) $\text{Ann}(\text{QT}_0!\text{R})$
- (6b) $\text{Ann}(\text{Q-T}_0!\text{R})$

Here we also may speak about verbal agreement and disagreement, but now between two announcers (directing their appeals to the same persons or to groups that have at least one subgroup in common).

Here also we need distinctions corresponding to those introduced in relation to formulations. We shall limit ourselves to mentioning the distinction between possibilities following on verbal disagreement (symbols corresponding to those of section 2 are used):

- B1 $\text{Ann}(\text{PT}_0!\text{R}) \& \text{Ann}(\text{Q-T}_0!\text{R}) \& \text{Syn}(\text{T}_0!\text{PS}, \text{T}_0!\text{QS})$
«expressed imperativistic disagreement»
- B2.1 $\text{Ann}(\text{PT}_0!\text{R}) \& \text{Ann}(\text{Q-T}_0!\text{R}) \& \neg \text{Syn}(\text{T}_0!\text{PS}, \text{T}_0!\text{QS})$
 $\& \text{Ann}(\text{Q-T}_1!\text{R}) \& \text{Syn}(\text{T}_1!\text{PS}, \text{T}_1!\text{QS}) \& \text{Syn}(\text{T}_0!\text{T}_1!\text{PS})$
«pseudoexpressed imperativistic disagreement»
- B2.2 $\text{Ann}(\text{PT}_0!\text{R}) \& \text{Ann}(\text{Q-T}_0!\text{R}) \& \neg \text{Syn}(\text{T}_0!\text{PS}, \text{T}_0!\text{QS})$
 $\& \text{Ann}(\text{QT}_1!\text{R}) \& \text{Syn}(\text{T}_1!\text{PS}, \text{T}_1!\text{QS}) \& \text{Syn}(\text{T}_0!\text{T}_1!\text{PS})$
«pseudodisagreement»

III.9. Misinterpretation of Questions

Let us consider different developments of a communication beginning with a question and an answer. Let « $\text{Pos}(\text{PT}_0?Q)$ » stand for «P poses the question $\text{T}_0?$ for Q to answer».

- (1) $\text{Pos}(\text{PT}_0?Q)$
- (2a) $\text{Ass}(\text{QT}_0P)$
- (2b) $\text{Ass}(\text{Q-T}_0P)$

Q is here the person or group of persons asked, not necessarily the total group of receivers. By (2a) we symbolize a verbal positive answer; by (2b), a

III. MISINTERPRETATION AND PSEUDOAGREEMENT

negative. The symbolization is adapted only to questions that request the person asked to indicate whether he accepts or rejects a formulation. Thus, «Do you expect the United States to fight in another war within ten years?» can be subsumed under (1) if reformulated into «Do you consider T_0 tenable, if T_0 is «I expect . . .?»» A question such as «What do you think will be the biggest problem you or your family will have to face in the next few years?» cannot be subsumed, however.

As regards the possibilities of misinterpretation, a classification closely similar to that concerning formulations can be developed.

Thus, we arrive at the following distinctions in relation to communications opening with a verbal negative answer.

- B1 $\text{Pos}(PT_0?Q) \ \& \ \text{Ass}(Q-T_0P) \ \& \ \text{Syn}(T_0?PS, T_0?QS)$
 «expressed negative answer»
- B2.1 $\text{Pos}(PT_0?Q) \ \& \ \text{Ass}(Q-T_0P) \ \& \ -\text{Syn}(T_0?PS, T_0?QS)$
 $\& \ \text{Ass}(Q-T_1P) \ \& \ \text{Syn}(T_1?PS, T_1?QS) \ \& \ \text{Syn}(T_0?T_1?PS)$
 «pseudoexpressed negative answer»
- B2.2 $\text{Pos}(PT_0?Q) \ \& \ \text{Ass}(Q-T_0P) \ \& \ -\text{Syn}(T_0?PS, T_0?QS)$
 $\& \ \text{Ass}(QT_1P) \ \& \ \text{Syn}(T_1?PS, T_1?QS) \ \& \ \text{Syn}(T_0?T_1?PS)$
 «pseudonegative answer»

Let us then consider other types of questions and answers:

- (1) P: $T_0?$
 (2c) Q: U.
 (3) P: By $T_0?$ I meant $T_1?$, not $T_2?$.
 (4a) Q: That is how I interpreted your statement.
 (4b) Q: I thought you meant $T_2?$.

As a fifth step in relation to formulations, we took into consideration whether Q accepts T_1 and T_2 . In relation to questions, such a development makes no sense, and we do not get any corollary to the classification into pseudoagreement and propositional agreement, etc. We may limit ourselves to stressing the importance of interpersonal synonymy of question formulations.

In case (4a) we have a symptom of interpersonal synonymy of T_0 ? and hence of «real» or «to the point» answers. In case (4b) we have a symptom of interpersonal heteronymy and hence of «pseudoanswer» attributable to the difference between T_1 ? and T_2 ? as interpreted by the replier.

III.10. Latent Disagreement

In the foregoing sections, a series of concepts were introduced in order to establish a fruitful classification of steps in certain kinds of discussions. The concepts, slightly modified, are, however, applicable to a much broader field of investigation.

Let P and Q be two persons who may never have met each other and may not even know of each other's existence. Suppose they both have asserted T_0 . If, in the terminology of the analyst, P by T_0 means T_1 and not T_2 , and Q by T_0 means T_2 and not T_1 , one may still say that there is verbal agreement between P and Q concerning T_0 , meaning thereby that under certain normal conditions of communication they would react affirmatively to each other's assertion of T_0 . Let us say then that the agreement is *latent*. Similarly, «*latent pseudoagreement*» may be said to be present in cases of latent verbal agreement, lack of interpersonal synonymy, and propositional disagreement.

By such modified concepts, the potential development of controversies can be described. In practice, predictions based solely on investigations of latent relations may break down because the clash of individuals in oral or written debates introduces new factors that may influence what they say and how they interpret each other. Even if this is conceded, the latent structures are of importance, especially in opinion surveys.

Let us take an example of research in which concepts of the kind here introduced are convenient and fruitful. Tønnessen (1950–51) shows (roughly) that persons with rightist inclinations in politics accept certain favorable opinions about something they call «private enterprise». There is, in reference to certain formulations, a high degree of latent verbal agreement within the group studied. Detailed study of variations in interpretation of the term within the group shows that there are latent pseudoagreements of considerable interest. It is possible to distinguish two groups, rightist politicians and rightist businesspeople, that on the whole have different in-

III. MISINTERPRETATION AND PSEUDOAGREEMENT

terpretations of the term «private enterprise» and therefore would, in relation to certain precizations of the term, disagree. There is a relatively high degree of propositional disagreement and therefore, in relation to the latent verbal agreement, a high degree of latent pseudoagreement. By intensive use of questionnaire and interview methods, the analyst can map out the structure of latent agreements and disagreements fairly accurately and supply corrections to the usual public-opinion conclusions about agreement and disagreement. Mostly, such conclusions are based on latent verbal agreement. If 100 people answer «Yes», they are listed as agreeing. Left undiscussed, however, is what they agree to, if anything.

IV

Definitoid Statements

IV.1. Synonymity Announcement Sentences

In chapter 1 section 1, the expression «synonymity sentence» was introduced as a technical term for declarative sentences showing certain common features.

The term «*synonymity announcement sentence*» will be used for a sentence obtainable by a change in a (declarative) synonymity sentence: an expression «is», «are», «has», «have», «mean(s)», or «express(es)» is changed into «shall be», «let --- be», «is to be», «are to be», «shall have», «let --- have», «is to have», «are to have», «shall mean», «let --- mean», «is to mean», «are to mean», «shall express», or «let --- express».

As in the case of a declarative sentence, one may divide the announcement sentences into expressions indicating the *semiotic relation* («shall mean the same», «are to be used synonymously with», etc.) and expressions indicating the *relata*. Let the latter be called indications of *intended subject matter of the announcement*. They may be conveniently divided into references to, first, the expression(s) that one says shall have (etc.) the same meaning as certain others—let them be called the «*definiendum expressions*»; and second, the expression(s) that are said to have the meaning that the *definiendum expressions* should (etc.) have—let them be called the «*definiens expressions*».

The separate names suggest an important dissymmetry. If somebody says ««x is meaningful» shall mean the same as «x is testable in principle»», there is a great chance that he would not consent to the substitution of his announcement sentence with the announcement sentence ««x is testable in principle» shall mean the same as «x is meaningful»». In the case of declarative sentences, such a substitution of left-hand for right-hand

IV. DEFINITOID STATEMENTS

relatum may be expected sometimes to have no effect on the intended cognitive meaning. In the case of (declarative) synonymy sentences, a substitution of left- with right-hand relatum may, however, render the attempt at communication less adequate. If, for example, a child asks «What is democracy?» and its father answers that ««Democracy» means the same as «rule by the people»», this has perhaps a better chance of conveying something to the child than the answer ««Rule by the people» means the same as «democracy»» when the child asks «What is rule by the people?».

In addition to the definiendum and definiens expressions, the indications of intended subject matter often include *marginal references* of the kinds discussed in relation to declarative synonymy sentences.

As a convenient symbol for synonymy announcement sentences, the following will be used:

Syn (aM₁bM₂) (Ann)

The only difference from the symbol for declarative synonymy sentences is the addition «Ann» (for «announcement»). If an explicit distinction is needed, the symbol «Ass» (for «assertion») may be added in the case of declaratives:

Syn(aM₁bM₂) (Ass)

A synonymy announcement may, like a synonymy sentence, cover a vast field of occurrences or a very narrow field. It may be intrapersonal: let me mean by «true» the same as «real» (means to me). Or it may be interpersonal: for the sake of argument, let «space» mean to us the same as «space» meant to Newton. It may be intrasituational: let «moral» mean the same in our discussions as «of ethical relevancy» means in our discussions.

But as soon as it is asked, How is a synonymy announcement evaluated, tested, negated, justified?, very marked differences from declarative synonymy sentences immediately make themselves felt. Whereas the character of assertion usually associated with the latter has long been extensively discussed by those concerned with the methodology and theory of knowledge, the announcement character has chiefly been subjected to discussion in the twentieth century, and the discussion is still rather confused.

In view of this situation, it will be one of the aims of the following exposition to avoid controversial problems that are of minor importance to a fairly precise and detailed treatment of *terminological announcements* (conventions, proposals, regulations, norms).

A kind of concept that seems to us rather helpful is that of 'normative definition'. It will be introduced in what follows.

IV.2. Normative Definitions: Introduction

a. Definition

It is a wise rule not to use a designation with many and serious ambiguities as a concept designation. In certain fields of discussion, however, a term may enjoy such a dominating status that if an author takes care to avoid it, readers would hardly recognize that he deals with that field of discussion. The term «definition» is of this kind. It is in general use, and if its many senses are recognized, the designata cover considerable, and highly heterogeneous, fields of methodology.

The vagaries of this key term are far from unknown among logicians, and terms of qualification are added to it: «nominal» definition, «normative» definition, «ostensive» definition, «real» definition, and so on. Curiously enough, the complex designations are generally used as if they were expressing subconcepts or species concepts of a wide concept, that of 'definition in general'. Such a terminology amounts to a kind of rehabilitation of the term on the basis of the assumption that, after all, there must be some *important* characteristics of all concepts that have been called definitions. Justification of such an assumption, which is only too common in the case of well-established words, has not been forthcoming. Precization is confounded with specification.

In this work two concepts—or rather two concept families—will be introduced under the names of «normative definition» and «descriptive definition». A term «real definition» will also be introduced, but by means of definiens expressions that are so imprecise and difficult in application to concrete cases that we hesitate to talk about a *concept* of 'real definition'. There is no assumption whatsoever that things subsumable under normative, descriptive, or real definitions have common and specific characteris-

IV. DEFINITOID STATEMENTS

tics that warrant the introduction of a more general concept including all. In other words, the complex designations «normative definition» and «descriptive definition» are not used synonymously with «definition of the normative kind» and «definition of the descriptive kind», but rather with «normative-definition» and «descriptive-definition», suggesting single-word designations.

Very often, sentences of the kinds «Democracy is a (mere) form of government» and «A syllogism is a logical form used to test the validity of reasoning» assert, plausibly interpreted, a subsumability of an individual under a class or of a subgroup under a wider group or a subconcept under a wider concept. By *descriptive genus definition*, or in short, «genus definition», we shall mean a sentence that—according to our view as analyst—most plausibly can be interpreted in one or more of these directions. In classical logic the expression «genus proximum» has been extensively used, but the term «proximum» seems to us unfortunate if there is no established hierarchy of concepts in reference to which the genus definition is asserted.

By «*normative genus definition*» we shall mean a sentence that most plausibly can be interpreted as an announcement that an individual shall be said to belong to a class or that a subgroup (or subconcept) shall be said to be subsumable under a wider group (or concept).

These expressions will mainly be used in argumentations to the effect that certain sentences referred to by others as «definitions» are genus definitions, whereas they are mostly discussed as if they were descriptive definitions of usage, or real definitions. Confusion is likely to arise if two sentences of the form « $x_1 \in K$ » and « $x_1 \in L$ » are discussed as if they were of the form «« x_1 »syn« K »» and «« x_1 »syn« L »». The two sentences are sometimes declared to contradict each other, whereas they are more likely to be entirely compatible insofar as two different but compatible subsumability relations are being asserted.

In dictionaries and encyclopedias, it is useful to give genus definitions, but the problem of communication should be carefully considered: what is the chance that a formulation intended to furnish a genus definition, and not a complete descriptive definition of usage, will be interpreted as a genus definition by the public?

The chance can be considerably increased by careful formulation by the author of the article. The «A is B» form is usually inadequate.

If we considered groups of occurrences of the word «definition», it should be possible to construct a great number of concepts of 'definition' that would represent precisizations in relation to the total field of occurrences of «definition». Nothing like that is attempted here. The concepts introduced are held to belong to the great class of concepts that can be constructed by precisization in different directions, but it is not maintained that they are somehow outstanding among the many possibilities. It is claimed, however, that when «definition» is used for what will be introduced as 'normative definition' or 'descriptive definition', then a theory based on concepts of synonymy will be applicable.

Let us consider the following statement: «It is fundamentally wrong to identify definiendum with definiendum expressions. Real philosophical analysis gives definitions of concepts, not of expressions. That which is to be defined (for example, the definiendum) is a *concept*. Words are of interest to lexicographers, not to philosophers».

To this it may be answered that concepts are certainly interesting objects of research, but if they cannot be identified with expressions or with any other phenomena that are easily identified by different investigators by observation, we need criteria such that there is a fair degree of certainty that two investigators know when they are talking about the *same* concept and when they are talking about different concepts. One method—and the usual one in research—is to give names to concepts, that is, to specify concept designations, and to lay down the rule that this designation, if found within a certain context, is meant to name the concept at issue. The names may be perfectly conventional, for example, T, X, Puk, Punc, etc. The next step is to indicate how 'T' or 'X' is differentiated from other concepts, such that one investigator may say to another, «Aha, the concept 'Punc' that you have written about is just the same as the concept 'T' that I have been investigating». Now, such a characterization of the concept is highly difficult to give.

Suppose it happened that a person had a definite concept in mind, and had found out things about it, without ever having used a *verbal* characterization that, to him, furnished the criteria whereby the concept was distinguished from others. Now, if a person somehow has had a definite concept in mind, it is the job of the analyst to find definiens formulations that are apt to *express* the concept *named* by means of the definiendum expression «X», «T», «Punc», or «Truth», or whatever expression is selected as con-

IV. DEFINITOID STATEMENTS

cept designation. The attention of the analyst is concentrated on the definiendum only insofar as it is a *concept*-designation. What is to be defined may be said to be the definiendum *expression* only insofar as that expression functions to name a concept. That is, it is proper to say that the concept 'a' is defined by means of «b», if «a» is the definiendum expression and «b» the definiens expression.

If a philosopher has found out a great many things about 'a', the sentences may conveniently be divided into, first, those that seek to give the definitional (conceptual) characteristics of 'a', that is, give a characterization that makes us know which concept he is talking about; and second, sentences that express things he *has not stipulated but has found out* about 'a'. The first kind of sentence will furnish definiens expressions («b») in a normative definition setting forth what the philosopher has decided to talk about and to label «a». The other sentences of the book are synthetic assertions about the concept 'a', including such assertions as the one that 'a' is what Spinoza expresses by the term «*veritas*» (at certain text places), or that 'a' is such that it represents a symmetric and transitive relation between two entities, and so on.

One may thus safely say that elementary analysis is concerned with concepts. Concepts are not at all neglected. But drastic efforts are made to link hazy speculations to observable phenomena such that there is a chance of delimiting fairly definite intersubjectively constant objects of research. It is not our aim to rule out some realms of research, but to give methods for their delimitation. This makes it of paramount importance to avoid hypotheses about concepts that cannot be tested by hypotheses about sentences and designations or other kinds of directly testable assertions.

b. 'Normative Definition' Introduced

(1) In the present work, «sentence expressing a normative definition», or in short, «*normative definition*», shall be used synonymously with «sentence that announces that a certain expression within a certain field shall be interpreted or used synonymously with a certain other expression».

Let the first-mentioned expression be called the *definiendum expression*, the second, the *definiens expression*, and the field, the *intended field of application*.

Formulation (1) is insufficiently precise. Some comments and interpretations will be added that are given normative definitional status. They will, in other words, explain more accurately what (1) is intended to express.

1. Suppose a_1 is an occurrence of a definiendum sentence «a». The occurrence a_1 will be said to be used or interpreted synonymously with an occurrence b_1 of a definiens sentence «b» if, and only if, a_1 as thus used is cognitively synonymous with b_1 .

According to the general plan of exposition, a variety of concepts of synonymy are introduced later (chapter 7). It is at this stage found convenient to suggest in which common direction of precization of «synonymous» those concepts are located. The term «cognitively synonymous» is used in various ways, but the range of ambiguities is considered smaller than that of «synonymous», and the depth of intention with which it has been used, on the whole, greater. The convention expressed in item 1 is formulated in order to narrow down the ambiguities of (1) to some degree—it is adapted to the use we shall make of (1) in expositions of analysis of «definioid statements»¹ and in analysis of metaoccurrences in general.

2. Suppose a_1 is an occurrence of a definiendum designation «a». The occurrence a_1 will be said to be used or interpreted synonymously with an occurrence b_1 of a definiens designation «b» if, and only if, a_1 is used in such a way that if we, in the declarative sentence in which b_1 is presumed to occur, substitute «b» for «a», then the new declarative sentence is cognitively synonymous with the old.
3. By «sentence that announces» is meant «sentence that by its sender is intended to announce».

This convention makes it *per definitionem* valid to say that a formulation that expresses a normative definition means what its author has intended it to mean. Complications arise when the sender is an institution rather than an author.

4. The application reference is a reference to a field or fields of application of the definiendum expression. There may also be a reference to how the definiens expression is to be interpreted («the» standard of interpretation). The term «intended field of validity» will be reserved for the field indicated by the definiendum and definiens ref-

IV. DEFINITOID STATEMENTS

erences taken together. The two references will be called the *marginal references* of the normative definition.

5. The marginal references may be of any kind mentioned in connection with synonymy sentences (chapter 1, sections 1 and 2). It is presumed that a field of application is intended. That field does not need to be explicitly mentioned, however.
6. «Or» is in (1), as everywhere else in this work, used for the inclusive *or*.
7. An announcement sentence will be said to announce that something shall be, if it can be said to express a decision, proposal, or command that something shall be.
8. The definiendum expression and the definiens expression may be the same. The case of marginal references also being identical is only of theoretical interest. The shorter expression «N-definition» will often be used for «normative definition».

Convenient symbols for normative definitions:

(1s)	Syn(aM ₁ bM ₂)	(Ndf)
a	definiendum expression	
b	definiens expression	
M ₁	reference to intended field of application	
M ₂	reference to stipulated interpretation of the definiens expression, for example, by means of reference to an occurrence	

Suggested reading of (1s): «a shall in M₁ be synonymous with b in M₂».

c. Identification of Normative Definitions

Normative definitions are sometimes, but not always, expressed by synonymy announcement sentences. Such sentences are, however, convenient to use for explication of normative definitions.

Comparing the ‘field of intended application’ with ‘intended subject matter’ of synonymy hypotheses and announcements we see that the for-

mer corresponds to part of the latter, namely the subject matter represented by the occurrences of one of the expressions.

Are there sentences that with a high degree of certainty can be identified as (expressions of) normative definitions? There are, but they have so far been seldom used and do not belong to the fields of discussion in which we are primarily interested. As an example of a subsumption that can be made with a high degree of certainty, that of formulation (1) in this section may be mentioned.

Far more frequent are those cases in which a sentence can plausibly be interpreted as a normative definition *or* as something closely similar. It is here contended that for many purposes it is useful to investigate whether this holds good or not. And even in cases in which the answer is «probably not», it is sometimes useful to find out what the consequences would be if the formulation were interpreted as a normative definition.

No justification of these assertions about usefulness and fruitfulness can be given at this place. On the whole, the argumentation will refer to the use of concepts similar to the above introduced in recent methodology. In discussions showing applications of the introduced concept, its merits will, we hope, become sufficiently clear.

d. Complex Normative Definitions

A synonymity announcement usually is intended to regulate a more or less considerable, more or less vaguely outlined group of expressions. As normatively defined, only one expression is the definiendum expression of a single normative definition. One may, on the other hand, abbreviate a conjunction of normative definitions into a single sentence. One may, for example, announce that «true», «*wahr*», «*vrai*», and «*sann*» should be interpreted in this or that way, thus expressing four normative definitions.

The point is of interest only because it is not uncommon for someone to announce a normative definition and mention only one definiendum expression, whereas later argumentation seems to rest on the assumption that by the one normative definition, the use of a whole, vaguely conceived, group of other but «similar» expressions in the same or another language was regulated.

Of more interest is the case of intended fields being divided into sub-

IV. DEFINITOID STATEMENTS

fields, each corresponding to a definiens expression different from the others. It may, for example, be proposed that in psychology «a» should be used synonymously with «b», whereas «a» as used in physiology should be interpreted to mean the same as «c». In general, there may be a list of intended fields of application, and a list of definiens expressions (with their specific marginal references) and a convention that in field number *i*, the definiendum expression should be used synonymously with the definiens expression number *i*.

IV.3. Interpretative Announcements

The term «interpretative announcement sentence» will be used as a name for sentences like the (declarative) interpretative sentences except that instead of the words «is», «has», «means», «signifies», «connotes», «expresses», there occur at the corresponding places in the sentences «shall be», «let be», «is to be», «shall have», «is to have», «let --- have», «shall mean», «is to mean», «let --- mean», «shall express», «let --- express», «shall signify», or «shall connote».

What has been said about references to intended subject matter of synonymy announcement sentences may be said, *mutatis mutandis*, about interpretative announcement sentences. To symbolize the latter, we will use:

Sign (aM_1b) (Ann)

Corresponding to the introduced term «normative definition», a term «normative interpretative definition» will be introduced. To remind ourselves of the main difference in their definiens expressions, we might replace the former with «normative synonymic definition».

(1) In the present work, «*normative interpretative definition*» will be used synonymously with «sentence that announces that a certain expression, the definiendum expression, shall mean the definiens, within a certain field».

Formulation (1) is considered to be insufficiently precise as a normative definition of ‘normative interpretative definition’. No precisations or comments will be added, however, because it is unlikely that a fruitful concept

can be constructed on the basis of (1). Or, stated more carefully, it is unlikely that such a concept can be of much use for the purposes of this work. The concepts of synonymy introduced in chapter 7 are such that the intended announcement of interpretative announcement sentences are well taken care of in terms of normative synonymic definitions.

There is a strong argument for the assumption that a concept of normative interpretative definition would be more fruitful than that of normative synonymic definition:

The frequency of interpretative announcement sentences in scientific literature is much greater than the frequency of synonymy announcement sentences. This may be taken as a symptom that something like an interpretative announcement is much more often intended than something like a synonymy announcement. Thus, the applicability of concepts of normative interpretative definitions would be much more extensive than that of normative synonymic definitions.

There are, however, many circumstances that weaken the strength of the above argumentation. Nothing is said in (1) about how the definiens can be identified except that an expression is used, which by the announcer of the normative definition is intended to signify the definiens. The definiens is an inferred entity from the standpoint of the public (the receiver). In practice, a normative interpretative definition can be satisfactory only if the receiver is capable of making a reliable hypothesis about what the definiens expression is intended to signify (mean), or if he is capable of immediately interpreting the expression in a way adequately rendered explicit by such a hypothesis.

Interpretative announcement sentences often—and especially often in the exact sciences—rather obviously are meant implicitly to express an announcement with a marginal reference attached to the definiens expression. A sentence such as «*a*» shall mean «*b*» can in such cases be transformed into «*a*» shall mean *b*, «*b*» being interpreted in accordance with the introduced normative definition of «*b*» (or terms included in «*b*»). In cases of basic terms, however, no regulations have been adopted regarding how to interpret «*b*». The presence of a tacitly assumed marginal reference of «*b*» makes it appropriate to use a synonymic announcement sentence: «*a*» shall mean the same as «*b*» in the sense stipulated by introduced normative definitions».

IV. DEFINITOID STATEMENTS

If there is no explicit standard for how «b» is to be interpreted, this seems often to owe to the assumed obviousness of how «b» should be interpreted. Or, it owes to lack of definiteness of intention. Or, considerations of economy of signs play a dominant role: interpretative sentences are shorter and easier than synonymic sentences. Thus, the motive that often makes one use an interpretative announcement sentence instead of a corresponding synonymic one, is one of expository convenience.

This is not the place for a general discussion of the relation of interpretative announcement sentences to normative definitions. Suffice it to say that the greater frequency of interpretative announcement sentences compared to synonymic ones, does not constitute a strong argument for the usefulness of the concept of normative interpretative definition.

IV.4. Normative Definitions Exemplified

Note on Normative Definitions in This Work

The present work includes a great number of normative definitions. A minority of them are expressed by synonymy announcement sentences. An example of such a sentence is that which introduces the term «synonymic alternative». It has the form ««a» shall mean the same as «b»». The reason that this form is not used in all other cases of normative definitions herein is the greater expository convenience of other forms, and sometimes the requirement of style. The intended field of application is always the text of this work. (This does not preclude the possibility that proposals for extension of the field will be made under certain conditions.)

Normative definitions in this work that are not expressed by synonymy announcement sentences are expressed by means of other phrases, such as the following: «a» will be used as a collective name for b and c; the name «a» will be given to b; let us call b «a»; if, and only if, ---, then «a» will be said to be ---.

The phrases ««a» will be used synonymously with «b»» and ««a» will be used for b» are of some theoretical interest because they may plausibly be interpreted to express a *prediction* of future or forthcoming usage, or to express an *announcement* (and thereby express a normative, synonymic, or interpretative definition), or to express the conjunction of a prediction and an

announcement. In this work, the intention is to express announcement of a decision. From such announcements by an author, we may safely assume that he has—at least when making the announcement—more or less complete confidence in the corresponding prediction, which amounts to the prediction that one shall be able or has been able to realize the intentions.

Example 1

A paper by W. K. Clifford opens as follows: «1. Let us define as follows. A point is taken *at random* on a (finite or infinite) straight line when the chance that the point lies on a finite portion of the line varies as the length of that portion» (see Smith 1929: 540).

Hypothesis: Clifford intends by the quoted passage to express a normative definition. Its definiendum expression is «The point(s) --- is (are) taken at random on the (finite or infinite) straight line ---». Its definiens expression is «The chance that the point lies on a finite portion of the line varies as the length of that portion». Its intended field of application is the paper called «On higher space».

Example 2

In Terrell and Corsellis's work on patents (1927), some patent rules are quoted. In the introductory section it is said, «In the construction [= interpretation] of these Rules ---, «Office» means the Patent Office, «Journal» means the Illustrated Official Journal (Patents)» (ibid., p. 503).

Hypothesis: The quoted passage is intended to express an announcement of what the terms «Office» and «Journal» shall mean within the text represented by the British Patent Rules of 1920.

Example 3

In the introduction to *Principia Mathematica*, one finds the sentence «A definition is a declaration that a certain newly introduced symbol or combination of symbols is to mean the same as a certain other combination of symbols of which the meaning is already known» (Russell and Whitehead 1910–13: I:11).

Hypothesis: The quoted passage is intended to express an announcement of a decision that every instance of «definition» in *Principia Mathematica* is to mean the same as «declaration that [---, etc.]».

IV. DEFINITOID STATEMENTS

This hypothesis is strongly disconfirmed by taking into account the sentence following the quoted one, «Or, of the defining combination of symbols is one which only acquires meaning when combined in a suitable manner with other symbols, what is meant is that ---».

The or-sentence indicates that two subclasses of occurrences of «definition» must be distinguished. The quoted definiens is one that is adapted to only one of the classes of occurrences.

Example 4

In the text «The descriptive definition of the concept ‘legal norm’ proposed by Hans Kelsen» written by H. Ofstad (1950b), we find on page 123 the following paragraph:

«A formulation T is an *explicatum* of a formulation U» shall signify the same as «The author of U would have accepted T as for him more precise than U if he had been aware of the possible interpretations: Y, V, W, . . . of the formulation U, which were for him intention-transcendent when U was asserted».

Interpreting in the light of the context and on the basis of other data, we infer that this paragraph is intended to express a normative synonymic definition. The definiendum expression is a declarative sentence, «The formulation T is an *explicatum* of a formulation U». We have substituted «The» for «A» in the text. Such a substitution is warranted because the normative definition of normative (synonymic) definition, (1) on page 166, is formed as a «that» sentence (in the terminology of Carnap (1947: 27). Ofstad may be said to announce that a certain sentence, «The formulation ---», shall be used synonymously with another, even if he does not announce that ««The formulation ---» shall be used synonymously with ---».

The definiens expression is a declarative sentence, «The author of U ---». The intended field of application is very probably what Ofstad (1950b: 122) calls «out analysis», and which may be identified with the text from which the quotation is drawn.

The announcement may be viewed as an announcement of a decision rather than of a proposal or command.

Example 5

In Anastasi's *Differential Psychology* (1937: 156), we find the sentence: «For reasons of convenience, as discussed above, we may arbitrarily define equal

IV.5. Conditions of Two Sentences Expressing the Same Normative Definition

practice as equal time spent in practice and express scores in terms of amount done per unit of time».

The use of the characterization «arbitrarily» makes it probable that something closely similar to a normative definition is intended. From various considerations based on reading the text, we are inclined to think that an interpretative rather than a synonymic definition is intended. No explicit mention is made of field of application, but from various sayings it may be inferred to include Anastasi's text *Differential Psychology*.

IV.5. Conditions of Two Sentences Expressing the Same Normative Definition

In methodology, sentences stating that two persons adhere to the «same definition» seem to be used in rather different senses, or at least to be applied according to different criteria in practice. Sometimes the sentence is corroborated by pointing to identical *wordings* of two normative definitions. According to the introduced terminology, a coincidence of wording may be regarded as a strong symptom of identity of announcements. The auxiliary hypothesis must be made, however, that there is interpersonal synonymy between the definiens expressions. Often, that interpersonal synonymy is openly contested. Thus, whereas proponents of different ideologies announce their adherence to the Lincoln formula as definiens expression of «democracy», it is common to find actions indicating that the outgroup does not interpret the formula as Lincoln may be supposed to have done.

In the N-definition of N-definition, (1) on page 166, a «that sentence» is used: «--- sentence that announces *that* a certain expression within a certain field shall be interpreted or used synonymously with a certain other expression». Consequently, *identity of intended meaning* of definiens is required as definitional criterion of identity of N-definitions. The requirement may be satisfied irrespective of which terms are used in the definiens formulations.

It is customary to state that two persons adhere to the «same definition» in spite of differences in definiendum expression. Some, like G. E. Moore, seem to mean by «definiendum of a definition» something expressed by designations, that is, something like concepts in the terminology adopted in this work. If one adopts Moore's terminology, the «same de-

IV. DEFINITOID STATEMENTS

finition» may of course be expressed by use of very different definiendum expressions.

Even if the terminology making definiendum into concepts is not adopted, variation of definiendum expressions is tolerated. Standard translations into different languages are considered irrelevant. Thus, one may say that Einstein defines «*simultanéité*» in this or that way, even if the text of Einstein referred to is not written in French, and even if Einstein cannot in strictness be said to use any substantive as definiendum expression. In the present text, I sometimes refer to the normative definition of «preciseness». The definiendum expression is, however, «more precise than», or to be more accurate, ««a» is more precise than «b»».

According to (1), on page 166, a definiendum is a certain expression, and in our terminology, expressions consisting of different words, or words in a different order, are not identical. Thus, normative definitions may be distinguished from each other if definiendum expressions are different. Identity of two normative definitions would accordingly require identity of definiendum in the shape of identical definiendum expressions.

There are strong reasons to adopt such a requirement at least in principle.

Suppose a person interested in questionnaires asks, «How did you decide to use the expression «false»? Give me your N-definition». If I answer by saying, «I have decided to use the expression «*falsk*» (Norwegian for 'false') as follows: ---», this naturally raises the question of the adequacy of the translation of «false» into the Norwegian «*falsk*». For many purposes this translation is not adequate, but suppose we find at time S that it is, and that two N-definitions accordingly are accepted as standards. Now, if at the later moment S₁ there are symptoms of conflicting Norwegian and English theorems, involving the N-defined expressions, we may be inclined to believe that we have, after all, not used N-definitions with compatible consequences. The term «*falsk*» may after all be a bad translation of «false». The answer to the original question of how I have decided to use «false» proves misleading. If the N-definition of the expression «false» is N-defined in such a way that the expression «false», and no other expression, must occur as definiendum in all versions of the same N-definition of «false», then we are able better to distinguish different sources of disagreement. We can say, If «sameness of definition» is a hypothesis of the difficult kind relying on translation of the definiendum, the verbal or termino-

IV.5. Conditions of Two Sentences Expressing the Same Normative Definition

logical components of disagreement are more apt to be confused with other sources of disagreement.

The requirement of verbal identity of definiendum expressions is, as mentioned, important to make in principle. In practice, *explicit* recognition of the requirement in all its rigor results in cumbersome and complicated wordings. In this work we shall occasionally speak of groups of normative definitions *as if* they were identical. It is often found reasonable to suppose that if a person adheres to one, he would adhere to all, if suitable situations requiring reformulations were encountered. A person giving a normative definition of «gleich-zeitig» may be expected to decide on an identical definiens of «gleich-zeitig» and «samtidig». This makes it convenient to speak as if he had already accepted a group of N-definitions, one for each language.

Traditional depreciation of explicit marginal references has resulted in two persons' normative definitions being viewed as identical without consideration of possible, or even explicitly stated, difference in intended field of application. The researcher who N-defines his terms in the way he considers most fruitful within his particular field is often criticized by reference to fields in which the terminology might not be fruitful. What is criticized in such cases is not a proposed terminology, but a terminology derived from the first by neglecting its marginal references.

According to (1), page 166, the normative definitions of two persons are not identical if the marginal references do not express the same. Interpersonal synonymity relations are implied. At this point, as in relation to previously mentioned requirements, hypotheses about sameness of normative definitions involve complicated auxiliary hypotheses.

The character of announcement that, *per definitionem*,² attaches to normative definitions is something highly controversial in its nature, and I have not attempted to N-define it in this work. It is clear, however, that kinds of announcements have differences relevant to decisions about whether two sentences express the same normative definition. If one person announces a proposal, another a decision, and a third a command, it is an open question whether it is still fruitful to talk about one and the same normative definition being announced, even if definiendum, definiens, and marginal references are identical.

In order to take up perplexing main problems one at a time, I have so

IV. DEFINITOID STATEMENTS

far left unprecized the key expression of the adopted N-definition of N-definition, «synonymous», except for saying that it shall mean the same as «cognitively synonymous». Highly important differences of interpretation can be given to the latter term. It is not fruitful to treat two sentences as if they announced the same normative definition when there are reasons to suspect that different concepts of synonymy are implied, and therefore different criteria of N-definitions «being followed» are implicitly decided on.

In chapter 2, section 14, we introduced the technical terms «synonymy of imperatives», «preciseness of imperatives», and so forth. Normative definitions sometimes have the form of commands or requests, and the introduced terms therefore apply to them.

According to (1), page 166, two sentences expressing normative definitions in the form of imperatives are synonymous for P in S if, and only if, every expression that, according to P in S, designates a satisfaction (or non-satisfaction) of the first also designates a satisfaction (or nonsatisfaction) of the second, and vice versa.

That is, if P in S imagines possible states of affairs in relation to which he would conceive the normative definitions to have been followed, he would be unable to conceive any state of affairs such that, if it were realized, he would proclaim the one normative definition to have been followed and the other not to have been followed, and vice versa. If, in relation to every possible occurrence of definiendum, those occurrences that represent adherence to (or violation of) the one normative definition also represent adherence to (or violation of) the other, and vice versa, then the imperatives express synonymous normative definitions.

If the introduced criteria of sameness of normative definitions are used, sentences expressing the same normative definitions will, if imperatives, express synonymous imperatives, and vice versa.

IV.6. Purpose of Normative Definitions

Generally, a decision to do something has the function of eliciting reactions that without the decision would not have been carried out. A decision may, however, also function to *reinforce dispositions* to certain reaction patterns or habits, which might go on as usual even without a decision. The decision may in such cases serve to strengthen the disposition, to

make undesired variations less likely to occur, and to obtain other advantages connected with verbalized behavior as auxiliary stimuli for complex behavior patterns. Among these advantages the possibility of communication to oneself and others must be rated as an important advantage, even if it is partially a means for the already mentioned advantage of reinforcement of habits.

Generally, a decision to use «b» for «a» is apt to strengthen an already existent habit of using or interpreting «a» and «b» as synonyms, or to modify habits implying -Syn(abPS), or the decision will function to integrate a new sign «a» into the system of signs used by the person.

A terminological convention may be viewed as interpersonal decisions, intended to be identical in content. This presupposes rather complicated interpersonal synonymities.

As regards the *motives or reasons justifying* a decision to modify existing synonymy habits, we shall remind the reader of some prominent kinds:

1. Elimination of types of occurrences of «a» that have caused or are believed to cause misinterpretation of practical significance. A decision to use «b» for «a» is believed to change the interpretation of the occurrences in such a way that the misinterpretation will not ensue. Or, «a» will, if the decision is carried out, not occur in the situations in which those misinterpretations were likely to ensue.

2. Increase of *definiteness of intention* in use of «a», an increase believed to be necessary for some purpose or other. If «b» is a strong precization of «a», and it goes beyond the habitual definiteness of intention, the decision is apt to serve this end.

3. Simplification and standardization of language habits by making the existent system of synonymy and heteronymy relations less complicated.

To some degree, simplification and standardization are an important instrument for realizing the object of item 1, elimination of sources of misinterpretation. Apart from this, however, they also serve efficiency of communication and «economy of thought» in other ways.

As a schematical example, we shall describe how a normative definition functions to simplify and standardize language habits by decreasing the variability of meaning in relation to variation of person or situation, for example, by elimination of ambiguities in the sense adopted in chapter 1 of this work.

IV. DEFINITOID STATEMENTS

On the whole, the smooth operation of language habits is apt to be disturbed if a formulation «a» expresses different assertions in different situations or in relation to different persons within the same language society. Characteristics of the situations and persons have to be reacted to in addition to other characteristics. If «a» sometimes, but not always, expresses the same assertion, the bond between «a» and the organic and behavioral state supposed to be present when a person intends to make the assertion, has to be counteracted in a more or less complicated manner. If, now, there are available other formulations, which are not excessively long or in other respects as formulations inferior to «a», and which express those assertions that «a» expresses, without variations, it is convenient to eliminate «a» from use or to decide that it should always be synonymous with one of the formulations mentioned.

How such a process of simplification works in detail may be illustrated as follows:

Suppose it is found that

$$(1) \text{Syn}(aP_1S_1, aP_1S_2)$$

does not hold, and that S_1 and S_2 are types of situations likely to occur in the future. (This does not imply that misunderstandings ever occur.) That the synonymity relation (1) does not hold is usually taken for granted, if we find a «b» that is presumed to satisfy the requirement

$$(2) \text{Syn}(bP_1S_1, bP_1S_2)$$

and in relation to which «a» is variable:

$$(3) \text{Syn}(abP_1S_1) \ \& \ -\text{Syn}(abP_1S_2)$$

The decision (4) is apt to restore the desired relation (1) to postdecisional cases of S_1 and S_2 ; let us call them S_1' and S_2' :

$$(4) \text{Syn}(aP_1S_2', bP_1S_1') \quad (\text{Ann})$$

The decision, if carried out, results in:

$$(5) \text{Syn}(aP_1S_1', aP_1S_2') \& \text{Syn}(abP_1S_1') \& \text{Syn}(abP_1S_2')$$

This state of affairs implies a simplification and standardization compared with that described by (3).

We could also realize (1) by saying that «a» should be synonymous with «b» in neither S_1 nor S_2 . But then we must know a formulation «c» with the following properties:

$$\text{Syn}(acP_1S_2) \& \text{Syn}(cP_1S_1, cP_1S_2)$$

In that case we can announce:

$$(6) \text{Syn}(aP_1S_1', cP_1S_2') \quad (\text{Ann})$$

$$\text{or } \text{Syn}(aP_1S_1', cP_1S_1') \quad (\text{Ann})$$

Similarly, it is valuable for communication and economy of thought that we have interpersonal synonymities expressed by one and the same formulation:

$$(7) \text{Syn}(aP_1S_1), aP_2S_1)$$

That this interpersonal synonymity relation does not hold is usually (believed) discovered by finding a «b» that is presumed to satisfy the requirement

$$(8) \text{Syn}(bP_1S_1, bP_2S_1)$$

and in relation to which «a» is ambiguous:

$$\text{Syn}(abP_1S_1) \& \neg \text{Syn}(abP_2S_1)$$

A decision

$$\text{Syn}(aP_1S_1', bP_2S_1') \quad (\text{Ann})$$

results, if carried out, in the desired state of affairs:

IV. DEFINITOID STATEMENTS

$$(9) \text{Syn}(aP_1S_1', aP_2S_1') \& \text{Syn}(abP_1S_1') \& \text{Syn}(abP_2S_1')$$

We may now continue the enumeration of motives or reasons that are considered to justify an attempt to modify existent synonymy habits.

4. Some formulations or designations are deeply and widely integrated in the language habits of a group as expressions of important, well-confirmed assertions or well-serving concepts. To rescue these from a future status of expressing disconfirmed, abandoned assertions, or unfruitful concepts, one may propose changes in the meaning of a concept designation whenever disconfirming instances occur. The change is carried out in such a way that the deeply and widely integrated expression can be maintained with, however, slightly new meanings.

Depredation in their status of confirmation is apt to happen to all hypotheses and concepts as a consequence of continued research. Thus, important physical and chemical formulations traditionally said to express certain definite laws of nature are from time to time redefined to make it possible to retain the formulations.

The rescue is effected simply by modifying the meaning of the formulations or designations in such a way that previous disconfirmations become irrelevant toward, or confirm, the new assertions. How such modifications affect the system of hypotheses in physics and how they have inspired varieties of «conventionalism» in the methodology of that discipline have been extensively studied. There is no reason for us to go into those problems.

It should be noted, however, that decisions to change meanings by normative definitions do not in any way influence the previous disconfirmations. There is no reason to speak of immunity to disconfirmation being reached by conventions. The old assertion has been disconfirmed and is still exposed to further disconfirmation. The new is not yet disconfirmed, but may at any moment prove untenable. None of them is immune to confirmation or disconfirmation. Formulations and designations are made immune, not assertions. It is in the interest of economy of signs (of sign tokens) to change a limited number of synonymy relations rather than to change innumerable formulations that otherwise would have to be modified, and to give up designations that may appear hundreds of times in the textbooks of a certain field.

The stream of discoveries within each department of science makes any system of concepts grow more or less unadapted and less fruitful. The concepts are then «changed» more or less, that is, replaced by other concepts, often with only slightly different definitional characteristics. It is in the interest of economy of signs, as well as that of preserving what is still useful of the old language and research habits, to continue using the old conceptual designations, but to modify their meaning by normative definitions. We assume that no detailed examples are needed. A number of instructive ones are developed in elementary textbooks on methodology («acid», «atom», «chemical elements», «metal», «number», «species», etc.).

As regards designations that are new in a certain field, or are absolute neologisms, motives similar to those mentioned may be present. If great modifications, or small but very influential ones, are necessary to make a concept up-to-date, the preservation of its conceptual designation may be misleading and, no short designation being found by a combination of expressions in use, a new one is coined.

5. Very often, new designations are introduced mainly for the purpose of abbreviation: instead of using a long designation, we introduce a short one by a normative definition announcing the synonymy between them.

Suppose that there is a demand for using a designation, «b», ten times in a text of one thousand words, and suppose that «b» consists of twenty-one words. If an expression «a» consisting of one word is introduced and by normative definition said to be synonymous with «b» within the text, there will be a reduction of two hundred words. The new draft of the text will then be 20 percent shorter. Even if the time required to read the text and sufficiently understand it might not decrease as much, one may still expect a significant gain. We emphasize this trivial, numerical example because many questions of terminology could profitably be reduced to simple questions of psychology of reading and economy of time.

In this work we need a concept of 'more precise than' a considerable number of times. Each time the definiendum expression ««a» is more precise than «b»» is used instead of the definiens expression, the text is reduced by thirty-two words, if (1) on page 62 is used as the definitional formulation of «more precise than».

Whether it is justifiable to introduce a new sign is primarily a question of the psychology and sociology of reading and listening. In the

IV. DEFINITOID STATEMENTS

crowded scientific journals, sign-economical considerations tend to grow in importance.

IV.7. Preciseness of Definiendum and Definiens in Normative Definitions

It is often said that «definitions must be unambiguous». Such statements have a tendency to blur important distinctions and qualifications.

From the N-definition of N-definition, it cannot be inferred that a definiens expression must be more precise than the definiendum to anybody in any situation. This holds good before as well as after the time of announcement of the normative definition.

The hypothesis of greater preciseness of definiens expressions does not hold even sufficiently frequently to justify its adoption as a synthetic theorem of a hypothetico-deductive system.

There are, on the other hand, important connections between preciseness relations and relations within normative definitions, but of a slightly more complicated nature than the one suggested above.

1. Suppose «a» is a neologism and we plan for it to serve as a synonym for «b». To that purpose a normative definition of the decision variety is produced at the time S_1 . Is «a» more or less precise than «b» before S_1 ? If «a» is a strict neologism, it may happen that nobody would interpret it before S_1 ; for example, «a» has *no* synonymic alternatives, not even itself. From this does not follow that it must be at least as precise as any other formulation, and more precise than any formulation susceptible to synonymic alternatives. This does not follow because, according to (1) on page 62, the more precise term or sentence must admit at least one synonymic alternative other than itself.

From S_1 onward, it is to be expected that «a» turns out to be equally or less precise than «b», since any ambiguities of «b» will tend to be transferred to «a». On the other hand, the people using or interpreting «a» may occasionally forget its N-definition and make slight variations in interpretation. Within a short time there will be a tendency toward incomparability of preciseness if the comparison is not made in relation to reference classes and small groups of individuals and situations.

2. Let us next suppose that the normative definition serves the readapta-

IV.7. *Preciseness of Definiendum and Definiens in Normative Definitions*

tion of a conceptual system by means of rescuing disconfirmed formulations. In these cases it is irrelevant what level of preciseness the definiendum expression had before the announcement of the normative definition. After the announcement, however, it is to be expected that the definiens expression will not be less precise than the definiendum expression. Any relation of preciseness may turn up. It is not of primary importance to the success of the normative definition that certain preciseness relations should be realized.

Similar reflections can be made regarding normative definitions serving to introduce abbreviations.

3. On the other hand, improved preciseness in some form or other plays an important role in constructing normative definitions that serve to simplify and standardize speech habits and conventions. The same holds true of normative definitions that serve the increase of definiteness of intention or the elimination of ambiguities.

It is inconvenient, however, to put the requirement of preciseness into the N-definition of N-definition. If the preciseness of definiens is deficient, the normative definition is more or less bad, but still a normative definition according to our terminology. If superior preciseness were required *per definitionem*, it would be difficult to confirm that a sentence expresses a normative definition without empirical investigations of usage. After some time, a normative definition might even cease to exist because of new ambiguities resulting from new habits of speech.

As regards the preciseness required (synthetically) of normative definitions serving as mentioned, this is not a question of preciseness in general, but of preciseness in specific situations for certain persons, and in relation to more or less definite reference systems of heteronymous interpretations.

In the case of elimination of ambiguities, the normative definition must be based on hypotheses about the relative level of preciseness in relation to a definite reference class. Generally, interpersonal synonymity relations are involved. The normative definition fails if based on wrong assumptions about usage. Thus, if a definiens expression is introduced because it is believed to be unambiguous within a certain kind of situation, and it is not, the normative definition fails to fulfill its purpose. It also fails if it is not followed fairly consistently, or if usage undergoes such changes after its announcement as to make the definiens less precise in relation to the reference class at issue.

IV. DEFINITOID STATEMENTS

Hypotheses on usage outside the exact sciences and the science of law tend to be based mostly on armchair methods involving questionnaires put forth and answered by the same person. It is therefore not astonishing that «definitions» are viewed with much skepticism by many people: they seem to expect cases of *obscurum per obscurius* rather than cases of *obscuritas major per obscuritatem minorem*.

If a normative definition serves to eliminate ambiguities or to increase definiteness of intention, it usually also serves to abbreviate and simplify. Thus, if a short definiendum is introduced on the basis of a long and precise definiens, the normative definition seeks to retain both the simplicity of the definiendum and the preciseness of the definiens.

If an expression «b» is more precise than «a» for P in S, «b» is usually more complicated than «a». This holds good especially if «b» is a strong precization and S is outside the exact sciences. If it is desired that «a» always should be interpreted in the more precise sense of «b», this may justify a normative definition, which makes it possible to retain the use of the short or easy expression «a» and at the same time makes it reasonable to expect a sharp decrease in undesired interpretations. The decrease makes the definiendum «a» more precise, but instead of making a normative definition, why not simply decide (or propose or command) that «a» should not be used any longer? After we have made a heteronymous reference list in relation to which the undesired, practically significant ambiguities of «a» are shown, our decision may take the following form:

«If «a» is intended to be used as synonymous with a member of the reference class R, that member should be used instead of «a»».

In practice, such decisions probably are more frequent than normative definitions. Normative definitions are more useful if there is little hope of curtailing the use of «a», or if the members of the reference class at issue are much more complicated or «difficult» from the standpoint of the intended users and receivers.

By means of chains of normative definitions, we may increase the level of preciseness step-by-step. On the other hand, the many regulations may cause such a burden on memory, and interfere to such a degree with established habits, that it does not pay to introduce the chain, but rather to use the long and complicated expression (the definiens).

By «definitional (or stipulated) interpretation» of a normative defini-

tion or part thereof, we shall here mean an interpretation that is decided on by the sender of the normative definition. The purpose is to ensure that certain ambiguities of the formulation of the normative definition shall not be sources of misinterpretation. By definitional interpretations the sender tries to convey less ambiguously what he intends. They are, therefore, proposed precisizations of the original formulation.

Instead of writing out a complicated normative definition in full, one may proceed as follows:

First, «b» is used as definiens expression, and «a» as definiendum in a point-of-departure formulation. Then «b» or a part of «b» is made more precise, and it is decided that a definite interpretation b_1 of «b» or a part of «b» shall be used as synonymous with «b». b_1 is then called a definitional interpretation of «b». This process may be continued as far as necessary for the given purpose. Instead of writing out a normative definition in the shape of a single very complicated sentence, one uses a step-by-step procedure, which enables the reader to grasp the essential features before entering into stipulations concerning nuances of meaning.

IV.8. How Normative Definitions Are Criticized or Appraised: «True by Definition»

In this section we shall briefly discuss what kinds of arguments play a role in discussions centering on normative definitions among persons who agree that the sentences have the character of normative definitions or a closely similar character.³

Normative definitions do not directly express assertions (propositions). If I decide to use «a» for «b», the decision does not express any assertion, but we may on the basis of psychological and sociological hypotheses infer with varying degrees of certainty that I accept certain assertions.

Among these assertions we may note the following: «I have stronger reasons for deciding to use «a» for «b» than for not doing so.» However, the sentence expressing the decision is not synonymous with this assertion. I might conceivably add, «In spite of the strong reasons to make the decision, I have not made it. I decide not to use «a» for «b». On the other hand, I might issue a report that yesterday I decided to use «a» for «b», but without reason. Some obscure motive must have compelled me, or perhaps no

IV. DEFINITOID STATEMENTS

motive (?)». It is legitimate in a discussion in which I have decided to use «a» for «b» to presuppose that I have found more reason to do so than not to do so, but this does not warrant the hypothesis that I, by the decision, have meant the same as to assert the existence of any reasons to do so.

Similar reflections may be made in relation to proposals and commands. In preceding sections we have already mentioned that we presuppose by definition that the person who announces the decision that «a» should be used for «b» affirms the practical possibility of a situation in relation to which the decision is relevant. We also presuppose by definition that the person believes it practically possible to carry the decision into effect and believes he will make an effort to do so. Such convictions, however, do not imply assertions synonymous with a decision, proposal, or command.

This conclusion has a tendency to turn analytical if the words «decision», «proposal», and «command» are precized as indicated here, but they need not turn analytical for all plausible interpretations.

A normative definition cannot without grave danger of misinterpretation be said to be true, false, confirmed, disconfirmed, certain, uncertain, probable, improbable, etc., in the senses in which these words are used as cognitive weight expressions. The distinction is in general harmony with strong trends in analytical philosophy.

For reasons not described in this work, I think it is misleading to characterize normative definitions as valid or invalid in certain senses in which «ought» norms may be said to be valid («You ought to abstain from murder», for example).

The words most convenient to sum up (rather unprecisely) what speaks in favor of a normative definition seem to me to be the following: a decision to use «a» for «b» is wise, justified, well-motivated, adequately motivated, well-founded, and so on. Speaking in disfavor of a normative definition, we may say that it is unwise, arbitrary, premature, and so forth.

The arguments *pro et contra* may more specifically and precisely be expressed by formulations of the following kind: «the decision leads, if carried out, to a convenient terminology, a sign-economical terminology, a usage fairly precise and fairly well in accordance with previous usage». On the other hand, it may be criticized as unnecessarily clumsy, hair-splitting, or inconvenient.

The proposals may be judged good or bad for similar reasons. The com-

IV.8. How Normative Definitions Are Criticized or Appraised

mands may be judged justified by their results, if carried out, by the probability that they will be obeyed, and by their authority to command.

In hypothetico-deductive systems, formulations (or assertions) are sometimes said to «follow from the definitions», by which it is presumably meant that they are derivable from normative definitions. To be justifiable within the terminology here adopted, this manner of speaking must be a shorthand for the longer formulation «derivable from assertions that describe the immediate intended result of the decision, if carried out». Thus, if I decide that «a» shall be used for «b», then the sentence ««a» is strictly synonymous with «b»» describes the intended result of the decision. But it cannot be «derived», in any strictly logical sense of this word, from a decision.

A shorthand terminology is used in this work. The theorems are often said to be «derivable» from normative definitions.

What is the relation between sentences called «analytic» and the N-definitions?

From the previous characterizations it follows that *normative definitions are not analytical sentences* in any plausible interpretation of «analytic». If a decision to use «a» for «b» is *presupposed to have been carried out*, «a is b» is analytical in some plausible senses. Normative definitions create possibilities of analytical sentences, but are not themselves analytical. The distinction is of importance to the understanding of the hypothetical character of proofs that *presuppose* normative definitions to have been carried out.

Somewhat untechnically and as a starting-point precization, «the formation «a» is a b» is analytically true» can be taken as synonymous with «‘a’ is a characteristic of ‘b’, or is a conjunction of such characteristics».

If the designation «b» is N-defined in the following way:

$$\text{Syn (bP}_1\text{S}_1, \text{aP}_2\text{S}_2) \quad (\text{Ann})$$

then the sentence «a is a b» is *according to the decision* synonymous with «a is an a» or «b is a b», provided the requirements expressed by the symbols P_1, S_1, P_2, S_2 are satisfied. That is to say, *if* «a is a b» is used according to the decision, *then* it is synonymous with the sentences mentioned. Whether it is so used, is hypothetical. If it is, then any attempt at confirmation will be a success, if «confirmation» is N-defined in such a way that «a is an a» is confirmable. The process of testing «a is a» might conceivably (in concrete

IV. DEFINITOID STATEMENTS

cases) turn out to give disconfirmation, insofar as the confirmation is not derivable from 'a is a' and concepts of confirmation.

That a sentence or designation is used according to a decision is an (empirical) hypothesis, more or less difficult to test, and more or less likely to be confirmed or disconfirmed. In the case of highly precise mathematical language, the confirmations may be regarded as extremely strong. In the case of philosophical literature, it is different.

If we wish to give «confirm» a meaning that makes «a is a» confirmable, the confirmation will not lead to other types of observations than those of sentences expressing decisions and the interpretations of those sentences. The process of confirmation will be confined to what I shall call elementary analysis.

This is, so far as I can see, what can be said in favor of calling sentences of the type «a is a» analytically true. If they are confirmed, they are analytically true—one may say. Thus, the hypothesis that a sentence is analytically true is not itself analytically true.

Maybe ««a» is analytically true or false» could profitably be N-defined as follows: «the confirmation or disconfirmation of a requires only identification and comparison of connotations of designations or formulations contained in «a»».

The identification and comparison of connotations can be carried out only by means of hypotheses about interpretations (usage), because the connotations are probably N-defined by sentences expressing N-definitions. The various interpretations of these sentences must therefore be investigated.

The old and rather imprecise dictum that analytical sentences should have some kind of «absolute truth» or some other kind of extreme cognitive weight different from that of synthetic sentences, seems to be based on a belief in the unlimited reliability of hypotheses of elementary analysis. Sometimes investigations of what is in accordance with a decision, proposal, or command are trivial and easy; but sometimes they are not, as we shall see in later chapters.

If there are no (explicit) normative definitions covering the use of «a» and «b», the confirmation of «a is a b» must be done on the basis of hypotheses about how to interpret «a» and «b». For some plausible interpretations, «a is a b» may turn out strictly synonymous with «a is an a». When other plausible interpretations are used, this result may not follow.

If the precization «a is an a» is used, the sentence «a is a b» can be said to be analytical for at least one plausible interpretation. By this would merely be meant that, for at least one plausible interpretation, the test of the sentences is confined to identification and comparison of connotations.

IV.9. Descriptive Definitions of Usage

In chapter 1, section 2, the question was raised, What, if anything at all, is intended by synonymy sentences? Considering the variety of such sentences and the ambiguity and vagueness of their constituent words, there is no reason to expect all of them to have interesting semantic characteristics in common. In this work they are studied because they sometimes are intended to express important kinds of hypotheses about various subject matters. References, more or less explicit and painstaking, were subjected to a preliminary analysis in chapter 1, section 2. The general structure of such hypotheses about sameness of meaning has been suggested by the symbol Syn (aM_1bM_2).

A considerable number of hypotheses are referred to in technical literature as «definitions». Many of these so-called «definitions» may be plausibly interpreted to state that certain expressions mean the same as certain others. Certain other sentences called «definitions», which do not seem to have such a kind of intended meaning or which are difficult to classify, acquire a meaning of interest or an increased testability if (arbitrarily) interpreted in this way.

To remind ourselves that the structure of synonymy hypotheses is relevant to all such «definitions», we here introduce a new designation of synonymy hypotheses: «descriptive definition (of usage)». When we wish to stress that these hypotheses are (by definition) expressed by synonymy sentences, we shall use the name «descriptive synonymic definitions».

- (1) A sentence shall in this work be called a «sentence expressing a descriptive definition of usage» if, and only if, it states that a certain expression, the so-called definiendum expression, is used synonymously with a certain other expression, the so-called definiens expression, within a certain class of situations, the so-called intended field of validity of the descriptive definition of usage.

IV. DEFINITOID STATEMENTS

Some definitional interpretations and comments:

1. Definitional interpretation 1 concerning normative definitions (page 167) also applies here.
2. Interpretation 2 (page 167), *mutatis mutandis*.
3. The expression «if it states that» is used for «if it is intended to assert that or is interpreted to assert that».
4. The term «intended field of application» is reserved for the marginal reference of the definiendum. By «intended field of validity of the descriptive definition of usage» we shall mean the field that the hypothesis is intended to cover, indicated explicitly or implicitly by marginal references relating to both definiens and definiendum.
5. Interpretation 5 (page 167), *mutatis mutandis*.
6. According to (1), a descriptive definition must be a sentence. The expression «sentence» in (1) may, however, be replaced by «something».
7. In the point-of-departure formulation, it is said about the definiendum expression that it «is used» in a certain way «within a certain class of situations». If the class is a future class, «is used» must be interpreted as «will be used». Analogous changes may have to be carried out in relation to other kinds of fields at issue. The expression «is used» shall refer to *all* occurrences within the field intended. If there are subfields in which the synonymity relation is considered not to hold, a new hypothesis is formed in which the old, broad-field designation is replaced by a narrower one that does not include the disconfirming subfield.
8. The field of application may be as narrow as a single historical occurrence. As a maximum it may have no limitation. If the field is said to cover all occurrences up to the date of issue of the definition, we shall call it a *complete definition of usage*; otherwise, special. This is just another name for ‘complete synonymity’, introduced in chapter 1, page 38. If many fields are distinguished, the definition will be called complete, provided the fields together include all occurrences up to the date of issue. If different definiens expressions are listed, as in the case of complex normative definitions, but no delimitations of fields are designated or implicitly implied, then

there is no descriptive definition. This stipulation rules out most dictionary definitions.

Consider the following example. In a paper by O. Haas and G. G. Simpson (1946: 329) one reads, «In the titles of Wilson (1944, 1945) «homomorphs» obviously means «homeomorphs», as understood in the present paper».

Hypothesis: Haas and Simpson intend to give a descriptive definition of usage. Definiendum expression: «homomorphs». Intended field of application relative to definiendum: the two occurrences of «homomorphs» in the titles of two articles by A. E. Wilson, «Rafinesquina and its homomorphs Öpikina and Öpikinella» and «Strophomena and its homomorphs Trigrammaria and Microtrypa». Definiens expression: «homeomorphs». Marginal reference to definiens: all occurrences of «homeomorphs» in the article «Analysis of some phylogenetic terms.»

In the same article by Haas and Simpson it is said on page 342 that «Dacqué devoted an entire section of his book of 1935 (pp. 226–251) to «Zeitformenbildung, Zeitbaustile, Zeitsignaturen» (---), using all three of these terms indiscriminately».

Hypothesis: The last part of the quotation is by Haas and Simpson intended to express a complex descriptive definition. Definiendum expressions: «Zeitformenbildung», «Zeitbaustile», «Zeitsignaturen». Definiens expressions: the same three expressions. Intended field of validity: the text on pages 226–51 of Edgar Dacqué's *Organische Morphologie und Paläontologie*. Haas and Simpson may, according to this hypothesis, be said to assert the promiscuous synonymy of all occurrences of three terms within a certain class of occurrences.

What should by definition be meant by the formulation «The two formulations «a» and «b» express the same descriptive definition of usage (the same synonymy hypothesis)»? There is too much room for divergent interpretations to abstain from a definitional interpretation of this point. Those stipulations that have been made for criteria of identity of normative definitions (section 5) will be proposed to hold for descriptive definitions, *mutatis mutandis*.

The shorter expression «Ds-definition» will often be used for «descriptive definition» and «Ds-formulation» for «formulation of a descriptive definition».

IV. DEFINITOID STATEMENTS

IV.10. To Give Descriptive Definitions of Usage and Then to Make More Precise

In the normative definition of descriptive definitions of usage, there is no requirement as regards level of preciseness. It plays, however, a prominent role in the evaluations of descriptive definitions, a role more basic than in the case of normative definitions.

For reasons similar to those mentioned in connection with normative definitions, we find it inconvenient to put the requirement of preciseness into the N-definition of Ds-definition. We do not wish to have a normative definition that makes «Ds-definition» nearly synonymous with «good descriptive definition».

Suppose a Ds-definition

$$(1) \text{Syn}(aP_1S_1, bP_2S_2)$$

is asserted. It is asserted with a certain public as receivers. This public consists of the asserter himself, or it may, for example, be a vast and indefinite crowd of prospective readers of an elementary textbook. Let us call the asserter P_3 , the intended receiver(s) P_4 , the situation of asserting S_3 , and that of receiving S_4 . In asserting (1), the asserter normally hopes that a second hypothesis, (2), is tenable:

$$(2) \text{Syn}[\text{Syn}(aP_1S_1, bP_2S_2)P_3S_3, \text{Syn}(aP_1S_1, bP_2S_2)P_4S_4]$$

That is, he hopes, that the whole hypothesis (1) is understood in the sense intended by the asserter. Moreover, the information conveyed by (1) to the receivers is normally of interest only if what «a» expresses for P_1 in S_1 , is less known than what «b» expresses for P_2 in S_2 (or vice versa). The asserter tries to explain the sense of «a» by «b». This makes it necessary that there be agreement as regards the interpretation of «b» for P_2 in S_2 . This is a necessary condition of (2), and may be formulated thus:

$$(3) \text{Syn}(bP_2S_2, bP_3S_3) \& \text{Syn}(bP_2S_2, bP_4S_4) \\ \& \text{Syn}(bP_3S_3, bP_4S_4)$$

This condition is the basis of norms that «definiens should be unequivocal, precise, unambiguous» and so forth. These, or somewhat weaker re-

IV.11. Definitions as Condensed Characterizations (Real Definitions)

quirements, must necessarily be satisfied if (1) is to express a Ds-definition purporting to let somebody better understand what is meant by «a».

No similar requirement is necessary or desirable as regards the definiendum expression «a».

Very often, definiens in good and interesting Ds- or N-definitions is a precisization of definiendum for the announcer and for the receivers. Establishment of hypotheses as to preciseness is also usually an important preliminary to the announcements of normative definitions. On the other hand, there is no need for definiens to be more precise than definiendum in any situation or for any person. Neither normative nor Ds-definitions are in general able to fulfill the function of precisizations, nor can precisizations generally do the work of N- or Ds-definitions.

IV.11. Definitions as Condensed Characterizations (Real Definitions)

The terms «normative definition» and «descriptive definition» are designations of concepts considered to be of central importance in empirical semantics. A considerable number of sentences or assertions called «definitions» in technical literature can be fruitfully classed in terms of «normative definition» and «descriptive definition». There are, on the other hand, a considerable number of such sentences that cannot be thus handled, and that seem to have certain common characteristics of interest. They are in this section classified under the heading of «definition as condensed characterization». It does not seem possible to construct fruitful concepts that reflect the intended claim of the definitions as condensed characterizations. Very often, the sentences thus classed seem to have been produced with low definiteness of intention, or the claims made have been practically untestable.

Because of these shortcomings, the term «definition as condensed characterization» is not used to class any sentence asserting something in this work.

- (1) A formulation or system of formulations shall in this work be called a «definition as condensed characterization» if, and only if, it is intended to express a certain kind of description covering all denotata of a concept explicitly or implicitly assumed to have already been introduced. If it does not cover all denotata, but only

IV. DEFINITOID STATEMENTS

some, it will be called «too narrow». The description should be intended to satisfy the following three requirements:

1. There should be no other class of things to which exactly the same description applies.
2. Other specific or common characteristics of the denotata may be inferred (logically or in the form of well-established empirical hypotheses) from the characteristics mentioned in the description.
3. The description as a whole should be short, preferably consisting of only one sentence.

As mentioned above, the term introduced will be used to facilitate classification of sentences called «definitions» in philosophical and other technical literature.

Classifications made on the basis of the above N-definition must necessarily be rather rough because of the usual lack of information about the intentions of the authors concerned, and because of their usually rather limited level of definiteness of intention. Such sentences are also of importance to the understanding of dictionary and encyclopedia «definitions». These sentences seem mostly to function as condensed characterizations. This does not always prevent them, however, from having additional functions of a more exact character. They may, for example, suggest both an N-definition and a condensed characterization.

The designation used for the denotata will be called the *definiendum*; the description will be called the *definiens* of the definition as condensed characterization.

As another name for «definition as condensed characterization» we shall use «real definition», abbreviated as «R-definition».

IV.12. Definitions as Condensed Characterizations Exemplified

The world's patent claims compose a formidable collection of definitions as condensed characterizations. The highly developed art of both codification in this field is of both practical and theoretical interest to the theorist of interpretation. It is to be hoped that the future will bring more cooperation between patent drafters and theorists of interpretation. Preliminary contacts have convinced both groups of its fruitfulness.

The rules for describing inventions are (at least in the United States) such that they assume invention to have something called an «essence» or «a real nature». It is the real nature or the essence of the inventions that is to be described in a patent claim. This terminology may be a remnant of old textbook accounts of «definition». It has had profound effects on the practice of patent-claim drafting. According to patent law, the «definition must be equivalent or commensurate with that which is defined, it must be applicable to all the individuals included in the concept and to nothing else» (Stringham 1930: 17). That is, *given* the denotata, one must look for common and specific characteristics. But are the denotata «given», in the sense of being surveyable or observable? The quoted rule brings up a difficulty at once. It assumes that we already know all the members of the group to be defined (*ibid.*, p. 18). One has to take into account all possible denotata fabricated in the future (as long as the patent will be valid). The group of objects that is to be given a definition as condensed characterization is in the case of inventions largely unknown. The characterization will be hypothetical. What Stringham says about «definitions» holds good of real definitions (in our terminology):

The requirement of shortness applies to real definitions of inventions. A claim with about 240 words was in the Brick case characterized as «long and formidable». (*Ibid.*, p. 224)

Example 1. The following definiens formulation appears in a real definition of the nature of an invention: «[a]n incandescent electric lamp having a filament of tungsten or other refractory metal of large diameter or cross section or of concentrated form and a gas or vapor of low heat conductivity at relatively high pressure, the combination being such that the filament may be raised to a much higher temperature than is practicable in a vacuum lamp without prohibitive vaporization or deterioration or excessive shortening of useful life, substantially as set forth». The patent was, in this case, held invalid by a British court of first instance «and by the Court of Appeal on the ground that the word «large» was not sufficiently clear in its meaning to define the ambit of the monopoly ---». The House of Lords, however, «held that there was no valid objection to the claim ---» (Terrell 1927: 118).

Example 2. For a simpler example of a real definition, we may turn to the glossary in Woodruff's *Animal Biology* (1932: 473), where we find «Abio-

IV. DEFINITOID STATEMENTS

genesis. The abandoned idea that living matter may arise at the present time from non-living, without the influence of the former». The expression «abandoned» suggests that the sentence has a function more closely related to a real definition than to a normative or descriptive definition. If the expression were included in a normative definition of abiogenesis, the idea referred to could not be maintained as a hypothesis. This impossibility is scarcely intended by the author of the «definition», and it contrasts with usage. If the expression were left out, the quotation might well be classed as a descriptive definition or a description of a normative one.

Example 3. «Binomial nomenclature. The accepted scientific method of designating organisms by two Latin or Latinized words, the first indicating the genus and the other the species» (Woodruff 1932: 474). The expression «accepted scientific» is here analogous to the expression «abandoned» in the first quoted sentence, and the formulation is presumably classifiable as a real definition. If it were changed to «Method of designating --- species. The method is accepted in science», the first sentence could plausibly be interpreted as functioning partly as a description of a normative definition of the decision subclass. Woodruff scarcely tries to make a decision on terminology all by himself, but wishes to describe a decision made long ago by other biologists. He might also wish to describe the use of the expression «binomial nomenclature» in biological literature. In that case the sentence also would function as a descriptive definition.

Example 4. «Chlorophyll. The characteristic green colouring matter of plants, through which photosynthesis takes place» (ibid., p. 476). Here, «chlorophyll» is «defined» by a causal relation. It is improbable that Woodruff would call a substance «chlorophyll» that did not have approximately the same chemical structure, even if it should be discovered that this substance is the one «through which photosynthesis takes place», and not the one formerly believed. G. J. Peirce, in his *Physiology of Plants* (1926: 57), speaks of «chlorophyll pigments»—chlorophyll, carotin, and so forth. That Woodruff would not in a normative or descriptive formulation include reference to the very important function of the pigments often called chlorophyll, is suggested by the following passage: «--- the expression «green plant» does not refer specifically to the colour of a plant (---), but to the fact that there is present a complex pigment functionally similar to chlorophyll by virtue of which the plant is a constructive agent in nature».

(Woodruff 1932: 34). Especially the expression «functionally similar» suggests that Woodruff would not descriptively define «chlorophyll» by its physiological function, but as a subclass of pigments. We are for this and other reasons inclined to classify the sentence as a real formulation. Students more easily remember «the essence» of chlorophyll by means of a short, condensed sentence.

A number of short utterances about «democracy» and allied terms are probably classifiable as real definitions:

Example 5. «Das Wesen der demokratischen Verfassung ist ---, dass sie ohne Rücksicht auf gesellschaftliche Unterschiede alle Erwachsenen oder doch alle männlichen Erwachsenen zur Teilnahme und der Handhabung der öffentlichen Gewalt beruft» (Sering 1917: 42).

Example 6. «Demokratie (---) ist Identität vom Herrscher und Beherrschten, Regierenden und Regierten, Befehlenden und Gehorchenden» (Schmitt, 1965: 234).

We have defined real definitions in relation to denotata of a class rather than in relation to connotation,⁴ because some or all of the essential characteristics may be underivable from the characteristics included in the connotation. The underivable characteristics, for example, «abandoned opinion», «accepted opinion», «something through which something takes place», in the quoted examples, account for the main difference between formulations of real definitions and formulations of normative and descriptive definitions.

Just like Ds-formulations, the R-formulations express hypotheses (theories), but whereas the former are about usage, the latter may concern anything—for example, the behavior of certain kinds of organisms in certain situations.

The R-formulations are general theories about denotata; the Ds-formulations may be particular theories about usage within narrow types of situations.

An R-formulation as defined in this work is responsible for every single denotatum. If 1,000 denotata are studied and one is left out, there is a chance that it will have a character sufficiently different to warrant a change in the R-formulation. Or, one might split the connotation in two and let number 1,001 fall under a separate connotation.

In textbooks, encyclopedias, summaries, and technical glossaries, one finds numerous formulations that could be classed as R-formulations if it

IV. DEFINITOID STATEMENTS

were not probable that the authors had no pretensions of giving a definition covering *all* denotata or of giving only perfectly specific characterizations. More stress is laid on ease of understanding and on short, vivid expression. The formulations are mostly strong popularizations, which function to give preliminary and approximate knowledge.

Knowledge of denotata will always be limited, even if all of them are investigated separately. For most purposes, it is sufficient to form R-formulations on the basis of samples selected according to statistical sampling methods.

IV.13. Sentences with Complex Definitional Function

Let us consider a sentence of a kind commonly found in textbooks of the exact sciences.

(1) «A point moving with a variable velocity, relative to any frame, is said to have an acceleration relative to that frame.»

The sentence is taken from A. E. H. Love's, *Theoretical Mechanics* (1897: 33). In the preface, Love states that the «purpose of this book is didactic, it is meant to set before students an account of the principles of Mechanics, which shall be as precise as possible, and which shall be in accordance with modern ideas». The exposition is built on a small number of concepts; that of acceleration is based on that of velocity and other concepts.

From the preface and the expression «is said to» and from other sources of information, I infer that (1) is a reproduction of a sentence produced beforehand, or that Love believes that the sentence, to him and to competent readers, expresses the same as what was expressed previously by the same or by other sentences by himself or by other authors. The sentence may in that case be said to be intended to function as a description of a normative definition put forth before Love produced sentence (1). Maybe this is the sole intended function; maybe it is only one of the intended functions.

If the sole intended function of (1) is to describe a normative definition, it might be formulated as «According to the stipulations of modern terminology, a point moving with a variable velocity, relative to any frame, is said to have an acceleration relative to that frame».

In the literature antedating 1897, there are sentences in textbooks that

resemble (1) more or less. It is scarcely possible, however, to speak of one and the same concept of 'acceleration' being introduced by all authors, particularly because the concept is often based on concepts of 'velocity' and 'movement', which show rather obvious internal differences.

Why has Love selected (1) among the many possibilities? I think we can infer that whatever his motives are, the appearance of (1) to the exclusion of other possibilities indicates, among other things, that he has *decided* to use the word as indicated by (1) in *his* book, and that he expects his readers to test the statements of the book on the basis of the terminology adopted. There is no compulsion for anybody to adhere strictly to a particular usage. It is, therefore, usually of some importance for an author of textbooks to indicate which usage will be adhered to in the book at issue.

Suppose a student using Love's textbook interprets «acceleration», when it occurs later in that book, as synonymous with «positive acceleration». We cannot say that this usage is in conflict with (1), or that the student uses the term wrongly or has misconceived (1), or that he does not adhere to the introduced terminology—if (1) is solely considered to be a *description* of a particular existent usage. More correctly, we could make such reproaches under those circumstances, but not then on the basis that the student should have taken the appearance of (1) as a symptom that Love is an *advocate* of using «acceleration» in accordance with the use indicated by (1). Later occurrences of «acceleration» in Love's book seem to be in accordance with what he states «is said».

It seems contrary to scientific method to rely on guesses or inferences of the above kind, especially in mechanics, where students are trained to construct proofs in which it is crucial that terms like «acceleration» be used in fairly uniform ways in accordance with explicit decisions common to a group («conventions of terminology»).

If (1) is to function solely as a description of a particular usage, the text ought to include a normative definition, or at least a forecast of how the term «acceleration» is going to be used. Even if the normative definition in that case did not differ from previously produced normative definitions of «acceleration», it would be of importance. The text might in that case be formulated as «Most theorists of mechanics have decided to use «acceleration» in the following way: «the point, x, has an acceleration relative to the frame F» shall mean the same as «x is moving with a variable velocity

IV. DEFINITOID STATEMENTS

relative to the frame F». I have decided to use the expression in the same way».

Now, if an author wrote in this way, he would probably be considered pedantic. Why not rely on the fact that readers will take it for granted that an author by (1) *also intends* to communicate that he has decided to use the word as indicated by (1)?

As far as I can see, (1) can plausibly be interpreted as expressing *both* a description of previous use or of a previous normative definition (with the textbook as intended field of application) *and* a decision to adhere to a certain usage.

The expression «is said to» as it occurs in (1) seems occasionally to be used descriptively and with reference to the past use of others or the future use of the author; occasionally it seems to be used in a normative definition; and occasionally, I think, it can most plausibly be interpreted as expressing a combination. I guess that (1) is an instance of such a mixed function.

If we introduce uniform interpretations permitting a sentence like (1) to have mixed functions in the sense indicated, we need not guess or infer normative definitions that are important in proofs of theorems. We can in the proofs use the argument «According to the terminology decided on by (1), we can derive this --- from that ---». We need not every time say, «If we decide to use «acceleration» in the sense described in (1), then ---».

It would seem, then, that the concept of ‘sentences with mixed descriptive and decisional (or commanding) function’ is fruitful, and that many sentences can plausibly be interpreted as being intended to satisfy such a complex function. Particularly, discussions in the exact sciences seem to be based on the assumption that sentences are thus interpreted—and with success: there is little room for misconceptions.

Let us consider another example. In Shull’s textbook *Heredity* (1926: 116), we find the following passage:

(2) «*Multiple Factors*. Multiple factors are two or more pairs of genes having similar and cumulative, though not necessarily equal, effects.»

Shull himself classed the sentence as a «definition» (in a sense not explained), as is seen from the next sentence of the text, «An example that has been thoroughly worked out will make the definition clear».

The term «multiple factor» is introduced in the textbook by means of (2). In the sentence following the last citation above, a second instance of the expression occurs, «Nilsson-Ehle of Sweden found that two varieties of wheat, one having reddish-brown, the other white grains, owe their colour differences to multiple factors».

Probably very few analysts would deny that we are justified in deriving, (although even fewer would agree that we ought to make the inference) from (2) that «multiple factor» as used in the second occurrence of this expression is intended by Shull to be synonymous with «two or more pairs of genes having similar and cumulative, though not necessarily equal, effects».

What, in that case, is intended by (2)? Suppose that (2) is not an explanation of multiple factor or 'multiple factor', but rather of «multiple factor». That is, a short expression «multiple factor» is, maybe, introduced and implicitly declared to be used or to have been used synonymously with a longer one. Or perhaps a convention (group decision) is duplicated, reproduced, or described. Or a usage is predicted. Or, perhaps, the intention is to express a kind of N-definition.

More plausible interpretations besides those mentioned are found by looking for mixed functions. As examples, we might mention the following groups of sentences as possibly expressing the same as Shull intended by (2):

(2a) The expression «multiple factor» shall according to a terminological convention be used as synonymous with «two or more pairs of genes having similar and cumulative, though not necessarily equal, effects», and it is my decision to join that convention.

This formulation is a description of various decisions. Another possibility is:

(2b) The expression «multiple factor» is used as a synonym for «two or more ---, effects»; this shall also be its use in this work.

The sentence (2b) has a mixed function. It functions to express a descriptive definition of usage and to express an N-definition.

Explicitly, we shall N-define «sentence with complex definitional function» as follows.

(3) ««a» is a sentence with complex definitional function» shall in this work mean the same as «One and the same occurrence a_1 is intended to express the same as the conjunction of two or more sentences of the following kinds:

IV. DEFINITOID STATEMENTS

1. sentence expressing a normative definition;
2. sentence expressing a descriptive definition;
3. sentence expressing a real definition.»

It is open to doubt whether there exist sentences with complex definitional functions involving real definitions. If a sentence at a definite place in a text is meant, among other things, to express a descriptive definition of usage, does it occasionally happen that it also is meant to express a real definition? This is a psychological question, and not easily answered. If there are strong symptoms that a sentence has both a Ds- and an R-definitional function, we expect that there would also be symptoms of confusion and low definiteness of intention on the author's part.

IV.14. Concepts of Synonymity and Concepts of Definition

Many sentences called «definitions» or said to «express definitions» fall within the domain of synonymity hypotheses and related subjects. It has been our main object to stress this connection and to base the treatment of such sentences on the methods introduced in preceding chapters. Thus, the main purpose of this chapter has been to show how the treatment of some of the sentences called «definitions» can be covered by the system of terms suggested in chapters 1 and 2.

This purpose necessitates that those subgroups of sentences called «definitions» that fall under the domain of synonymity hypotheses of some sort, be distinguished from similar kinds. Thus, we were forced to take up normative definitions and real definitions.

As seen from (1), page 166, and from other normative definitions, the treatment of these new kinds of sentences is to a considerable degree mixed up with terms and hypotheses of the preceding chapters. This gives us an additional reason to undertake analysis of sentences occasionally called «definitions», even if they are not synonymous with synonymity hypotheses of some sort.

On the other hand, we have not tried to survey the main directions of precization of the word «definition». There are a great number of occurrences of this word that we have not felt compelled to discuss or to make the basis of any concepts.

In concluding this chapter, I should like to mention some relations between «synonymy» as used outside this work and normative definitions.

Suppose two expressions «a» and «b» are introduced by two normative definitions in which «a» and «b» function as definienda, and in which the definientia expressions and the expressions of intended field of application are identical. In such a case there is a tendency to treat «a» and «b» as synonymous. It is usually very difficult to decide whether «synonymy» is in that case used to designate a concept 'synonymy' from which it is *derivable* that «a» and «b» are synonymous if introduced by identical definientia; whether it is used to designate a concept 'synonymy' that makes it *empirically plausible or expectable* that «a» and «b» are synonymous if N-defined in the same way; or whether neither of those alternatives is realized, for example, because of lack of definiteness of intention.

If «synonymy» is used according to the first alternative, then it is irrelevant to the question of synonymy whether «a» and «b» are used as decided upon. If «a» and «b» are used very differently because the decision, command, or proposal is completely disregarded, this does not prevent «a» and «b» from being synonymous if the existence of a normative definition is enough. Such a consequence is undesirable because it would entail a great number of changes in our terminology. It is convenient for us to let the difference between followed and nonfollowed normative definitions stand out clearly in our terminology. In chapter 7, the term «N-concepts» of synonymy is used to cover the cases in which an N-definition can prove synonymy.

Of greater interest is a sufficient but not necessary criterion of synonymy introduced as follows:

- (1) If the normative definition

$$\text{Syn}(aP_iS_j, bP_mS_n) \quad (\text{Ann})$$

 is strictly followed, then

$$\text{Syn}(aP_iS_j, bP_mS_n)$$

Sentence (1) turns into a positively analytical sentence if «strictly followed» is precized operationally in such a way that the synonymy concept symbolized by Syn in the normative definition is used as the criterion of its being followed and if Syn in the last line of (1) also symbolizes that concept.

Sentence (1) turns into a synthetic theorem if a different synonymy

IV. DEFINITOID STATEMENTS

concept from that introduced in the second line is introduced in the fourth line of (1). In the following we decide that (1) should be interpreted (*per definitionem*) in such a way that only one kind of synonymy concept is used in the two symbolizations of (1).

IV.15. Predictional Theories About the Use of an Expression

Suppose «a» (for example, «democracy», «be careful!», or «it rains») is an accepted vehicle of communication between people of a certain language community, and suppose it is asked, What does «a» mean when used by the people (or a definite person) of the community? The answer that «a» means 'b', but that in fact no person of the community ever intends to express 'b' by «a», would usually be considered awkward. There is, however, important research concerning the use of «a» within the community, and it is not concerned with the *intended* meaning of expressions in use. In the terminology of some authors, the research may nevertheless concern «meaning».

One may ask, Under which conditions will a definite person or group of persons produce use instances of «a»? If «a» is a declarative sentence, one may ask, Under which circumstances will «a» be asserted (by certain persons, or generally)? Or, one may be less interested in the events of production and ask, Where can «a» be expected to be found?

This kind of question ignores questions about intended meaning. It is analogous to natural-science questions of the following kinds: Under which conditions does a thunderstorm develop? Under which conditions will oxygen and hydrogen mixed together combine and form water? Where can uranium be expected to occur? The same kind of question is asked about psychological and social phenomena: Under which conditions are revolutions likely? Under which conditions will babies react with anxiety toward dogs? It makes no essential difference methodologically whether the questions are posed about past events. One may ask, Under which conditions have babies (until now) reacted with anxiety toward dogs?

Answers are attempted in a fairly general, simple, and testable form. The crux of the matter is the possibility of understanding, predicting, and explaining the phenomena on the basis of certain units of information.

Suppose the following problem is given: under which conditions will sentences of the form «x is of national interest» be asserted by U.S. govern-

ment officials? The problem does not necessarily lead to an investigation of what such officials *intend* to express by sentences of the form «x is of national interest» (cf. Beard 1934).

What is demanded is a formula or theory such that the past occurrences of sentences of the quoted form are explained and future occurrences are successfully predicted.

Sometimes, as in the case of Beard's explanations, it is to be expected that the senders would deny—and maybe justly—that the *intended* meaning is something closely similar to the formula used as explanans⁵ expressions in proposed explanations or predictional formulas.

Many sentences that are called «definitions», or are proclaimed to state the «meaning» of terms or sentences, may plausibly be interpreted as sentences expressing *theories* about *conditions* of occurrence of expressions or classes of expressions. They will be called *predictional theories*. They will be distinguished from theories about senders' intended meanings or receivers' interpretations. The predictional theories may occasionally contain references to sentences expressing assertions about users' intentions, but need not do so.

The importance of distinguishing predictional theories from descriptive definitions about intended use lies therein; the former often are formulated as if they were identical with the latter, but they are mostly untenable thus conceived.

Voltaire may, for example, say that mankind uses the term «truth» for mistakes and illusions, and he may thereby create a furor of indignation. He possibly meant that so many opinions put forth as «truths» are mistaken, that the best way to predict occurrences of «truth» is to consider whether the opinion in question is a mistake. If it is a mistake, he predicts, it will be called a «truth». He has scarcely intended that people call something a «truth» when they *intend to convey to listeners* that they consider it a mistake.

Mussolini declared that «Démocratie, c'est le gouvernement qui donne ou cherche à donner au peuple l'illusion d'être souverain» (quoted in le Bon 1931: 291). Mussolini scarcely entertained the opinion that those using «démocratie» intended this meaning. Studying what have been called «democracies», Mussolini was, perhaps, willing to assert that the use of the term follows the regularity expressed by his definiens expression.

IV. DEFINITOID STATEMENTS

In *Twentieth Century Sociology* (Gurvitch and Moore 1946: 71), Howard Becker writes, ««[m]ysticism» to many of this gentry [positivists], simply means «not orthodox Watson behaviorism»». Maybe Becker means that what these people intend to express by the term «mysticism» is a concept 'not orthodox Watson behaviorism'. It is more likely, however, that he is constructing a theory about the conditions under which they react with the characterization «mysticism». Possibly he means that if they are confronted with something that is not orthodox Watson behaviorism (in the terminology of the analyst), they are apt to class it under the heading «mysticism».

Predictional theories about the use of a concept designation are tested primarily by analysis of those things that users point out as denotata. Thus, if a predictional theory about «truth» says that «truth» is a name for «*was dem Denken das grösste Gefühl von Kraft gibt*», then the test will be a psychological one. One would have to select a fair sample of meanings and investigate the feelings of those who apply the name. It would be necessary to lay down criteria of intensity of feeling of strength and to correlate use occurrences with the findings.

If one permits oneself to use an old, rather ambiguous phrase, the predictional theories about expressions concern the symptomatic, not symbolic, functions of signs.

In practice, hypotheses about intended meanings will largely have to be tested on the basis of regularities in use of the terms whose meanings are under discussion. These regularities are also the basis of predictional theories. Nevertheless, the two kinds of hypotheses differ. Some observations are highly relevant to the one, but not to the other, and instances of confirmation of the one may not be instances of confirmation of the other.

Elementary Analysis

A. Description of Synonymity and Ambiguity Hypotheses and of Simple Definitions

V.1. Description of Hypotheses Expressed by Synonymity and Ambiguity Sentences

As a first kind of elementary analysis, we shall consider attempts to describe hypotheses assumed to be expressed by synonymity sentences. As analysts we read synonymity sentences and, in most cases, make the tentative assumption that they were produced with assertive intent. We are sometimes interested in finding out something about what they assert, that is, what the sender intended when sending a definite instance of a synonymity sentence, what a certain synonymity sentence mostly has been intended to express, how certain receivers have interpreted the sentence and so on. To avoid looking for exact meanings where there are none, we may feel compelled to undertake an investigation of definiteness of intention.

The attempts to describe hypotheses expressed by synonymity sentences do not presuppose that the analyst has his own concept of synonymity. He investigates events, processes, and states of affairs connected with sentences in which the term «synonymity» and other terms of the synonymity sentences occur, but he need not use such terms himself. His description will probably contain the word. He is engaged in activities of interpretation, and his account will probably contain metaoccurrences, but not necessarily use occurrences, of the terms interpreted.

As a matter of fact, in chapter 7 we shall, as analysts, sometimes use expressions such as «synonymous with» and «means the same as», but with-

V. ELEMENTARY ANALYSIS

out going into details about what we mean by them. In the present chapter, however, we limit ourselves to offering rather imprecise definiens expressions: by «synonymity» between sentences we shall mean in this chapter «identity of cognitive meaning, sameness of assertive content».

A particular synonymity *sentence* may be described as one belonging to the skeletal form «--- means the same as . . .», or as containing certain marginal references, or as being written in the English language, and so on. Descriptions and quotations of synonymity sentences are not of sufficient interest to warrant detailed study.

Quite otherwise is the situation that confronts those who try to describe synonymity *hypotheses* fairly accurately. A hypothesis cannot be quoted: only the sentences supposed to express the hypothesis can be quoted. The description of the contents may, of course, be made in terms of its author, but this presupposes the validity of complicated interpersonal synonymity assumptions. Often the context of the original expression of the hypothesis is of first-rate importance.

In this chapter we are concerned with descriptions of hypotheses. The hypotheses do not assert the hypotheses described. The descriptions are, on the other hand, themselves assertions. Consider, for example, the description «Bryce makes the hypothesis that «democracy» always means the same as «the rule of the many»». The assertion intended by the analyst may be untenable, or we may find that it is ambiguous, vague, scarcely testable, and so forth. Doing this, we are engaged in activities here subsumed under the heading «elementary analysis». We are not necessarily interested in the question of whether, as Bryce asserts, «democracy» *is* synonymous with «the rule of the many», whatever that may mean.

By «description of a hypothesis», we shall mean a description of its cognitive content, not its history. The history may be of primary importance for the understanding of its contents as assertion or system of assertions, but the historical account is not what we look for.

A description of a hypothesis may not (in our terminology) be a complete description. Let us compare descriptions of hypotheses to descriptions of demands. A description of children's demand for food may be more or less complete. It may consist only of statements of the kind, «Children's demand for food is more insistent than that of octogenarians». Analogously, a description of certain synonymity hypotheses may consist merely

of the following kind of statement: «the hypothesis has a cognitive meaning such that it takes years to test it». We may say that the hypothesis Crew intends by his words «--- in the time of Newton, density and specific gravity were employed as synonymous» is such that it asserts the substitutability of the two terms in texts written during the lifetime of Newton. Or, the analyst may describe it as a hypothesis that has a content such that «x has the density y» and «x has the specific gravity y» are equipollent. Neither of these contributions to a description of Crew's hypothesis may be intended to furnish a complete description.

Descriptions of hypotheses and descriptions of demands have in common that they describe something not directly observable. Demands, needs, drives are inferred entities (constructs, intervening variables, models, fictions), just as hypotheses are. Their methodological status is highly controversial. The change from formulations of hypotheses to the hypotheses themselves (expressed by the formulation) resembles to some degree the change from talking about certain food behaviors to talking about demand for food.

If a hypothesis can be reduced to the form $p \& q$, where p expresses a synonymity hypothesis and q expresses some other kind of hypothesis, « $p \& q$ » will be said to express a hypothesis that *implies* a synonymity hypothesis. Interpretative sentences—for example, ««a» means b»—are often of that kind. If a hypothesis does not imply a synonymity hypothesis, but (in the opinion of the analyst) presupposes one to be valid, we shall say that such a hypothesis is *involved* or *assumed*.

In this chapter, not only explicit synonymity hypotheses, but also implied, involved, or assumed ones are described.

Perhaps some readers find it unjustified to devote a whole chapter to techniques of describing hypotheses that conceivably might be expressed by synonymity sentences. This critical attitude owes perhaps to an insufficiently clear distinction between sentences and what may be expressed by sentences. The distinction requires separation of a formulation of a hypothesis from the hypothesis as an assertion. Elementary analysis aims at description of hypotheses as assertions, not just as references to formulations found in texts already at hand.

Hypotheses are more or less completely formulated, and the formulations are more or less precise. If a hypothesis belongs to a system such as

theoretical physics, the whole system contributes to the meaning of its formulation. This, and requirements of communication, makes it impossible to point at a certain sentence or series of sentences and to say with reason, «*There* is the hypothesis expressed in complete detail».

In psychology a great number of names suggest hypotheses—for example, «the sign-gestalt theory of learning»—but if we ask psychologists to say just what the theory asserts, there are no standard formulations and there are considerable differences of opinion. Thus, the task of describing hypotheses is difficult in the exact as well as in the less exact sciences. Hypotheses and opinions in general are, once more, inferred entities, the existence of which cannot be «shown» except by giving reasons for or against the assumption of their existence based on observations of verbal and non-verbal behavior. Descriptions of opinions necessarily involve more or less uncertain interpretations, and good descriptions of them *generally* involve precization of the formulations traditionally used to express the opinions.

The analyst who takes up the task of distinguishing between hypotheses that do and do not involve hypotheses of synonymy, and the task of constructing fairly precise formulations of their contents, encounters a host of difficulties. These are attributable, among other things, to:

1. limited definiteness of intention by the authors of synonymy sentences; lack of attention (on the part of the producers) to assertions involving hypotheses about synonymities; lack of explanations;
2. vagueness and ambiguity of marginal references;
3. extreme shortness of expressions functioning as formulations of synonymy hypotheses (much is implicit and barely hinted at);
4. extreme variability of terminology and richness of near-synonyms among the expressions of such hypotheses;
5. tendency to overlook auxiliary hypotheses necessary to subsume any hypothesis under the heading «hypothesis of synonymy»;
6. absence of independence between these and other factors, which often act together and create an almost inexhaustible complexity of texture.

Let us consider some examples of sentences that, for some plausible interpretations, express or involve descriptions of synonymy hypotheses or announcements.

Haas and Simpson (1946: 333) state in their painstaking elementary analysis of certain biological terms that «Bourne --- considers parallelism a mere synonym of homoplasy ---». The analysts, Haas and Simpson, describe something that they probably intend to be a hypothesis adhered to by Bourne. The hypothesis is expressed in the vocabulary of the analysts; Bourne is not quoted. Possibly Haas and Simpson intend to describe a synonymity hypothesis.

In the same paper, Haas and Simpson state that «--- Buckman ---, in discussing parallelism and homeomorphy, defines the former as «the tendency of different genetic stocks to pass, quite independently, through similar phases of development»» (ibid., p. 326). Here, a definiens expression is simply quoted, but the semiotic relation is indicated in terms used (not quoted) by the analysts, that is, by Haas and Simpson. The terms used by the analysts to convey to readers the kind of assertion or announcement made by Buckman are «defines --- as». A reader of Haas and Simpson's paper cannot be sure that Buckman in his paper used the expression «defines --- as».¹ In other words, Haas and Simpson attempt to describe in their own terms an assertion or announcement intended by Buckman. What Buckman may have intended by the expression «defines --- as», if he used the term «define» at all, is a question without relevance to what Haas and Simpson intend to express by «define».

Speaking about «the geometrical meaning «of homology», corresponding members of similar figures being «homologous»», Haas and Simpson say, «It may, ---, be doubted whether Owen, when defining --- «homologue» as «The same organ in different animals under every variety of form and function», had this geometrical meaning in mind» (ibid., p. 320).

Several interpretations of this quotation from Haas and Simpson's paper are of interest. Here it will be interpreted in only one direction. They may have intended to tell readers that a certain hypothesis may be doubted as to its validity, namely the hypothesis that Owen by the definiens expression «the same organ in different animals under every variety of form and function» (as occurring on page 379 of one of his works) intended to express a connotation similar to the above-mentioned geometrical meaning. Implied in this critical remark by Haas and Simpson is the hypothesis that Owen intended to define «homologue» in the sense in which Haas and Simpson use the term «define». Thus, a description of something is im-

V. ELEMENTARY ANALYSIS

plied, which possibly is conceived to be a synonymy hypothesis or announcement made by Owen.

Elementary analysis may show—or make plausible—that certain synonymy sentences express under certain conditions a kind of hypothesis having definite characteristics a, b, c. The analyst may be tempted to ask, What sentences other than synonymy sentences (in the accepted sense) express at least occasionally a kind of hypothesis with characteristics a, b, c? Roughly, having found out about certain cognitive meanings represented by a (rather arbitrarily delimited) sample of sentences, one is interested in finding other sentences expressing the same or very similar cognitive meanings. We shall include under elementary analysis an investigation concerning which sentences other than synonymy sentences sometimes or mostly express hypotheses of the kinds that synonymy sentences sometimes or mostly express.

A further main task of elementary analysis consists in attempts to describe hypotheses assumed expressed by heteronymy, ambiguity, and interpretative sentences.

Descriptions of interpretative hypotheses meet the same difficulties as those of synonymy and ambiguity hypotheses, and the difficulties are often aggravated by even less adequate marginal references than for the synonymy hypotheses. The definiens expression is often used quite naively, without consideration of how it will be interpreted by the public.

Of special importance are descriptions of attempts to make lists of interpretations and of debates between advocates of different lists.

The foregoing tasks are all concerned with *descriptions of metaoccurrences* of expressions and sentences. The aim is to describe (and classify) what seems to be expressed by declarative sentences containing metaoccurrences.

Synonymy announcements as well as normative synonymic and interpretative definitions are also subjected to attempts at accurate description, mostly involving precization. To make and establish such descriptions is a further task of elementary analysis as here conceived. Whereas the assertive function of sentences seems to be fairly homogeneous and not too difficult to describe, the many variations of normative statements (imperatives, proposals, decisions, and so on) add to the complexity of the analyst's task.

The foregoing examples of descriptions that possibly are intended to be descriptions of synonymy hypotheses or announcements might be re-

peated here as examples of descriptions that possibly are intended to be descriptions of normative or descriptive interpretative definitions. When, for instance, an analyst P says something like «Q defines a as b», it is not easy to figure out what P is describing, owing to the ambiguity of the term «defines» and the expression «a as b».

V.2. Interpretation of Definitoid Sentences in General

Let us use the term «definitoid sentence» for any sentence or system of sentences that is preliminarily assumed to express a normative, descriptive, or real definition. The analyst is confronted with the task of attempting a classification based on hypotheses about which are the most plausible interpretations of the sentences. Of the enormous number of definitoid sentences found in technical literature, scarcely one-fourth are such that one may, without further scrutiny, establish whether they express something closely similar to normative, descriptive, or real definitions, or combinations, or do not express anything closely similar to these structures. The reader is invited to inspect published lists of «definitions», for example, those of Ries (1931b: 208ff.) and Seidel (1935: 114ff.) concerning 'sentence'. Very few members of these collections are easy to classify. The analysis of definitoid sentences has therefore a broad field of difficult application.

A large number of the eighty-three «*definitionen*» quoted by Seidel have the form «a is b», a form that has for centuries caused confusion. As an example we may cite «Die Sätze sind die kleinsten in der betreffenden Redeumgebung grammatisch befriedigten (sinnvollen) Einheiten, in die eine sprachlich korrekte Rede zerlegt werden kann» (Ahlman 1883). A number of the «definitions» are not intended to be normative, descriptive, or real definitions—for example, «Wenn wir auf das Verhältnis zweier Begriffe Acht haben, so entstehen Sätze» (Crusius). A quotation from Husserl belongs to those very few that can be classified with a fair degree of certainty: «[d]och scheint es passender --- die Einheit von Sinn und thetischem Charakter als Satz zu bezeichnen». This is probably meant as something like a normative interpretative definition.

Despite the importance of distinguishing between normative and descriptive statements, and the frequent advice in that direction in philo-

V. ELEMENTARY ANALYSIS

sophical and scientific literature, such distinctions are often neglected and with serious consequences. It is seldom that the distinction is drawn as explicitly as in the following statement by Bertrand Russell (1931): «I shall adopt the arbitrary convention that «convince» is to mean «to satisfy by rational argument», for example, by adducing evidence in support of the proposed conclusion. I shall confine the use of the word «persuasion» to mean «to bring about the acceptance of a conclusion by methods other than that of offering grounds for rational conviction». Most people would, I think, say that «persuasion» covers what I have called «conviction». I have admitted that this is a correct usage, but it is inconvenient for my purpose.» Russell here clearly intends to give something closely similar to what we call a normative definition;² he does not intend to give a descriptive definition.

The distinction, which to us seems nearly as important, between a descriptive definition (a hypothesis of synonymy between expressions) and a real definition (a condensed characterization of things denoted) is more often neglected, even among analytical philosophers. One of the reasons that the distinction is so important is that a real definition can be tested as regards its tenability only if the definiendum has a well-established nonformulated usage, or if the sender of the real definition offers a normative definition by means of which he explains how he intends to use the definiendum. Very often, a proponent of a real definition unjustifiably presumes that others use the definiendum expression as he does. However, the real definition cannot perform both the task of giving a meaning to an expression, a connotation, and the task of giving a nonanalytical theory about the denotata delimited by the connotation of the expression.

In the following, we shall pay attention to a series of difficulties confronting those who try painstakingly to describe the hypotheses or announcements that we call normative, descriptive, and real definitions. In some cases it is sufficient to use rough descriptions and descriptions that are far from complete descriptions or reformulations, but we are interested in cases in which rough indications are not considered adequate. In cases of extensive debates about definitoid sentences or phrases (for example, «of the people, by the people, for the people»), the inadequacy of the usual levels of exactness (or rather, inexactness) is shown by frequent pseudoagreements and disagreements and other symptoms of confusion.

Examples of incomplete characterizations of normative, descriptive, or real definitions:

«Carnap defines 'value judgment' in such a way that value judgments by definition are excluded from all kinds of empirical test; ---» (Ofstad 1951: 44).

By this sentence, Ofstad says something about the (normative) definition that Carnap attaches to the term «value judgment». No complete description is aimed at. How Carnap formulates his definition is not revealed; this is not a description or quotation of a definitional sentence produced by Carnap, but a hypothesis about an expressed announcement.

A further example of incomplete description is found in the second part of the following quotation: «If «analogy» is to retain --- any technical meaning in comparative anatomy and phylogeny, it can be but the one implying function or use. This is the meaning given to this term by Owen (1843) and maintained in the biological sciences, though with certain qualifications, ever since.» (Haas and Simpson 1946: 324). Haas and Simpson seem to refer to a normative definition proposed by Owen. About that normative definition they assert that it implies function or use. It is not asserted that Owen proposes to use «analogy» for «function or use». The information intended is partial, not equivalent with a complete description.

V.3. Some Distinctions Exemplified and Tabulated

Suppose we aim at a description of normative and descriptive definitions, and choose definitions of «denote» and «denotation» in classical logic as our subject matter. As a preliminary step we shall have to state rather precisely what we mean by «classical logic», a term used somewhat loosely in contemporary philosophy. When this is done, we have specified a class of contexts to be investigated. Our conclusions will be hypotheses with direct bearing on this and only this class of contexts. We shall be responsible for descriptive characteristics of *every* formulation expressing a normative or descriptive definition within this field of intended application, but for none outside it.

Suppose the term «classical logic» is defined in such a way that the following formulation from *Formal Logic* (Bennett and Baylis 1939: 232) is included: «[a] term that signifies a class property is said to denote each of the members of the class determined by that property».

V. ELEMENTARY ANALYSIS

Our business as analysts would then be to find out whether the formulation, or a part of it, expresses an N- or Ds-, or N- and Ds-formulation relating to «denote», and, if necessary, to reformulate the supposed definition so as to make it more precise (receiver-precise) for the readers of the analyst's description, that is, the readers of this section.³

The analyst has to determine whether the cited formulation is an N- or Ds-formulation or both. It seems probable to us that Bennett and Baylis intend to *describe* the use of the word «denote» in certain contexts—for example, that they intend to give a Ds-formulation, a description of existing usage, by means of an expression that they hope readers will interpret as they do, or very similarly. On the other hand, they themselves use the word «denote» on their own, and we, therefore, and for other reasons, guess that they also intend to give a normative formulation. The analyst with scientific pretensions must carefully take into consideration what can be said for and against hypotheses about what the authors in this case intend. As an argument for the hypothesis that a normative definition is involved, I think it could be mentioned that Bennett and Baylis probably are aware of other uses of the word «denote», besides the one they mention, even within logic.

If we conclude that the cited formulation of Bennett and Baylis is an instance of a Ds- or N- and Ds-formulation within our field of investigation, other things have to be determined, for example, the limits of the context that Bennett and Baylis intend to cover by their definition (its intended field of application). Without a hypothesis on the limits of this context, we cannot make statements of the kind «In this instance Bennett and Baylis do not follow or use their definition» or «In this case Bennett and Baylis do follow or use their definition». It may be that they intend to use «denote» in the sense defined in all possible contexts, but it may also be that they do not pretend to use the word in that manner outside their texts on logic or outside discussions with persons presumed to have read the texts. They may not feel responsible for their usage in family quarrels or newspaper articles, or in texts of literary criticism.

From the quotation itself, very little may be inferred. «A term that signifies a class property *is said* to denote ---». The expression «is said» is fairly representative of the kind of words used to express synonymity hypotheses and also normative definitions. We shall leave the issue. It is our aim in this

chapter to show the kind of assumptions made even in the most elementary kind of analysis, not to perform an analysis.

The analyst will have to pay attention to the restrictive phrase «that signifies a class property». Do Bennett and Baylis intend to say that «denote» connotes something different according to whether a denoting term signifies a class property or signifies something else? Do they intend to give a general Ds- or N- and Ds-formulation relating to «x (a term) denotes ---», or only a special, restricted formulation referring to «x (a term signifying a class property) denotes ---»? We shall have to decide for or against these kinds of hypotheses about the field of intended application. If we do not, we cannot easily judge whether Bennett and Baylis express a tenable or an untenable hypothesis. There is probably in the authors' texts material relevant to the hypothesis that they intend a rather general definition. If such material is found and used, the analyst's description of Bennett and Baylis's hypothesis probably ought to consist of expressions that will be interpreted as the analyst interprets the hypothesis, even though the receivers are not familiar with all of Bennett and Baylis's texts. Their formulation is then too tied up with their texts in general to allow any isolation from those texts.

A description of a definition as here understood is not simply a collection of quotations, but an exposition of definitions formulated in such a way that readers of the exposition interpret the formulations as closely as possible to the interpretation of the sender of the definitions. The analyst is a kind of mediator, taking care of the necessary reformulations.

In the particular instance mentioned above, the reader of the description of definitions cannot be supposed to know exactly how Bennett and Baylis intend to delimit the class of terms said to signify a class property. He may not, for example, be able to interpret the expression «each of the members of the class» in the manner that Bennett and Baylis do. They themselves discuss that point, and the material thus available may profitably be used to reformulate their formulation to make it more receiver-precise to the readers of the description.

So far, I have tried to direct attention to the distinctions among the following:

1. The context F investigated directly by an analyst. This is *included* in the defined field of application of the analyst's description. In the ex-

V. ELEMENTARY ANALYSIS

ample considered, we limited ourselves to an examination of a single passage in a book by Bennett and Baylis, and only superficially took into account the rest of that work. The passage corresponds to what is called «Formulation group No. X within the field» in figure 1.

2. The field E intended to be covered by an ordered description of definitions based on the investigation. This corresponds to what is called «The field E to be covered by the description» in Figure 1.

The analyst's description has the character of a hypothesis, and its intended field of application E may be much greater than the directly investigated context F. In the example under consideration, the field E is the whole of classical logic.

3. The context intended to be covered by an author of an N-, Ds-, or N- and Ds-definition. This is the field within which the sender of an N-definition intends to use the definiendum as a synonym of the definiens, or the field within which the author of a Ds-formulation claims that the definiendum is used synonymously with the definiens. If it is a question of a definition with double aspects, it may be necessary to distinguish between two fields of application, that of the expressed normative definition and that of the descriptive definition.

Further, we wish to stress some implications of the rather trivial difference between a definition and a formulation of a definition. If an analyst finds a formulation that he thinks can be interpreted so as to express a definition, his interpretation may be based on extensive study of the particular terminology found in the context of the formulation. If, now, the analyst limits himself to quoting the formulation in his description, it may be practically impossible for the readers of that description to arrive at the same interpretation. It will be necessary for the analyst to rewrite the definition in search of a formulation that will induce his readers to interpret it in the best possible harmony with the intention of the author. We therefore stress the possible difference between an original formulation—an object studied by the analyst—and the formulation of the analyst in his description of definitions.

If, for example, we compare various axiomatizations of a field, there may be formulations of definitions that are identical in all systems, in spite

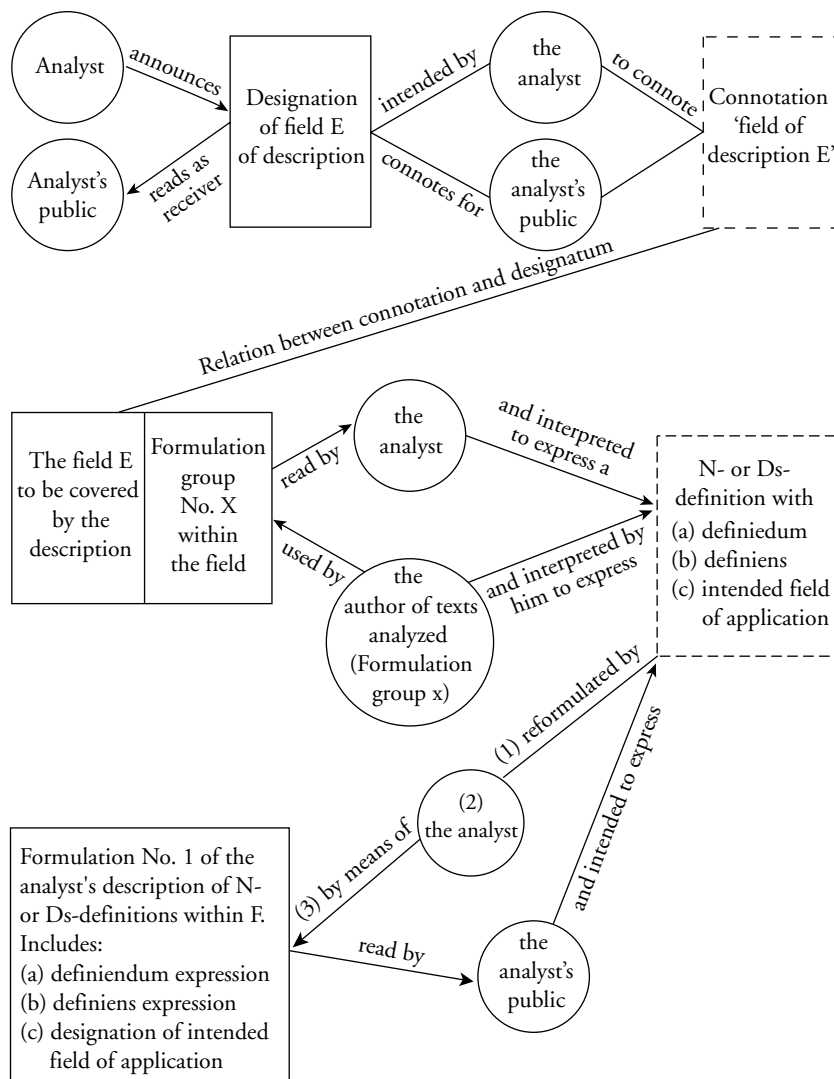

Figure 1. Some items involved in the construction and use of a description of normative or descriptive definitions. Persons involved are indicated by circles; expressions, by rectangles; and significations (connotations), by rectangles with dashed lines.

V. ELEMENTARY ANALYSIS

of vast differences in their meanings. These are given by rules or by «implicit definitions». For example, there may be said to be many propositions in Russell and Whitehead's *Principia Mathematica* that are «propositions» in other systems (e.g., in Lewis's system of strict implication). An analyst describing the «propositions» should not, however, use such an ambiguous formulation, but should limit himself to asserting that some *expressions* of «propositions» are the same. His description of the propositions involved may show them to be very different.

If the original formulation cannot be interpreted so as to indicate its intended range of application, the analyst has to make hypotheses as to this range. Such hypotheses we take as parts of the description of definitions.

In the description we expect, therefore, to arrive at formulations expressing all three components of the definition: the definiens, definiendum, and intended range of application (see figure 1).

Let us suppose that we decide to describe and test hypotheses of an analyst who publishes a description of certain N- or Ds-definitions. We may in that capacity call ourselves «meta-analysts». As part of the material available for our investigation, we have the analyst himself, if he is alive and agrees to be observed. We have, further, his designation of field of description E, and the formulation group x within the field F of investigation. If we are lucky, we shall also have at our disposal the author of the texts analyzed. Finally, we are, as meta-analysts, able to point out a formulation No. 1 of the analyst's description of normative or descriptive definitions within F.

Other items illustrated in figure 1 are usually less readily observed. What is the analyst's public? It can hardly be certain definite people at definite moments. We may as meta-analysts find out that certain people without doubt should be classed as denotata of the 'public', and that these people seem to have interpreted the designation of field E as has the analyst, but normally we cannot say more than that we have provided some instances of confirmation of a hypothesis of the analyst.

The so-called «field E of description» can be delimited only by testing interpersonal synonymy hypotheses. As meta-analysts, we shall have to investigate the interpersonal synonymy of the field designation for the analyst and his public. If we strongly confirm the interpersonal synonymy, the hypothesis illustrated by making the analyst and his public share one

and the same connotation is strongly confirmed. If it is not confirmed, we shall have put two connotations into the picture, as shown in figure 2.

The field E to be covered by the description may in some cases be a small collection of formulations readily surveyed, or the field may be «given» only as the designatum of a designation such as «classical logical texts». In the latter case, the field has no definite boundaries. Different investigators will almost certainly delimit the field in different ways, and, probably, no investigator will try to survey the whole field (as interpreted by him). Thus, the neatly drawn rectangle representing field E (figure 1) must not be taken as a symbol of one definite, easily surveyable observational field, such as, for example, a small collection of formulations arranged in an easily surveyable list.

As for the dotted rectangle that symbolizes what formulation group x expresses, we can say about it what has already been said in reference to the connotation 'field E of description'.

We stress that most of the items illustrated are more or less unsurveyable and unobservable (in many plausible senses of that word). They are intervening variables, in the terminology of E. C. Tolman and C. L. Hull.

If the description is not perfect in all respects—an expression I use with low definiteness of intention—some of the areas illustrated in figure 2 will have to be duplicated. The whole illustration will then be seen as if out of focus.

In figure 1 there are two designations of the intended field of description E. This is to remind us of the difficulties that arise from the habit of repeating at various intervals what field should be investigated and thereby using different designations. If the analyst selects one field as the main one and the «standard» from which interpretations should proceed, then there is no complication. Figure 2 is adapted to the case of two designations on equal footing. As an analogy, consider a standard meterstick in Paris and in New York, both defining the length of one meter.

The designations of field intended to be covered (for example, «classical logic», «works of Bryce on democracy», «William James on truth», «common usage») give rise, according to the illustration, to three different interpretations, one by the analyst and two by the public. The latter may be classed as misinterpretations. The fields E corresponding to the different interpretations are different, and the formulation x picked out as «defini-

toid» occurs within the field as conceived by the analyst, but not within those conceived by the public.

The boundaries of the connotation are shown as incomplete to remind us of the indefiniteness of intention always present. The effect of the indefiniteness is symbolized by the incomplete boundary of the field E.

It is usually difficult or impossible to single out one definite formulation as the one expressing the definition. There may be several sentences and often not in a series, but with irrelevant ones in between. In the illustration two parts of the formulation group correspond to how the analyst has delimited the so-called «formulation group x». According to the interpretation of the author of the text analyzed, there is a third part of group x, which it is necessary to take into account. It belongs to the formulation of a definition, and without it, parts one and two do not express any of his definitions. The definition expressed by the formulation group x is conceived somewhat differently by the author and the analyst. The most plausible interpretation, according to the analyst, gives descriptive definition No. 1; a less plausible interpretation, in his opinion, gives descriptive definition No. 3. The author of the text entertains the opinion that his intention most probably was that of expressing descriptive definition No. 3. He thinks it less probable that descriptive definition No. 2 covers his intention, and does not think No. 1 gives a plausible interpretation at all.

As meta-analysts, we find that the analyst has in his description given two reformulations of the definition he believed the author tried to express. The reformulations are synonymous for the analyst, both expressing descriptive definition No. 1. To the public, the analyst's versions express two other definitions: No. 2, which is a plausible, but not the most plausible, interpretation of the author according to his own hypothesis, and No. 4, which is considered plausible neither by the analyst nor by the author.

In elementary analysis there are a host of complications not hinted at in figure 2. Thus, we have in our illustration assumed that we can directly compare connotations (and assertions), whereas we shall, in practice, have to compare precizations, using complicated procedures. Even if the analyst, his public, the author, and the meta-analyst all are available and willing to discuss what they mean by their talk, we shall meet great and methodologically important difficulties when trying to confirm or weaken the hypo-

V. ELEMENTARY ANALYSIS

thetical descriptions of the analyst. Elementary analysis is «elementary» in the sense of «propaedeutic», not in the sense of «easy».

The intention of the author of a definition may fall short in many ways that may profitably be distinguished. Let us suppose he intends to give a formulation of a definition—a *convenient* and *fruitful* normative definition or a tenable (correct) descriptive definition. It is not the business of a describer of definitions to judge whether the underlying intention has been successfully realized. Whether the formulation is fruitful or not fruitful, the author in both cases intends to give a formulation of a *definition*, and to describe the intended definition is in both cases the job of elementary analysis. Sometimes, however, even the intention itself may not be complete. The author's formulation may, for example, lack any indication—explicit or implicit—of range of application, because of lack of definiteness of intention. The description of definitions has to take into account such shortcomings and indicate what the minimum criteria are for stating that something is presented as a realization of an intention to give a definition. As analysts of definitoid formulations, we are concerned with the basic characteristics of any normative, descriptive, or real definition, fruitful or not fruitful, tenable or not tenable.

V.4. Illustrations of Elementary Analysis

Illustration 1

A field of description of practical importance is found in the definitoid statements that appear in traffic regulations. A vast number of cases before the courts are decided on the basis of normative definitions of «blind curve», «emergency vehicle», and other such terms. Let us suppose that we are interested in material relevant to a description of that field, and that we find as part of the text material to be investigated the pamphlet *Traffic Regulations*, by police commissioner L. I. Valentine. Section 1 opens with a series of «definitions»:

The following terms when used in these regulations unless otherwise expressly stated, or unless the context or subject matter otherwise requires, shall be deemed to mean and include:

1. «Authorized emergency vehicle» shall mean vehicles of the fire department (fire patrol), police vehicles, ambulances, and emergency vehicles

of federal, state, or municipal departments or public service corporations and such other vehicles as are designated or authorized by the Police Commissioner.

2. «Bicycle» shall include any vehicle consisting of an arrangement of a combination of two wheels, one following the other, supported by a frame, propelled by the feet acting on pedals.
3. «Blind curve» means a curve on a two-way street where the straight-away of the street is not visible from the center line of the street at the start of the curve.

We use these formulations as a first instance of easily describable normative definitions because they are unusually explicit. So far I can see, without having made any empirical investigations, they offer unusually strong precisations of some rather ambiguous and vague expressions. At the same time, they do not invoke technical vocabulary beyond the scope of the majority of the intended public. However, even such recommendable specimens of N-definitions offer some problems for the elementary analyst.

The quoted passage can be divided into an introductory note and three numbered formulations. The introductory note says something about the three terms referred to in the numbered formulations. It says that each of them «shall be deemed to mean and include:». In the numbered formulations, however, somewhat different expressions are used: «shall mean», «shall include», and «means». A reformulation seems warranted. It is to be noted, however, that it is based on highly uncertain assumptions.

When used in these regulations unless otherwise expressly stated, or unless the context or subject matter otherwise requires:

1. «Authorized emergency vehicle» shall mean vehicles (etc.).
2. «Bicycle» shall mean any vehicle (etc.).
3. «Blind curve» shall mean a curve (etc.).

In this reformulation adapted to quite another public, namely, the readers of this section, the talk about what is included is left out on the assumption that its only function was to remind us that if «a» means b, all things denoted by «b», for example, all things included, are denoted by «a».

A sentence of the kind ««Bicycle» means and includes any vehicle of kind A», is of some interest, because «means» requires that «any vehicle of kind A» express a connotation (concept), whereas «includes» requires that «any vehicle of kind A» designate certain things. Reformulating in more

V. ELEMENTARY ANALYSIS

pedantic terminology, we might say, ««Bicycle» means ‘vehicle of kind A’, and the class of bicycles includes the class of vehicles of kind A». When the sentence is thus formulated, the second member of the conjunction follows from the first, but not vice versa.

From the nature and character of the *Traffic Regulations* booklet, it seems justified to assert that the following expressions (among others) are intended as complete synonyms within that booklet: «shall be deemed to mean and include», «shall mean», «shall include», «means», «shall mean and include», «means and includes».

All these expressions occur within the text covering the first fourteen definitions. The ninth definition has no expression of that kind:

«9. «Designated parking space». That part of any street designated by competent authority ---.»

On the basis of previous sentences, it is justifiable to assume that the pair of sentences in item 9 are intended to be synonymous with «The expression «designated parking place» shall mean that part of any street designated by competent authority ---».

Taken in isolation, an expression such as «includes» might be expected to refer to a part of the denotation of something, not the connotation. The introductory statement («The following terms ---»), which covers all subsequent definitions, and a similarity among the various formulations designated by 1, 2, 3, etc., suggests that connotation rather than denotation is referred to. This conclusion is not weakened by inspection of the definiens formulation of item 2. The definiens is such that it may well represent a connotation rather than a denotation. We stress, however, that decisions on questions of interpretation are shaky and largely intuitive.

The three sentences are reformulated as normative interpretative sentences («a» shall mean b) rather than as normative synonymy sentences («a» shall mean the same as «b»).

In the present case, it is rather certain that the interpretative sentences express something that involves the corresponding synonymy sentences, and *possibly* assert something more. The additional content might be formed as an answer to the question ««a» shall mean the same as «b», but what does «b» mean?» In this work we do not try to formulate what answer is implied in the interpretative sentence other than the rather trivial one:

«b». That is, we treat the interpretative sentence (1) as if it were synonymous with the synonymity sentence (2):

- (1) «a» shall mean b.
- (2) «a» shall mean the same as «b», and «b» means b.

If the analyst, in his description of Valentine's N-definitions, uses Valentine's own definiens expressions, he limits himself to a quotation of them. More interesting is the case in which the analyst tries to convey to his public the intended meaning of the definiens expressions by using other words. The analyst may, for example, say, «By «vehicles of the fire department (fire patrol)» Valentine means the same as «any vehicle of the fire department that is a fire patrol vehicle». He evidently does not intend to include all vehicles belonging to the fire department». If the analyst uses his own words, it is convenient for him to give his description as a «that» formulation: «Valentine announces *that* «---» shall mean . . .».

Illustration 2

Here, our field of description is definitoid statements about «patent claim» in technical literature. Our field of investigation is a statement from Alf B. Bryn's *Patentloven* (Patent Law 1938).

On page 38 Bryn mentions some «words which are permanently used in connection with patent cases, and which in this connection have their special connotation ---». One of these designations is «patent claim».

Patent claim[:] A definition that comes at the end of the patent description and indicates what the applicant holds to be his invention and wishes to have patented.

Let us suppose that the analyst aims at a description of Ds-formulations of «patent claim». In this case he may write:

Context in which the instance is found:	A. B. Bryn, Patent Law, page 39
Definiendum expression:	patent claim
Definiens expression:	(as quoted above)
Range of application:	patent cases

It is to be expected that the expression «patent cases» will create some difficulties in practice. As a designation of the intended field of validity, it

V. ELEMENTARY ANALYSIS

will probably give rise to conflicting interpretations among those who are not trained jurists. If the description of Ds-formulations is written for a public with poor knowledge of law, it would presumably be desirable to give a simple definition of «patent cases», as understood by Bryn, or to substitute for «patent cases» the definiens expression in such a popularizing definition. We mention this to give an example of how the analyst's description may differ from the original.

It is presumably Bryn's aim to help students of law get a better hold on the use of the expression «patent claim» than they would by just reading instances of use. He may be said to aim at a delimitation, and therefore a precization, of a term that is used too loosely in ordinary life to serve a student of law. He probably does not aim at a precization among professional patent lawyers. For that aim, the definiens is probably too elementary.

V.5. Levels of Preciseness of Descriptions of Definitoid Statements

In an article called «The developing science of democracy», reprinted in *The Analysis of Political Behavior* (1951), H. D. Lasswell offers a definitoid group of formulations that has the important function of delimiting the definitional subject matter of a prospective science—the science of democracy. The formulations are found on page 8 and run as follows:

A democratic government can be defined in terms of shared power, a democratic society in terms of shared deference (power, respect, insight) or shared influence (deference, safety, income). What are the limits within which sharing may vary in a government or in a society that is entitled to be called «democratic»? With respect to power, we may stipulate that a democratic government authorizes majority participation in the making of important decisions. The majority may express itself directly (direct legislation) or indirectly (elected officials). The majority must participate actively (a large majority—let us specify a two-thirds majority—must qualify to vote and take part in elections). The overwhelming majority must be free of intimidation. Moreover, they must have confidence in their capacity to exert effective control over decisions, whether or not they vote on any given occasion. Communities are democratic in the degree to which they conform to them.

The formulation cluster contains two definiendum expressions, «democratic government» and «democratic society». A third expression,

«democratic community», probably intended to be synonymous with the second, can be constructed on the basis of the last sentence quoted. The definiens expressions are relatively complicated and need rearrangement if we, as analysts, wish to compare them with those of other authors. It is of much greater importance, however, to know exactly what kind of statement Lasswell wishes to make.

Does he intend to give a normative definition? The book is not a textbook, and Lasswell is not the kind of person likely to try to coerce his readers in matters of terminology. We may, therefore, safely assume that he does not intend to express an imperative. More plausibly, he tries to express decisions: decisions to use «democratic government» and «democratic society» as indicated by the definiens expressions within his own works. Given that the whole article is rather programmatic and favors the development of a science of vast complexity, the definition is probably also to be interpreted as the announcement of a proposal directed to competent readers.

Does Lasswell intend to give a descriptive definition? There are strong reasons to believe that the definitoid sentences are not intended to be entirely normative. The word «democracy» is used numerous times in the article before the quoted passage. There is no indication that Lasswell intends to introduce a usage that differs from what he expected readers to understand by the word «democracy» before page 8. On the other hand, there are indications that some parts of the quotation are meant to be less descriptive than others. He says «let us specify a two-thirds majority», but he does not say «let us by «democracy» mean ---».

Someone might say, «Let us see what Lasswell says, and not speculate about what he might possibly mean. Lasswell says, «A democracy can be defined ---». Therefore, what Lasswell intends is to give *one possible* definition, not *the* definition of democracy. Obviously, he refers to the word «democracy» as used so far, and he tries to express one of its senses, that is, to offer a precization, a descriptive definition».

To this we may say that the indicative form of «can be defined» in no way implies that the expression cannot function in a normative definition. On the contrary, most N-definitions have an indicative form, so far as I can judge. Moreover, the word «can» does not imply that the author limits his claim and indicates the existence of other adequate definitions (and not only definitional formulations). He also uses the expression «Communities *are* democratic if ---». In this expression there is no «can». If the last sentence

V. ELEMENTARY ANALYSIS

functions to recapitulate and sum up the previous ones, it is difficult to see how the dogmatic «are» can be reconciled with the weak «can be defined» if we stick to «strict word meanings», as the hypothetical analyst seems to do.

Without going into further details of argumentation, I shall venture to assert the hypothesis that Lasswell intends to state something very similar to what is called a precization in chapter I, but that the inclusion «let us specify a two-thirds majority» does not belong to the definiens of the descriptive definition. (It belongs to the normative definition intended, I suppose.) The intended field of application of the description of usage is not hinted at. Possibly, Lasswell refers to twentieth-century use of «democracy» in England and the United States among students (professionals and amateurs) of political theory and of law. This is only a guess. It is fairly certain, however, that Lasswell does not intend to cover every use of the word «democracy». Thus, he probably does not think that the use made of the word in *Pravda* harmonizes with his definition.

Does Lasswell intend to give a real definition, a definition as a condensed characterization of democracies? That is, does he give a condensed characterization of denotata of a concept not introduced by the quoted passage? There is no part of the definitoid group of formulations that points toward real definition rather than descriptive definitions if the methodological trend of the author suggests influence from traditions foreign to the doctrine of real definitions. The methodological trend of Lasswell may roughly be called «Anglo-American empiricism», and the use of the word «define», therefore, tends to point to normative or descriptive definition rather than real definition. The trend is enhanced in cases of influence from test-psychology and parts of social psychology in which terms are more or less operationally defined by criteria that are admittedly to some degree arbitrary. These parts of social psychology are well known to Lasswell.

Let us try to reformulate the quoted passage and work out some precizations of it. The following formulations and announcements express to me, and I hope to my readers, some plausible precizations of Lasswell's passage or parts of it:

- A. «A democratic government» I propose should be used synonymously with «a government that authorizes majority participation in the making of important decisions, and in such a way that

1. The majority participates actively. A majority of at least two-thirds qualifies to vote and takes part in elections.
2. The overwhelming majority is free of intimidation.
3. The overwhelming majority has confidence in its capacity to exert effective control over decisions, whether or not it votes on any given occasion».

B. «A democratic government» I propose should be used synonymously with «a government that authorizes majority participation in the making of important decisions».

C. «A democratic government» is, by students of forms of government, used synonymously with «a government --- [the rest as A or as B]».

D. «A democratic government» is used, and shall in the following be used, synonymously with «a government --- [the rest as A or as B]».

E. «A democratic society» I propose should be used synonymously with «a society in which

1. The majority participates actively in the making of important governmental decisions.
2. The overwhelming majority is free of intimidation.
3. The overwhelming majority has confidence in its capacity to exert effective control over decisions, whether or not it votes on any given occasion».

The list of plausible interpretations that are relevant to at least one purpose of description could be extended indefinitely.

A system of descriptions of a definition can be worked out on the following lines and with contents classed as follows:

- I.a. Descriptions 1) on the level of preciseness of the author (Lasswell) and 2) with highly competent people as the intended public (professional students of forms of government and related subjects) of the elementary analysis.
- I.b. Descriptions 1) on the author's level of preciseness but 2) with people who are not highly competent as intended receivers.
- II.a. Descriptions 1) possibly transintentional, on higher levels of preciseness than that of the author and 2) with highly competent people as the intended receivers.

To get higher levels of preciseness, it will be necessary to reformulate with a view to excluding some possibilities of interpretation that are present when highly competent people read the passage within its context. What should be taken as «the context» must be decided on. We suggest

V. ELEMENTARY ANALYSIS

that chapter 1 of *The Analysis of Political Behavior* be taken as standard context and not the whole book, because chapter 1 was originally an independent essay published in 1942 in *The Future of Government in the United States: Essays in Honour of Charles E. Merriam*.

Even in cases of descriptions of type I, reformulation may prove necessary because the description cannot include the whole chapter, and the reader of the analyst's description is therefore handicapped in relation to the reader of the chapter. To make the passage as precise among the intended receivers of the analysis as it is when read by the same persons as part of the whole chapter, we shall probably have to reformulate, because of interpretational vibrations caused by elimination of context (chapter 2, section 13).

II.b. Descriptions 1) possibly transintentional, on higher levels of preciseness than that of the author and 2) with people who are not highly competent as the intended public.

On the whole, we must expect descriptions of type II to be rather lengthy, especially in the case of a public with very little knowledge of theory of government. In limiting cases we shall get descriptions that are so lengthy and contain so much information that they must be conceived of as courses of study that make the receivers more competent, and therefore lead them out of their original class of competency.

III.a. Descriptions 1) on lower levels of preciseness than that of the author and 2) with highly competent people as the intended public of the analysis.

III.b. Descriptions 1) on lower levels of preciseness and 2) with people who are not highly competent as intended receivers.

This class of descriptions (type III) contains popularizations. Maybe it is fruitful to precise «popularization» in such a way that precisations can at the same time be popularizations. Thus, the word might be introduced as follows: «a *popularization* of a definitoid statement» shall mean the same as «a description of the statement with a less competent group of people as the intended public».

The levels of preciseness mentioned in the above classification can be measured only in relation to a group of people. The group of people of most interest to the elementary analyst is his own intended public. This means

that the level of preciseness of the author (in the above example, Lasswell) is measured in relation to the intended receivers of the elementary analysis. In other words, it is asked, How would the public reading the analysis have understood Lasswell if, instead of reading the analysis, it had read the original? What is the ratio between the range of misunderstandings that would occur in reading the original and the range of misunderstandings that occurs in reading the description constructed by the analyst? If the latter range is narrower and part of the range of the former, the level of preciseness of the analyst will, according to the above convention, be said to be higher than that of the author.

A definitoid statement such as the quoted passage from Lasswell may be found to contain several definitions even if only one interpretation of each part of the passage is used. Thus, in the quoted passage, several expressions seem to function as definienda expressions:

1. «democratic government»,
2. «democratic society»,
3. «democratic community»,
4. «degree of democraticity of a government»,
5. «degree of democraticity of a society»,
6. «degree of democraticity of a community».

Expressions 4–6 do not directly reproduce expressions occurring in the quotation because this would be fairly difficult. Expressions 2 and 3 and expressions 5 and 6 are plausibly intended to express identical definienda. A great many possibilities are relevant to the difficult question of determining *exactly* which expressions in the passage are intended to function as definiens expressions for the definiendum expressions listed. The sentence «The majority may express itself directly (direct legislation) or indirectly (elected officials)» may be interpreted as a part of some definientia expressions, or as an elaboration or elucidation added to such expressions. The argumentation for or against these possibilities will necessarily be rather uncertain.

With regard to the question of which definienda expressions are connected with which definientia expressions, there are various interesting interpretations. Thus, a democratic society is said to be definable «in terms of shared deference (power, respect, insight) or ---». Now, with respect to

V. ELEMENTARY ANALYSIS

power, maybe Lasswell would insist that in a democratic society there must be a government that «authorizes majority participation in the making of important decisions». Or, maybe the just-quoted expression is meant only as part of a definiens related to «democratic *government*». It seems to me that there are arguments in favor of both interpretations.

Anyone who thinks that these distinctions are of no importance is invited to try to classify governments, societies, and communities by means of the quoted passage. We suggest that, for example, the attempt to classify the governments, societies, and communities of the southern United States from 1860 to 1948, of Norway from 1820 to 1890, and of the Spanish-American republics will show the necessity of strong precisations and therefore of many distinctions. On the other hand, it may be conceded that a serious attempt at classification on the basis of definitions is unduly optimistic in the social sciences, wherein perhaps the signal function of words is dominant and the symbolic function still rather undeveloped.

No attempt is made in this section to find out exactly what purpose the quoted definitoid statement of Lasswell is intended to serve. We have outlined *possibilities* of description on the basis of a plurality of purposes. Thus, there is in the section no direct criticism of the passage. In terms of the classification of pretended level of preciseness, our illustration does not make any definite claim to furnish more precise formulations than the author, but rather to develop material of use for descriptions of higher levels of preciseness. As our receivers, we have intended a highly competent group interested both in the theory of democracy and in semantics.

Suppose we decide to make a fairly precise description of that which we suppose Carnap (1936: 435ff.) intends to convey by his «definitions». The definitional formulation is begins with «We will say that the confirmation of S is completely reducible ---». Just what is intended by sentences of the form «We will say that ---»? In all, seven of Carnap's definitions make use of that phrase. Does the phrase express a decision (in plausible psychological or social-psychological senses)?

It cannot be our purpose here to deal at length with psychological descriptions of what decisions are, how one tests for whether a decision has taken place, and what authors intend when they express decisions. What we wish to point out is the imminent danger of overestimating the definiteness of intention with which such phrases are used. To reduce the dan-

ger it is appropriate to study, for example, other phrases that Carnap uses in the sentences called (or expressive of) «definitions». Of the thirty numbered definitions and subdefinitions in the first half of «Testability and meanings», sixteen make use of the phrase «--- is called ---», for example, «A predicate 'Q' is called reducible --- if ---». Seven contain the phrase «--- is said to have --- if ---», for example, «A sentential function is said to have molecular form if ---».

It is unlikely (but of course possible) that Carnap intends to convey different kinds of announcements by means of the different phrases. Therefore, the analyst will probably be led astray if he looks for fine shades of meaning possibly associated with the expression «will say» that are not associated with «is said to have» or «is called». To describe as exactly as possible what Carnap intends to express, we must indicate something that is adapted to both the «is called» announcements (or assertions) and the «will say» announcements (or assertions). The wording and context of his definitions do not give us much material from which to draw inferences about his definitions. We are in such cases justified in relying tentatively on his sentences about «definitions» in general—his doctrine about definitions. This must be done with strong reservations, because an author cannot be expected to follow his doctrine with complete consistency. A doctrine about definitions may, however, be taken as symptomatic of dispositions of particular usages of sentences such as «--- will be called ---».

Suppose the analyst tells his audience, «The sentences headed «Definitions» in the paper «Testability and meaning» are, by its author, intended to *express* a series of *decisions* on his part about how to use certain expressions within the text at issue». Two questions immediately arise: To what degree are the ambiguous terms «express» and «decision» expressive (for the analyst) of the meaning intended by Carnap? What are the most probable ways in which the analyst's public will interpret the terms «express» and «decision»?

To find material relevant to the first question, one may use Carnap's own «definition»(?) of a subclass of definitions: «[b]y an (explicit) definition of a descriptive predicate 'Q' with one argument we understand a sentence of the form $Q(x) \equiv \dots x \dots$ where at the place of ' $\dots x \dots$ ' a sentential function—called the definiens—stands which contains 'x' as the only free variable» (Carnap 1936: 439). An examination of evidence in favor of

V. ELEMENTARY ANALYSIS

the assumption that $Q(x) \equiv . . . x . . .$ is intended to express decisions in vernacular or psychological connotations, would lead us into detailed examination of the function of such expressions within the texts of Carnap and others, and possibly to the use of questionnaires and interview methods aimed at stimulating Carnap to produce theories about his own usages.

Logicians use a variety of expressions to indicate normative definitions and related announcements and predictions. Thus, in the short introduction of the article «A basic logic» by F. B. Fitch (1942: 105), the following phrases are used: «by --- will be meant», «--- is used in this paper as a synonym for ---», «--- is to be understood as meaning the same thing as ---», «--- is said to be ---», «--- may also be called ---», «--- will be called ---», and «--- is ---». An example of the last form is «A calculus is a «combinatory calculus» if its «formation rules require only a single binary mode of combination of expressions»».

The aim of elementary analysis of definitoid sentences is not merely to give quotations, but somehow to convey to the readers of the analyst's text the contents of decisions or assertions assumed to be intended by definitoid sentences. The variation in terminology is one of the complicating factors.

V.6. Descriptions of Explicit Definitions

If an author gives one explicit formulation expressly called «a synonymity hypothesis» and expressed in language well adapted to the analyst's public, the analyst's job as a describer tends to be reduced to that of merely quoting the author's formulation and adding an introductory note, «This is the hypothesis: ---». In other cases, there are still definite formulations on the part of the author that more or less certainly are meant to express a hypothesis very similar to a synonymity hypothesis, but are less precise, less complete, and perhaps mixed together with other hypotheses. Still more complicated cases are those in which the author has produced scattered formulations that together seem to reveal a hypothesis, or that can be explained by the assumption that he makes a hypothesis but presumes it to be known to the reader and therefore does not give a complete expression of it.

In still other cases, the analyst's work will more closely resemble that of a constructor of rather indirect and speculative theories than that of a de-

scriber: he may find it fruitful to ascertain which hypotheses the author *might* have had in mind, such that his scattered sayings are rendered coherent and expressive of a synonymy hypothesis. This activity may involve transintentional precisations and may have the character of an attempt to improve and make fruitful obscure parts of an author's work. The result may be presented as possible explicata of the author's formulations, or as other kinds of so-called rational reconstructions of them.

A special case of considerable importance should be noted: that in which an author makes formulations that seem to be intended as expressions of conceptual characteristics, but makes no formulation intended as a complete conceptual determination. These characteristics may belong to a normative or descriptive, *unstated*, definition.

In this and in other cases in which there are no formulations that seem to be intended as *expressions* of a (complete) definition, one can say that there may be, nevertheless, an unexpressed definition intended by the author of the text surveyed. The term «intended», as used technically, refers to intended meaning of expressions. However, one may say that the author probably has a definition, possibly unexpressed, that to some extent regulates what he says expressly in his texts. This is no more speculative than to look for opinions that people entertain but do not express.

When H. Ofstad (1950b) says that he tries to find the descriptive definition of «general legal norm» intended by Hans Kelsen, what Ofstad seeks is the descriptive definition entertained (possibly as an unexpressed opinion) by Kelsen. Kelsen's assertions, if they are to be meaningful and tenable, seem to *presume* such a descriptive definition, and a normative definition with the same definiens formulation. If no such definitions are held and as a rule used by Kelsen, it is of interest to construct some that are adapted to Kelsen's assertions and to make them coherent and as tenable as possible.

V.7. Description of Definitions and Philosophical Analysis

The task of describing and interpreting definitoid formulations may be considered trivial and unphilosophical. Nevertheless, the task is clearly involved in philosophical analysis and, more generally, in various kinds of theoretical work in science, law, and administration. If anybody judges the

V. ELEMENTARY ANALYSIS

task to be too trivial or unimportant, he should be careful not to rely on assertions that presuppose such investigations. If he does rely on such assertions, either he will have to give up pretensions of having a critical habit of mind, and thus give up research, or he will perforce have to carry out investigations that he may not find interesting. If he does not rely on such assertions, he may use «if» or «suppose that»: «if by «a» is meant «b», *then* ---».

Among the theories presupposing more or less strict and more or less exhaustive descriptions of definitions, we especially call attention to the following kinds:

«In philosophy the term x is defined as follows: ---», «Bryce defines «democracy» as follows: ---», «The pragmatists say that «truth» means ---», «According to Tarski, the traditional notion of «truth» is ---», «A democratic government has always meant one in which ---»

«He does not follow his own definitions», «In the discussion, contradictory definitions are given ---»

It follows from the notions introduced, that ---»

The definitions in Kant's works ought to be made more precise or modified in some cases, because ---»

His system of definitions is unfruitful ---»

Very often, philosophers give an exposition of the opponent's views that is inadequate for the purpose of interchange of opinions. Of the hundreds of formulations pretending to state what pragmatists say they mean by «truth», very few can be called plain, honest reproductions or interpretations of statements representative of William James, F. C. S. Schiller, John Dewey, or other persons called «pragmatists». The descriptions of definitions tend to be oversimplifications and caricatures. They are apt to secure easy victories over real or fancied opponents and to entertain, but not instruct, the readers. On the other hand, a philosopher like William James lavishly produced definitoid formulations, many having more literary than scientific value. It is in such cases the function of the serious analyst to compare the various formulations with one another and to concentrate on those that seem to be most precise and representative of James's intentions.

*B. Analysis of Complex Definitoid Statements and Groups
of Definitoid Statements*

**V.8. Inconsistencies and Contradictions Within
Complex Definitoid Statements**

Let us go back to formulations such as «*a*» means (or shall mean) the same as «*b*» and «*a*» means (or shall mean) *b*. They have been called synonymy sentences, interpretative sentences, synonymy announcement sentences, and interpretative announcement sentences. The expression «*b*»—the definiens expression—is often rather complicated. Suppose a definiens expression can be brought into the form «*x* is a K_1 and *x* is a K_2 and . . . , and *x* is a K_n » The expressions « K_1 », « K_2 », . . . , « K_n » are called «conceptual characteristic expressions» of a concept '*b*' expressed in the sentence «*x* is a *b*» (cf. chapter I, page 80).⁴

Sentences of the forms «*a*» means the same as « K_1 and K_2 & . . . & K_n » and «*a*» means « K_1 and K_2 & . . . & K_n », in which *a*, K_1 , K_2 , . . . are designations, are often discussed under such names as «analytical definitions», «material definitions», and «analysis of terms».

One of the chief aims of logical analysis has been said to be to find out whether a concept contains contradictions. In terms already introduced, this question can be said to refer to possible pairs of inconsistent conceptual characteristics.

Except in the most highly developed fields of the exact sciences, complex definiens formulations are usually capable of a variety of highly different plausible interpretations. Suppose K_1 to K_n are each capable of *m* important mutually independent plausible interpretations. This results in a great number of possibilities even if *n* and *m* are small numbers. Thus, if *n* = 3 and *m* = 4, there are $4^3 = 64$ possible interpretations to take into account. It is, in view of the difficulties encountered, of importance to distinguish, among others, between assertions expressed by T_1 – T_4 :

- T_0 : The complex definiens *b* contains inconsistent elements.
- T_1 : For at least one plausible interpretation, «*b*» contains at least one inconsistency.

V. ELEMENTARY ANALYSIS

- T₂: For any plausible interpretation, «b» contains at least one inconsistency.
- T₃: For most plausible interpretations, «b» contains at least one inconsistency.
- T₄: For the most plausible interpretation, «b» contains at least one inconsistency.

These assertions may be intended to be understood in relation to a reference class of interpretations.

In philosophical writings there is a tendency to proclaim that this or that concept is contradictory without mentioning anything about different interpretations being possible and without mentioning which auxiliary hypotheses are constructed to arrive at the conclusion «contradictory». No differentiation between definiens expression «b» and the intended concept, 'b', is made, and likewise «K₁», «K₂» . . . are confused with 'K₁', 'K₂'. . . .

Even a well-established hypothesis that at least one set of interpretations of K_i and K_j results in contradiction does not warrant rejection of the concept involved, as long as there are sets in relation to which the concept is not contradictory. The analyst's verdict according to which the concept «is» inconsistent seems usually to be intended in a rather absolutistic way, namely that there is inconsistency for the (correct) interpretation of the elements of the complex definiens formulations. If this absolutistic verdict were not intended by the analysts, their polemics against the views considered to express contradictions would not be easily understandable. It would be of great interest to the theory of interpretation and preciseness to see such hypotheses about contradictions worked out explicitly and confirmed by methods carefully described.

Commenting on previous drafts of this work, L. Løvestad (1944: 63) points to the great amount of work necessary to work out inconsistencies by comparing all plausible interpretations, and he remarks, «So much brain work may certainly be put to better use though it may be of some significance. To convince us that there is confusion of thought ---, I think it more than enough to show that one set of plausible interpretations makes the definitions contradictory». The moral we draw from this is that instead of pretending to find full-fledged contradictions, we ought normally to limit ourselves to showing *symptoms* of confusion, this being sufficient for many (good

or bad) purposes. If we want to assert something more definite, we may assert that if certain interpretations are correct (in relation to the usage of an author, or a particular public or semantical system, or whatever else), then there is a contradiction. Normally, the diversity of plausible interpretations is so marked, that it does not hold that contradictions are present whatever interpretation is selected. If the level of precization is high, there is a greater chance that the analyst can arrive at reliable conclusions concerning interpretations. The chances of establishing contradictions increase.

The analytical philosopher who proclaims the discovery of a contradiction may seem to think that he discovers a fatal weakness in the works of others, whereas he, at least in my eyes, makes an important concession: he implicitly grants them an unusually high level of preciseness.

The terms «inconsistency» and «contradiction» are used in various senses, and it is not always easy to find out which one is used in a particular context. Roughly, two main directions of precization may be singled out, the one leading to concepts of logical inconsistency and the other leading to concepts of empirical inconsistency. Logical inconsistency may roughly be said to arise when there is a definitional characteristic of 'b' that is the negation of one of the other definitional characteristics, or is derivable from that negation. In other terms, there is logical inconsistency within the system of conceptual characteristics

$$'b' + 'K_1 \& \dots \& K_i \& \dots \& K_j \& \dots K_n'$$

if, and only if, the right-hand side implies a characteristic 'c and not-c'.

«Empirical inconsistency» may be said to exist within the set of conceptual characteristics if the joint attribution of two (or more) of those characteristics to one and the same thing is logically incompatible with assertions that are empirically established. There is no general agreement about what is established empirically: therefore, the claim of inconsistency must be explained in detail.

As an example, let us say that two characteristics, 'made up exclusively of helium' and 'speaks fluent Spanish', belong to the definiens characteristics. The resulting concept may be said to contain an empirical inconsistency in the above sense if we assume that the author holds that gases cannot speak.

V. ELEMENTARY ANALYSIS

In examples of more interest, the inconsistency is more indirect and open to doubt.

Analysis of possible consistency or inconsistency of a definiens concept 'b' can conveniently proceed as follows:

1. A list of plausible interpretations of « K_1 », « K_2 », . . . « K_n », is constructed and the items made precise and standardized in form to such an extent that there is maximum comparability between the interpretations of the various expressions of conceptual characteristics.
2. The precisizations are conceived as logical terms, classes, or properties, and some logical calculi are adopted in relation to which one may decide whether there is contradiction between any subclass of conjunctions of the items or whether a contradiction is derivable from subclasses of conjunctions.
3. Empirical inconsistencies are mapped out on the basis of more or less reliable assumptions of empirical kinds and relating to the empirical opinions of the concept constructors or to a system of opinions adopted because of its importance socially or in terms of competency. All conclusions about empirical inconsistencies will be relative to these sets of premises.

Now, if the complex definiens expressions are highly vague and ambiguous, it is not practicable to proceed as above. In the verdict «contradictory!» there is in our eyes a component of flattery; one concedes that such a high degree of unambiguity has been reached that contradictions have been established beyond reasonable doubt. Only high-level precisizations can be expected to justify the conclusion that there *are*, for all plausible interpretations, inconsistencies. Pieces of rock may collide squarely, but not patches of fog.

V.9. Analysis of Groups of Definitoid Formulations

A central concept in the work of an author is not often defined within definite parts of the work and by means of one single definitional formulation. More often, we find a number of definitional formulations scattered throughout the major parts of the text or heaped up in introductory chap-

ters. It is a difficult job for the elementary analyst to collect the definitoid formulations and to find out on the basis of all of them what the author seems to intend by his basic definiendum formulations, as judged from what he himself explicitly tells us by means of definitoid formulations. The effort is not primarily one of finding inconsistencies, but of using *all* available definitoid formulations as a context in the attempt to make every single one of them more precise, or to find out which of them are most precise.

Among scientists specializing in the nonexact sciences, there are (unhappily) no established mores governing how to indicate what kinds of definitoid formulations are intended. Thus, one formulation may be intended to give a condensed characterization and another a normative definition without this being indicated anywhere. Or, the *author* may consider one formulation of an N-definition the «basic» one that he tries to follow, but that he needs to repeat for didactic purposes. His repetitions are not exact duplications, however, and the *reader* has, often, no means of finding out which formulation is intended to be basic. He is unable to find any information about which measuring rod of several slightly different ones is to be considered the standard.

Even the question of whether two definitoid formulations of one and the same author designate «the same» is often difficult to answer and may call forth somewhat arbitrary decisions.

Usually, more than one expression is classed as definiendum in a text. We speak about «the definitions of Democracy», but concepts of 'Democracy' in the relevant literature are not always expressed by the *one* word «Democracy», but by hosts of more or less synonymous words, for example, «democracy», «popular government», «truly popular government», «truly democratic order», «modern democracy», «democratic state», «more democratic than», and «republican». As analysts we must make up our minds which expressions are to be considered definiendum expressions. If, now, the analyst finds out that the definitions expressed by «a» and «b» are logically contradictory, this conclusion may be premature, because he has not taken into consideration different hypotheses as to which expressions within «a» and «b» must be regarded as definiendum expressions of the same concept. In short, «a» and «b» may have definiendum expressions intended to express different connotations.

Suppose we find that two definitoid formulations, «a» and «b», have

V. ELEMENTARY ANALYSIS

the same definiendum expression or two different but intrapersonally sender- (affirmer- or announcer-) synonymous definienda expressions. A systematic comparison involves, first of all, the following questions:

1. Do the definitoid formulations «a» and «b» belong to the same main subclass of definitions? For example, are they both normative, descriptive, or real definitions? If both are normative definitions, are they both proposals, both decisions, or what?
2. Do both formulations have the same *range of intended application*? If they do not, do they have overlapping ranges? If they have no part in common by definition, do they have something in common empirically?
3. Are the definiens formulations *intended to be strictly synonymous*? Is the one intended to be merely a reproduction of the other, perhaps just to remind the reader of it? Is the one a sort of short reference for the other? Or is the one a sort of definitional precisization of the other? Or is a difference in connotation intended, perhaps in view of the author's having used two slightly different concepts adapted to different purposes?

Until we can answer these sets of questions with reasonable certainty, it is premature to start a profound discussion of conflicting concepts. A conflict presupposes a common area within which there is conflict.

In philosophical literature there is a tendency to ignore the problems that have to be solved before one can conclude, «The two authors both try to define *one and the same* thing, namely ---».

It is common to speak of «the coherence theory of truth», «the pragmatic theory of truth», and so on. We must ask, theories of --- *what*? Protocolation of definitoid formulations referred to as «definitions» or «theories» of truth reveals hundreds of different definiendum expressions. There is not much evidence for the view that a definiendum expression «*die Wahrheit*» or «the Truth» found in a Hegelian or neo-Hegelian text is intrapersonally synonymous with a definiendum expression «a is true» found in contemporaneous texts by empirical philosophers or logicians. The ranges of intended application are scarcely the same, either. Why should

we have discussions on the basis of assumptions that we take here as hypotheses about the same subject matter? If knowledge is the goal, the procedure seems utterly misleading.

If indications of intended range of application are vague or not explicitly mentioned, two definitions said to contradict each other may in fact be compatible, because their intended range of application may not have any point in common. If a term is defined in one way as a *terminus technicus*, it may very well be defined otherwise for use in nontechnical contexts. The definitions are in that case perfectly compatible.

The more a philosopher stresses analytical problems, the more strictly and exhaustively he will have to deal with the matters mentioned in this section. It is not my intention to recommend strictness and exhaustiveness without qualification, but to say, «If you make such and such claims, then you must be able to answer *how* you reached such and such conclusions». But why rely on hypotheses presupposing vast and boring elementary analyses? Perhaps the aims of argumentation might often be reached without pretending that certain such hypotheses were tenable. It is not in the line of this work that such hypotheses should be made.

Within the texts of a single author we may expect a much higher degree of uniformity and consistency in usage than in a group of texts by different authors. The attempt to compare definitoid sentences is made difficult by the complexity of criteria of interpersonal synonymy. Added to this are the particular difficulties arising from the chaotic terminological differences in how words such as «definition» are often used in definitoid sentences.

If the definiendum and the definiens expressions of an author are identical with those of another, this does not imply interpersonal synonymy. Thus, many authors use the same definiens expression in definitoid statements on «democracy», but they would eagerly stress that they do not mean the same by the definiens expression. As an example, we may mention Lincoln's famous formula of «government of the people, by the people, for the people». Theorists from very different camps, Communist authors (for example, Zaslavski in his *La démocratie soviétique*) included, accept the formula as an expression of the definiens, but there is approximate general agreement that, within the different ideological camps, the definiens ex-

V. ELEMENTARY ANALYSIS

pression expresses different concepts. This general agreement may prove more or less illusory—owing partly to the tendency to stress divergencies for propagandistic reasons, partly to different terminology—but fairly reliable judgments in these matters have not, so far, been possible. There is simply no empirical basis, and no theoretical tools, for stating precise hypotheses in the field.

Incidentally, it may be mentioned that Lincoln, whose formula is widely used as a definiens expression of «democracy», rarely used the word «democracy» in his speeches.⁵ The famous passage in his Gettysburg Address (1863) containing the formula reads, «--- It is rather for us to be here dedicated to the great task remaining before us—that from these honored dead we take increased devotion—and that government of the people, by the people, for the people, shall not perish from the earth». Extensive discussions on «Lincoln's definition (or concept) of democracy» have been carried out on the basis of rather weak criteria of identity of N- or Ds-definitions (cf. chapter 4, section 5).⁶ Lincoln uses no definiendum expression that is probably synonymous with «democracy» as used by adherents of the Lincoln formula. Against the contention that weak criteria of identity are being used, it may be objected with some justification, I think, that it is not clear that the participants in the discussion intend to discuss something closely similar to N- or Ds-definitions, even when words such as «definition» and «concept» are used. These words seem to carry rather different meanings among different groups of theorists—as already mentioned. The objection is difficult to refute, but also difficult to confirm. We should still hold that some participants intend by «definition by Lincoln» something sufficiently similar to an N- or Ds-definition to warrant my contention.

V.10. Illustration 1: Bryce on 'Democracy'

Specialists in political science, constitutional history, and other fields in which the word «democracy» and closely related words are used in technical senses offer N-, Ds-, and R-formulations generally consisting of about twenty to forty words. Most of the words in the definiens expressions are taken from the vocabulary of everyday life and from ideological propaganda. The resulting definitoid formulations are difficult to use other than in a loose manner. In this section we shall not exemplify the difficulties of

use, but rather the preliminary difficulties that arise when we try to answer a humbler question, What does the theorist P in his texts on «democracy» *intend to assert* about what he means or intends to mean by «democracy»?

James Bryce, recognized as an eminent analyst of concepts of «democracy», was also an influential ideologist. In the following, we shall study his parallel formulations. Not all of Bryce's texts are subjected to analysis. We limit ourselves to his *Modern Democracies*, vols. I, II (1921), and *The American Commonwealth*, vols. I, II, III (1888). In the works mentioned, at least ten formulations may be classed as definitoid statements. In addition, there are a host of formulations that give important reflections on the use of the word «democracy» (and a group of synonyms or near-synonyms) without seemingly having pretensions to contain complete conceptual determinations.

*a. List of Bryce's Definitoid Formulations on «Democracy»
in Modern Democracies and The American Commonwealth*

1. «. . . Democracy really means nothing more nor less than the rule of the whole people expressing their sovereign will by their votes» (1921: I:viii).
2. «The word Democracy has been used since the time of Herodotus to denote that form of government in which the ruling power of a State is legally vested, not in any particular class or classes, but in the members of the community as a whole. This means, in communities which act by voting, that rule belongs to the majority, as no other method has been found for determining peaceably and legally what is to be deemed the will of a community which is not unanimous. Usage has made this the accepted sense of the term, and usage is the safest guide in the employment of words» (ibid.).
3. «Democracy, as the rule of the Many, was by the Greeks opposed to Monarchy, which is the rule of One, . . .» (ibid., p. 23).
4. «Thus it [Democracy] came to be taken as denoting in practice that form of government in which the poorer class, always the more numerous, did in fact rule; . . .» (ibid.).
5. «. . . it is better to employ the word [Democracy] as meaning neither more nor less than the Rule of the Majority, the «classes and masses» of the whole people being taken together» (ibid.).

V. ELEMENTARY ANALYSIS

6. «Where the will of the whole people prevails in all important matters, even if it has some retarding influences to overcome, or is legally required to act for some purposes in some specially provided manner, that may be called a Democracy» (Bryce 1921: 25).
7. «In this book I use the word in its old and strict sense, as denoting a government in which the will of the majority of qualified citizens rules, taking the qualified citizens to constitute the great bulk of the inhabitants, say, roughly, at least three-fourths, so that the physical force of the citizens coincides (broadly speaking) with their voting power» (ibid., p. 26).
8. «An Ideal Democracy—the expression comes from Plato’s remark that a pattern of the perfect State is perhaps stored up somewhere in heaven—may be taken to mean a community in which the sense of public duty and an altruistic spirit fill the minds and direct the wills of the large majority of the citizens, so that the Average Citizen stands on the level of him whom we sometimes meet and describe as the Model Citizen» (ibid., p. 53).
9. «The word democracy is often used to mean a spirit or tendency, sometimes the spirit of revolution, sometimes the spirit of equality» (1906: 3:323).
10. «For our present purpose it is better to take it [the word «democracy»] as denoting simply a form of government, that in which the numerical majority rules, deciding questions of state by the votes, either directly, as in the ancient republics, or mediately, as in modern representative government, of the body of citizens, the citizens being if not the whole, at least a very large proportion of the adult males» (ibid.).

As a first task of multiple-definition analysis, we shall attempt to classify the formulations in relation to the distinction among N-, Ds-, and R-formulations. The tentative results are indicated in table 1. This classification is highly hypothetical. Of the hypotheses of interpersonal synonymy made use of, the following one is typical: «the word «denote» in the definitoid formulations of J. Bryce is interpersonally synonymous with the word «connote» in the present work».

Some of the definitoid statements may be intended to be definitions

Table 1. Classification of Bryce's Definitoid Formulations on «Democracy»

Definitoid- Statement No.	Definiendum	Subclass of Definition	Field of Intended Application
1	Democracy	Ds	All (most?) occurrences since Herodotus?
2	Democracy	Ds	All (most) occurrences since Herodotus?
3	Democracy	Ds and R?	Ancient Greek occurrences
4	Democracy	N?	A subclass of ancient Greek occurrences?
5	Democracy	N?	Universally?
6	Democracy	Ds	Universally?
7	Democracy	N and Ds? Ds	Occurrences in Bryce's <i>Modern Democracies</i>
8	Ideal democracy	N?	? 1) Universally, or ? 2) No. 8 is a plausible interpretation, or ? 3) No. 8 is sometimes the most plausible interpretation
9	Democracy	None?	Some occurrences (indefinite)
10	Democracy	N?	Texts having the purpose of Bryce's <i>The Amer. Commonwealth</i>

with complex function (see chapter 4, section 13). This is alluded to in the table. Definitoid Statement No. 9 is a hypothesis about usage that can be brought into the form «There exist occurrences of «a» such that «a» means the same as «b»; there exist occurrences of «a» such that «a» means the same as «c»; and so on». It is very difficult to test the hypotheses empirically if there are great numbers of occurrences of the definiendum. For this and other reasons, the concept of descriptive definition has not been made to cover the «existence hypotheses» about usage. They are classed as dictionary definitions, which, in the adopted terminology, are not a subclass of descriptive definitions.

The listed indications of «field of intended application» in terms of occurrences are still more hypothetical. As quoted in Statement No. 2, Bryce says, «The word Democracy has been used since the time of Herodotus to denote ---». It is not reasonable to infer that this expression is meant to be

V. ELEMENTARY ANALYSIS

synonymous with «The word Democracy has been used since the time of Herodotus to connote *one and only* one connotation, namely that expressible by ---». It is not reasonable because it is too obviously untenable to be intended by Bryce. Further, if Statement No. 4 is classed adequately, Bryce is of the opinion that «democracy» in Greece sometimes referred to the rule of the poor, and if Statement No. 9 is classed adequately, the term has sometimes referred to the spirit of revolution or of equality. It is reasonable to suppose that the occurrences that Bryce has here in mind are not occurrences that he thinks represent usage No. 2. It is difficult to avoid inconsistency between No. 2 and Nos. 4 and 9 if «has been used since the time of Herodotus» in No. 2 is interpreted to mean the same as «has always been used since the time of Herodotus».

Definitoid Statement No. 7 is classed as a descriptive definition, but as indicated in the table, it may also be interpreted as a combined N- and Ds-definition. In support of the latter indication we can reason as follows: When an author tells us, in the opening sections of a book, and after having discussed various possibilities of definition, that he *uses* a term in a special way in that book, he may thereby intend to convey to the reader a decision about how to use the word in that book. Suppose the reader finds an occurrence later in the book that cannot be subsumed (he thinks) under the definiens indicated by the author, and suppose the author agrees about the insubsumability. It is in that case plausible that the author will reformulate his occurrence sentence rather than his definitoid sentence. This would be a curious way to straighten things out if the definitoid sentence were meant as a purely descriptive definition, but a reasonable way if the sentence were meant to have a normative function. The author would then reformulate in order to follow his decision expressed by the definitoid sentence conceived as a combined descriptive and normative definition.

We might quote passages indicating that Bryce attaches particular importance to a sense intended to be expressed by No. 2, No. 1, and No. 7. The wordings of No. 1 and No. 7 are themselves indications of this. The problems involved are of practical importance in contemporary ideological conflicts. Authors contending that Marxists misuse the word «democracy», and Marxists contending that their critics misuse the same word, all seem to rely more or less on statements of experts like Bryce, even in cases where the definitoid formulations are astonishingly vague and ambiguous as regards intended range of application.

Turning to the question of *synonymity among the various definiens expressions* indicated more or less precisely by the ten statements, we shall at first limit ourselves to a rough answer. The ten definiens formulations fall into four heteronymous groups, one consisting of the definiens formulations of Nos. 1, 2, 3, 5, 6, 7, 10, one consisting of No. 4, one consisting of No. 8, and one consisting of No. 9. It is probable that No. 8 has to be disregarded because there is rather strong evidence that it is defining «something else» than the other formulations, even if we use a rather broad concept of identity of definitions.

The main group of definiens formulations are possibly meant to express or suggest one and the same concept. Which concept? That question leads us to the construction of lists of plausible interpretations. Before we attack that question, however, some slight reformulations are suggested with the aim of making the statements easier to compare with one another and with similar formulations of other authors.

b. Reformulation of Some Definiens Expressions to Facilitate Comparison and Increase the Level of Preciseness

The following reformulations are made on the basis of a context comprising the ten statements plus comments, some of which may be meant as definitional, found in the texts of Bryce.

Statement No. 1

From No. 2, I infer that Bryce means to speak about forms of government of *states*. In No. 3, Monarchy is spoken about as the opposite of Democracy. Monarchies usually are classed as states. This also suggests that the «government» alluded to in No. 1 are state governments.

The reference to «sovereign will» might be interpreted in a way that made the existence of a sovereign will a presupposition of the author of the statement. Or it may be interpreted to indicate that one of the requirements of a state government's being democratic is that the will of the people should be sovereign. There are other interpretations that seem just as plausible. Here is a single, very tentative definiens reformulation:

(01.1) A state ruled by the whole people by means of the technique of voting and in such a way that their will is sovereign.

V. ELEMENTARY ANALYSIS

Statement No. 2

In view of No. 5, No. 7, and No. 10, reference to the «will of the majority» seems to be meant as part of the definition. No. 9 uses the even more precise term «numerical majority». If there is an important state issue on which a majority cannot be constructed by any known means, the definition does not apply. If there are regularly no majority decisions, the state government probably cannot be called democratic in the sense discussed. In view of the extensively debated questions turning up here, I shall construct several reformulations that are more or less plausible interpretations of the definiens of Statement No. 2.

(02.1) A state with a form of government in which the ruling power is legally vested in the members of the community as a whole.

(02.2) A state with a form of government such that the ruling power belongs in practice to the majority of the members of the community as a whole, the members acting by vote.

(02.3) A state with a form of government such that the ruling power is legally vested in the majority of the members of the community, the members acting by vote.

Statement No. 5

Statement No. 5 is probably a deprecization used for the sake of short reference. «Rule» may be taken to refer to the form of government, to the practice of government, to both, or to the disjunction.

Statement No. 6

Taking into account the reference to majority and to other factors, we venture to set forth the following sentences as plausible interpretations:

(06.1) Where the will of the people prevails in all important matters.

(06.2) Where the will of the majority prevails in all important matters.

Statement No. 7

For Statement No. 7, we suggest the following reformulation:

(07.1) A form of government by which the will of the majority of the qualified citizens rules, the class of qualified citizens being

delimited in such a way that roughly at least three-fourths of the inhabitants are included in the class.

Statement No. 8

It is not clear whether Bryce means to accept a concept of 'Ideal Democracy'. The following reformulations are suggested:

(08.1) A community in which the sense of public duty and an altruistic spirit fill the minds and direct the wills of the large majority of the citizens.

(08.2) A community in which the Average Citizen stands on the level of him whom we sometimes meet and describe as the Model Citizen.

Maybe Statement No. 8 ought to be interpreted as stating what would be the ideal (best conceivable) state of affairs within a democracy. In that case, it should not be included in any list of definitions.

Statement No. 10

The following reformulations seem to us plausible interpretations of the definiens of Statement No. 10:

(10.1) A form of government in which the numerical majority of citizens decides questions of state by vote, the class of citizens being delimited in such a way that it comprises all adult males or at least a very large proportion of them.

(10.2) A form of government in which the numerical majority of citizens rules. Insofar as the rule consists in making decisions in relation to questions of state, the majority decides by the votes, directly or mediately. All adult males, or at least a very large proportion of them, are considered to be citizens.

The reformulations have been made primarily to illustrate the activity of reformulating definitoid statements. There are many other reformulations that might be of interest in special situations. Thus, if Bryce's definitions are to be compared with those of another theorist, reformulations are needed that increase the similarity of *intentional structure* of the concepts compared.

V. ELEMENTARY ANALYSIS

If we are asked *which* concept of Democracy Bryce uses, we should have to answer that there are differences in formulations that make different interpretations possible, the differences being large enough to exclude fairly precise formulations. The majority of his definitoid statements suggest that he intends concepts of constitutional democracy, a subdivision of the class of concepts of political democracy.

c. Tentative Precizations of Bryce's Definitoid Formulations

The reformulations proposed above are precizations for *me*. They need not, of course, be precizations for others, but I expect that some of them will be. Some of them, I think, Bryce would have acknowledged as precizations for him; others, he would presumably have classed as misunderstandings. We try to exemplify the construction of tentative lists of precization based primarily on study of definitoid formulations, not of formulations of usage. In the last part of this chapter, and in later chapters, the study of usage in the sense of study of *all* occurrences of an expression is made our subject of description.

Our first direction of precization is one that may vaguely be indicated by the following questions: Are, *per definitionem*, states, and no other things, democratic, or can clubs, manners, individuals, and distribution of goods be democratic? Can some of the combinations (or/and combinations) be democratic?

It should be stressed at the very beginning of these attempts at precization that we ask about what can be democratic by N-definition or Ds-definition. Which are the *conceptual characteristics* (*Begriffsmerkmale*), if any, that refer to states, clubs, and so on, as being democratic? It is perfectly possible to use the expression «democratic manners» even if a concept of 'state democracy' is adhered to and *concepts* of 'democratic manners' are explicitly rejected. The expression may be precized into «manners (empirically) typical of democratic states». If one such democratic manner is to wear green trousers, it is perfectly consistent with concepts of 'democracy' as something by definition applying only to states, to speak of «democratic trousers», meaning, for example, «trousers used only in (state) democracies».

The old distinction between conceptual and other characteristics may sometimes be difficult to apply and sometimes unfruitful in application,

but on the whole I think it is of great practical and theoretical value. The distinction is explicitly mentioned in this connection because it is often slurred over in dictionaries and encyclopedias.

In Statement No. 2, Bryce refers to states: «form of government in which the ruling power of a *state* ---». He also refers to «states» in No. 9. No expression in any of the formulations seems to provide strong arguments against the assumption that democracies are, by N- or Ds-definition, states according to Bryce. But what does «state» mean here? Does the word include federations of states, as for example, that of the United States in 1800? What about the United States in 1900? From the use of the word «state» in Bryce's *Modern Democracies*, it would seem that both the United States as a totality and its individual states are «states» in Bryce's sense. Would Bryce have called the Ukrainian Soviet Socialist Republic a state? Or the Estonian Soviet Socialist Republic? From the definitoid statements and commentaries to these statements, it is difficult to judge. In any case we tentatively put forth the following genus proximum precization:

T₁: A form of state government, or a form of federation of state governments.

What is meant by a «*form* of government»? Mostly I have interpreted Bryce to mean something like «government as legally determined by constitutions and other kinds of legal documents». But maybe something similar to «kind of government» is meant. This brings us to the next direction of precization to be considered: Is «government» to be taken in a broad sense of «rule»—covering not only legal institutions but also the whole political «life»? Is «government» to be understood as something like «making and carrying out decisions of state», or is it mainly the «making» that is involved? Or is «government» to be understood in narrow senses, as in phrases such as «the government obtained a vote of confidence» and «the government has changed twice this year»? Is «government» to be thought of as «ruling *power*» in such senses that make it plausible to state that «the people govern»? In the sphere of legislation, is to govern to make laws—as is done, for example, by legislatures—or to be the source of law? (Compare John Austin's view of sovereignty as source of law [1875].) Does government include local government? the courts? the activities of price-regulation institutions? Is «government from day to day» involved, or only

V. ELEMENTARY ANALYSIS

«ultimate basis of long-run influence»? In the former alternative, what is meant by saying that a state *is* democratic—does this imply «is always» something like «in times of war, or threats of war, --- may be excluded»?

It is not our aim to point out how many factors of importance to high levels of preciseness are left unmentioned in Bryce's definitoid formulations. He has himself warned against pretensions of constructing formulas that are precise enough to make classification into democracies and non-democracies possible in *all* cases. He touches on the questions of the direction of precisization now being mentioned in the following words: «There are countries in which the Constitution has a popular quality in respect to form, but in which the mass of the people do not in fact exercise the powers they possess on paper». --- «It is the facts that matter, not the name». «[T]hough we cannot define either Oligarchy or Democracy, we can usually know either the one or the other when we see it» (Bryce 1921: 1:25). After this sentence comes definitoid Statement No. 6, which is the one containing the most explicit reference to actual influence on decisions rather than legally vested influence. Also, Nos. 1, 3, 5, and 10 seem to point to broad interpretations of «government».

Each of the following formulations seems to me to be a plausible interpretation of at least one of the statements depicting the use of «democracy» as proposed by Bryce:

(1.1) «S is a democracy» means (according to Bryce's N-definitions) the same as:

- «1. S is a state or federation of states, and
2. S has a written or unwritten constitution providing the legal basis of institutions of such a kind that they, if the provisions of the constitutions were followed, would guarantee that important decisions of state were made in accordance with the will of the people, and
3. Except in grave cases of emergency or possibly even then, important decisions of state are in S made in accordance with the will of the people».

(1.2) «S is a democracy» means --- : «1.--- and 2.---».

(1.3) «S is a democracy» means --- : «1.--- and 3.---».

(1.4) «S is a democracy» means --- : «1.--- and 2.--- or 3.---»

Statement No. 2, perhaps Bryce's most influential definitoid statement, as judged by frequency of quotation, lends itself well to precizations in the direction of (1.2). Taking all the definitoid statements as context, this direction seems to me to be the least plausible. There are, however, no reasons to reject the practical possibility of (1.2) being intended by some of the definitoid formulations (but not by all). In those cases, requirement 3 may be looked on not as a conceptual characteristic, but as a criterion of «real», «strict», or «good» democracies, meaning thereby to indicate a subclass of democracies approved of somehow.

Statement No. 6 may plausibly be interpreted in the direction of (1.3) or (1.4). When all the definitoid statements are taken into account, the plausibility turns more toward (1.1), however.

Considering all the statements together, I consider (1.1) to be the most plausible interpretation of the four listed. This conclusion, as well as the whole approach, is highly speculative in the sense that we do not try to collect detailed evidence. The argumentation is loose and as stated here very sketchy. These critical remarks have as a basis certain norms about adequacy of evidence, argumentation, and exposition that are more rigorous than those that seem to be generally adopted, however.

In the tentative partial precizations (1.1)–(1.4), some very obscure expressions are still left unprecized, for example, «will of the people», «important decisions of state». These expressions are left untouched because they are convenient point-of-departure expressions for new directions of precization. Let us take the expression «the people». Precization of this ideologically important word gives us perhaps the most profitable direction of precization from the point of view of elimination of pseudoagreements, which is of practical importance in contemporary ideological controversies.

Who are «the people» mentioned in the definitoid statements? Bryce has himself precized the expression to some degree. Here are some expressions used in his definitoid formulations:

- U: the people
- U₁: the whole people (see Statements No. 1 and 6)
- U₂: the members of the community as a whole (No. 2)
- U₃: the Many (No. 3)

V. ELEMENTARY ANALYSIS

- U₄: the Majority (? No. 5)
- U₅: the «classes and masses» of the whole people being taken together (? No. 5)
- U₆: the inhabitants (? No. 7)
- U₇: the great bulk of the inhabitants (? No. 7)
- U₈: the qualified citizens (? No. 7)
- U₉: the majority of qualified citizens (? No. 7)
- U₁₀: the citizens (? No. 10)
- U₁₁: if not the whole, at least a very large proportion of the adult males (? No. 10)

We have in the cases of Statements No. 5, 7, and 10 indicated by question marks that we are undecided as regards which, if any, expressions in these formulations correspond to the expression «the whole people» in Statement No. 1. In the reformulations on page 253, the catchphrase «will of the people» is used. That use can now be avoided.

Each of the following formulations seems to me to be a plausible interpretation of at least one of those statements that may be meant as N-definitions:

(2.1) «S is a democracy» means (according to Bryce's N-definitions) the same as:

- «1. S is a state or federation of states.
- 2. The source of power to decide questions of state is in S legally vested in the whole body of qualified citizens.
- 3. The qualified citizens comprise legally all or at least a very large proportion of the adult male inhabitants of S.
- 4. The decisions are in S legally made by majority vote among the qualified citizens, directly or indirectly».

(2.2) «S is a democracy» means (---) the same as:

- «1. S is a state or federation of states.
- 2. The power to decide questions of state in S is in practice in the hands of the whole body of qualified citizens.
- 3. The qualified citizens include all or at least a very large proportion of the adult male inhabitants of S.
- 4. The decisions are in S made by majority vote among the qualified citizens, directly or indirectly».

(2.3) Identical to (2.2) except for conceptual characteristic 4, which runs as follows:

4. Questions of state are in S decided in accordance with the decisions that would have been made, provided the citizens had made the decisions by majority vote.

(2.4) Identical to (2.2) except for the fourth requirement, which runs as follows:

4. Questions of state are in S decided, directly or indirectly, by the qualified citizens.

Many additional plausible interpretations may be formulated by combining these four, by leaving out stated requirements, or by combining the resulting broader concepts. We shall limit ourselves to mentioning some of fairly high relevance to contemporary controversies.

Requirement 4 in (2.1) and (2.2) is difficult (if plausibly interpreted) when a voting group splits in such a way that no proposal attracts as much as 50 percent of the vote. Bryce explicitly justifies the «majority» clauses in his definitions by saying that no other method has been found to determine «peaceably and legally what is to be deemed the will of a community which is not unanimous» (Bryce 1921: 1:23). These two factors point toward the possibility of leaving requirement 4 out of the definition. This would make it possible to leave out complicated references to governmental machinery within precisizations of (2.1) and (2.2).

Someone may object that strong precisization ultimately would have to mention concrete procedures of voting. Such an objection, however, implies a misconception of the procedures of definition. We may strongly precisize what in the theory of patent-claim drafting is called a «function» or «effect» as contrasted with the structure (devices) of machinery, and give a highly operational definition of function in terms of effects, without answering questions of how the effects are produced beyond certain links in cause-effect chains that are very close to the effects.

The phrase «source of power» («sovereignty» in some interpretations of this word) is a weak spot in the wording of requirement 2. Further steps of precisization might conveniently use negative phrases, such as «No group of the inhabitants is excluded from performing certain acts of influencing state decisions on account of race, income, property, sex, political opinion, ---».

Concept (2.3) may lead to the inclusion of state governments such as

V. ELEMENTARY ANALYSIS

that of Napoleon III, or even of Hitler, among democracies. The «will of the people» may in some sense «prevail» under authoritarian governments, just as authoritarian parents may let their children have their way.

The interests (needs and desires) of the populace are not referred to in any of Bryce's definitoid statements. It may be a tacit assumption that the «will of the people» announces the interests of the people (for example, that the people are not deceived so as to vote against their interest or vote against it because of lack of insight). In contemporary discussions there is much talk about what determines the «will of the people» if that will is identified with certain answers put before the citizens or their representatives by powerful organizations and institutions.

There are many directions other than the three mentioned in which «democracy» may be precized. Bryce's definitoid statements do not contain much material, however, that could be used as evidence for or against hypotheses of interpretations in those directions. We shall therefore leave the subject.

A low level of preciseness may have been sufficient for Bryce's purposes. He is primarily interested in studying and describing the political institutions of France, Switzerland, Canada, the United States, Australia, and New Zealand, and he is especially concerned with certain common trends and patterns in the development of those states. He is only secondarily interested in a broad classification adapted to detailed comparisons of a great number of states. Just as a physiologist of certain plant genera may have little use for the niceties of the plant classifier, so the student of certain intimate functions of a handful of modern states may not need to use highly sophisticated tools of a systematic classification of states, past and present.

The quotations and discussions of this section are part of the material necessary to give an exact answer to an inexact question, *What does Bryce say he means by the word «democracy»?* The answer may be an undigested list of quotations—a very bad answer. Or we may comment on them, saying that this or that formulation probably does not—for the reader—give as good an expression of Bryce's intention as this other formulation.

For many purposes, it is valuable to try to find one particular formulation especially adapted to the title «a fairly precise formulation of the sense James Bryce says he gives the word «democracy»». Here is a candidate:

A state or federation of states, S, satisfying the following requirements:

1. S has a written or unwritten constitution providing the legal basis of institutions of such a kind that, if the norms of the constitution were followed, it would guarantee that the source of power to decide questions of state would be in the hands of the whole body of qualified citizens.
2. The norms of the constitution of S are followed.
3. From the delimitation of 'qualified citizens', as prescribed by the constitution or other legal documents, it follows that under all practically conceivable circumstances, all, or at least a very large proportion, of the adult male inhabitants of S will be qualified citizens.
4. The legal delimitation of 'qualified citizens' is followed in practice in S.
5. Except in grave cases of emergency, or possibly even then, important decisions of state are in S according to law, only if made by majority vote among the qualified citizens, directly or indirectly.
6. The legally prescribed procedure of voting is followed in S.

A considerably shorter formula is: «democracy» connotes for James Bryce a form of government and government practice whereby at least three-fourths of the adult males have voting power and in which this power gives the majority of the voters or the majority of their chosen delegates power to decide basic questions of policy.

A question not discussed here is, How does Bryce actually *use* the word «democracy»? An answer involves study of subsumption of instances under general rules, a subject treated in the last part of this chapter and in later chapters. So far, our concern has been the definitoid statements on use, not the use itself.

We have singled out the word «democracy» and the author Bryce in order to give an illustration of analysis of groups of definitions. The choice has brought to the fore problems of analysis that are neither unusually difficult nor unusually easy. Bryce is regarded as a man of extraordinary clearness of thought and expression, and an analysis of «democracy» as expressing forms of government does not present special difficulties. In spite of this, a great many difficult questions are presupposed solved by anyone who, without restrictions and with scientific pretensions, says, «*This* is what Bryce says he means by «democracy»: ---». Even more is presupposed

if we say, «Between the concept of ‘democracy’ adopted by Bryce, and that adopted by Laski, there is the following difference: ---», or «The concept of ‘democracy’ adopted by Bryce is inconsistent».

V.11. Illustration 2: Bradley on «Truth»

In this section we propose to leave the analysis to the reader. A list of formulations is presented, the author of which is the well-known English philosopher Francis Herbert Bradley.

If these are formulations of definitions, how are they related to one another? How are they related to a D-formulation such as «truth means agreement with reality»? Is «truth» in that formulation meant to connote the same as «truth» in Bradley’s formulation? Or perhaps one has to distinguish «truth» as a collective name for «truth», and «truth» as an all-comprehensive unique system? How, in that case, is the discussion between Bradley and the pragmatists to be understood? How is the definiendum «truth» to be related to the definiendum «true» in the works of Alfred Tarski?

We mention these questions to invite the reader to formulate problems presupposing the kind of elementary analysis dealt with in this paper. Here are some of the formulations representing the object of study, all of them direct quotations from Bradley (1914).

1. «The identity of truth, knowledge and reality, whatever difficulty that may bring, must be taken as necessary and fundamental» (p. 113).
2. «--- truth, if it were satisfied itself, and if for itself it were perfect, would be itself in the fullest sense the entire and absolute Universe» (p. 113).
3. «Truth claimed identity with an individual and all-inclusive whole. But such a whole, when we examine it, we find itself to be the Universe and all reality» (p. 116).
4. «Truth is the whole Universe realizing itself in one aspect. --- And those aspects in which truth itself is defective are precisely those which make the difference between truth and reality» (p. 116).
5. «Truth is an ideal expression of the Universe, at once coherent and comprehensive. It must not conflict with itself, and there must be no suggestion which fails to fall inside it» (p. 223).

6. «To gain truth the condition of the predicate must be stated ideally and must be included within the subject. This is the goal of ideal truth, a goal at which truth never arrives completely.»
7. «--- truth is identical with Reality in the sense that, in order to perfect itself, it would have to become reality. On the other side truth, while it is truth, differs from Reality, and, if it ceased to be different, would cease to be true. But how in detail this is possible cannot be understood» (p. 343).
8. «For me truth gives the absolute Reality, the whole Universe as in its general character it really is» (p. 351).

V.12. Metaoccurrence Analysis in General

Definitoid sentences make up an important subclass of sentences that say something about «use», «interpretation», «meaning», and so forth, of sentences or designations. The importance of the definitoid sentences lies in the broadness of their claim: they seem to furnish a complete indication of how an expression is (or shall be) used or a condensed description of all possible denotata.

Metaoccurrences may also contribute to our knowledge, even if they do not have such a broad claim. Their analysis may therefore be of importance, especially in the case of authors whose terminology is difficult to understand because they have not provided any normative definitions.

Our first example of a nondefinitoid metaoccurrence comes from Pericles' *Funeral Oration*, 431 B.C. «It is true that our government is called a democracy, because its administration is in the hands, not of the few, but of the many» (Thucydides, trans. C. F. Smith 1921–30: 323).

Here is another example. «By «predicates» I [Quine] mean, not properties (or classes) and relations, but merely certain notational expressions» (Quine 1945: 1). Quine gives what is, in this work, called a genus definition («predicate» stands for members of a subclass of notational expressions, a genus of notational expressions).

Richard von Mises (1939: 7) proposes the terminological convention «dass wir im folgenden unter einem Wort, einem Satz, einem Text immer nur ein in der Schrift festgehaltenes Bild verstecken». He wishes differences in pronunciation by different people to be ignored, along with certain other differences that are not indicated in writing. It is scarcely his inten-

V. ELEMENTARY ANALYSIS

tion to give a normative interpretative definition of the kind «By «sentence» shall be meant picture of sentence as part of written text». Maybe he intended to offer such a definition, but his statement may at least plausibly be interpreted as offering a piece of information about proposed usage without the pretensions of a normative definition.

As another example of a metaoccurrence that may be important for adequate interpretation of a term, but that does not furnish a normative or descriptive definition, we may quote a statement of Carnap's: «--- in the book under discussion, I do not apply the term «proposition» to sentences or to any other expressions» (Carnap 1945: 154). This hypothesis about one's usage is not a descriptive definition, but in a metaoccurrence analysis of the term «proposition» the statement may be of value to the analyst.

C. Subsumption Analysis

V.13. Scope and Definition of Subsumption Analysis

Whenever there is a problem of testing whether anything conforms to a given characterization, whether or not it is an instance of something having a described property, one may speak of a problem of *subsuming* an instance under a characterization or rule. Classification and exemplification involve subsumption thus conceived.⁷

In this work a narrower concept is more useful, but let us, as a preliminary, consider some of the features of subsumption, taking the term in its wide and vague connotations.

In relation to any doctrine whatsoever, one may ask, What are the signs of its tenability? of its untenability? What are the limits of irrelevancy? Subsumption under such categories presupposes that the doctrines are somehow expressed and that the expressions satisfy requirements of preciseness. «Tenability» must be given a definitional precization, and all alleged evidence for or against must, if put forth seriously, be expressed in such a way that the subsumability hypotheses can be judged. It is now generally conceded that there is no *experimentum crucis* for this: a mass of observations may be taken to establish tenability only if various kinds of auxiliary hypotheses are employed. These auxiliary hypotheses may always be formulated as subsumability hypotheses—hypotheses that, together with certain data, make the

data subsumable under a characteristic. The auxiliary hypotheses justify these data being judged relevant as positive evidence of something.

In courts, and in jurisprudence in general, subsumability hypotheses are often expressly and lengthily discussed: Is this or that law applicable? Is this or that action subsumable under the rules of competency set up for this or that institution? Often, the expression «to interpret» is, in jurisprudence and administration, used in such a way that subsumption of concrete instances under general rules is part of the interpretational process.

In social science, the extensive use of questionnaires worked out to obtain evidence for or against hypotheses has made it necessary to rely on the codification of answers. Systems of auxiliary hypotheses must be mentioned in order to make explicit how the researchers are able to class certain answers as more or less strongly positive evidence, and certain others as more or less strongly negative evidence.

Lack of explicitness in explaining subsumptions makes the auxiliary hypotheses untestable. If each of two scientists who support rival theories declares that a certain mass of data confirms his own and disconfirms the rival theory, there is not much value in gathering new data. It will first of all be necessary to investigate how the scientists manage to carry out their conflicting subsumptions: what are the main auxiliary hypotheses of each instance of subsumption of evidence?

Every testable assertion about usage, or rules intended to regulate usage, has an intended field of application. Its delimitation may be more or less explicitly formulated or totally unformulated, but if no possibility of subsumption is thought of, the «assertion» makes no claim. Whether one should still call it an «assertion» is open to doubt.

If «a» is a definiendum expression and S the field of application, a normative definition announces something about every instance (occurrence) of «a» within S. It announces a synonymy relation between «a» within S and a definiens expression «b». Further marginal references delimit the usage of «b» that is intended by the sender of the normative definition.

Let us suppose that the sender wishes «b» to be interpreted as the readers of his texts interpret it. Some complications result from such a stipulation. Telling his readers that in his texts «a» shall mean the same as they, the readers, mean by «b», he can only be said to have followed his normative definition if any occurrence a of «a» in the texts is intended to express

V. ELEMENTARY ANALYSIS

the same as «b» expresses for the readers when they substitute «b» for «a». That is, there must be synonymy between a for the sender and b for the readers. In symbols:

$$(i)(j)\text{Syn}(a_i P b_j Q_j)$$

where P is the sender and Q_1, \dots, Q_j, \dots the readers.

The normative definition cannot be followed unless all the readers interpret the definiens expression in the same way. That is, if the normative definition is to be followed, the following condition must hold:

$$(i)(j)(k)(l)\text{Syn}(b_i Q_k b_j Q_l)$$

The analyst charged with the task of testing whether the sender of the text sentences and of the normative definition has or has not followed his normative definition is confronted with various problems. He must find out about the meaning intended by the sender of occurrences $a_1 \dots a_i \dots$, that is, the occurrences of the definiendum expression. Those intended meanings must be compared with the interpretations representing how readers have interpreted $a_1 \dots a_i \dots$. Suppose the readers have interpreted $a_1 \dots a_i \dots$ as they would have interpreted «b» at the same places in the text; that is, they have followed the announcement of the sender. If now their interpretations of «b» as substituted for $a_1 \dots a_i \dots$ coincide with the sender's intended meanings of $a_1 \dots a_i \dots$ then the sender has followed his normative definition. If not, he has violated his stipulations.

This example has been considered in detail because it shows a kind of normative definition that makes consistent application dependent on interpretation processes, not only of the author of the normative definition, but of a group of people that is usually open and of rather indefinite boundaries. Hypotheses of interpersonal synonymy are involved.

V.14. Some Preliminaries Involved in Subsumption Analysis

Schematic Survey

Assertions or announcements relevant to subsumption analysis may be expressed within the following scheme:

Syn(aPS₁, bQS₂) (Ann or Ass)

The symbols «a» and «b» stand for two designations or two formulations. The synonymy hypothesis or synonymy announcement states something about *every occurrence* (instance) of «a» satisfying the requirement that «a» must be «for P in S₁» and every occurrence of «b» satisfying the requirement that «b» must be «for Q in S₂». In other words, occurrences of «a» and «b» are relevant only provided they are denotata of the concepts ‘occurring in S₁ for P’ and ‘occurring in S₂ for Q’. The relevance of the synonymy hypothesis or announcement in relation to any set of occurrences of «a» and «b» depends on the subsumability of «a» under the first concept and «b» under the second. It is not this kind of subsumability, however, that has given subsumption analysis its name.

If a set of occurrences of «a» and «b» is subsumable under the concepts mentioned, a *synonymy hypothesis* of the kind

Syn(aPS₁, bQS₂) (Ass)

states that for every such set of «a» and «b» there is a relation that *holds good*, namely ‘synonymy between «a» and «b»’.

If a set of occurrences of «a» and «b» is subsumable under the concepts mentioned, an *announcement* of the kind

Syn(aPS₁, bQS₂) (Ann)

states that for every such set there is a relation that *holds good if the announcement is followed*, namely ‘synonymy between «a» and «b»’.

If, and only if, an occurrence of «a» for P in S₁ is a denotatum of the concept ‘synonymous with «b» for Q in S₂’, then the schematical synonymy hypothesis is confirmed in relation to that occurrence of «a».

We call *subsumption analysis* the inquiry into whether given occurrences of «a» for P in S₁ can be subsumed under the concept ‘synonymous with «b» for Q in S₂’. The aim of that analysis is to find the arguments for and against subsumability and to weigh them against each other.

If we use synonymy concepts by which synonymy is defined operationally as the occurrence of certain types of answers to certain types of questions, subsumability may be easily shown or refuted. Nor-

V. ELEMENTARY ANALYSIS

mally, we use synonymity concepts that are more independent of such questionnaires.

The general scheme of synonymity hypotheses and announcements is unnecessarily abstract and complicated for our discussion of subsumption analysis. We may adapt the terminology of our discussion of definitoid statements to our present purpose and use the terminology indicated below:

Syn(TM, UM') (Ann or Ass)	
T	definiendum expression or expressions (sometimes also used for the class of definiendum expressions)
M	intended field of application of the synonymity hypothesis or announcement
U	definiens expression or expressions
M'	the standard interpretation

Using the terminology of analysis of definitoid statements, we write:

T	expression somehow indicating class of definiendum expressions
M	expression somehow indicating field of intended application
U	expression somehow indicating class of definiens expressions

We use the nonspecific «somehow indicating» so that we may include a great many rather obscure, but important, definitoid formulations found in all kinds of literature. If, for example, we try to determine whether certain usages of «democracy» within certain types of propaganda follow the indications the authors give as determining their use of the word, we shall have to analyze rather obscure indications, not clear-cut synonymity hypotheses or announcements.

By the symbols M_1, M_2, \dots we refer to interpretations of the expression, M, indicating the intended field of application—if there is any such

explicit or implicit indication. For the designatum of M_1 , that is, the field itself, we use M^1 .

By the symbols T_1, T_2, \dots we refer to interpretations of the expression, T , indicating class of definiendum expressions. If several expressions make up the denotata of the class, we write T^1, T^2, \dots .

For example, let T be the expression «the term democracy». Differences of interpretation of that expression owe in part to the habit of taking «democracy» to stand, not only for the English word, but also for various other translations of the corresponding Greek term. The denotata T^1, T^2, T^3, \dots of the class of definiendum expressions are in such cases «democracy», «*démocratie*», «*Demokratei*», and so on.

By the symbols U_1, U_2, \dots we refer to interpretations of the expressions indicating class of definiens expressions.

By these symbolizations we stress the separateness of the series of interpretations of expressions ($M_1, M_2, \dots, T_1, T_2, \dots$) and the series of expressions themselves ($M^1, M^2, \dots, T^1, T^2, \dots$).

If it is asked, «Has the word T the meaning U within context M ?» we may very roughly say that the prevalent technique for finding out whether any particular instance of T within M has the meaning U is to ask, «Does U fit in where T is written?» «Do we get a *good meaning* within the context of that occurrence, when we suppose T is used in the meaning U ?» On the superficial dictionary level it may, for instance, be asked whether «democratic» as used within a certain context means «pertaining to the Democratic party (in the United States)». Within a text we find as occurrence No. 1 «The democratic city states of the ancients did not have many inhabitants». We conclude: this occurrence does not fit in with «pertaining to the Democratic party»; therefore, the word must have some other meaning in this context.

This is only a very rough indication. As soon as we try to formulate more precisely the types of arguments used, and the way they are tested, great difficulties arise—difficulties that, so far, no one has extensively investigated and described.

Figure 3 has been prepared to facilitate the survey of the distinctions introduced in this section. It uses the same model as figures 1 and 2 (pages 221 and 224).

The top portion of figure 3 illustrates how an analyst reads a definitoid

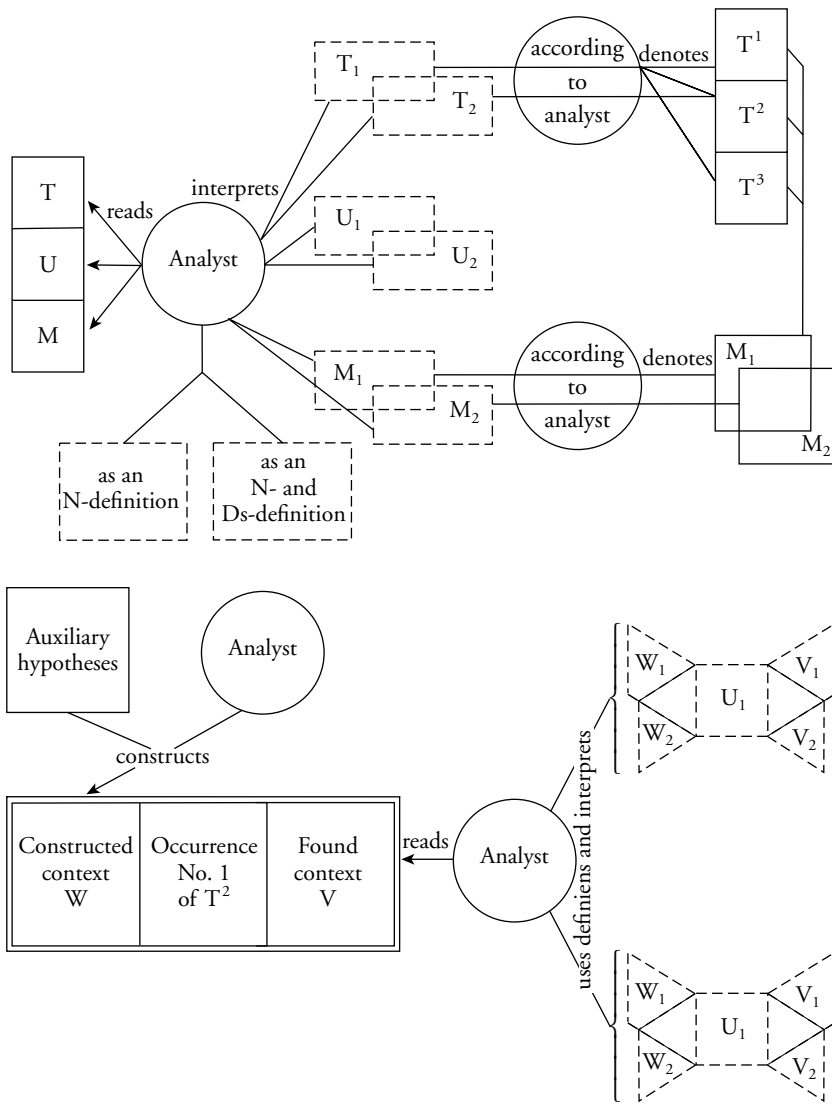

Figure 3. Schematic model for subsumption analysis.

formulation. He interprets the formulation to express either a normative definition or a combined normative and descriptive definition. For the sake of simplicity, M' is left out of the picture. The expression indicating definiendum expressions he interprets in two different ways, T_1 and T_2 . As regards definiens and field of intended application, he likewise cannot limit the interpretation to a single most plausible one, but works with two different interpretations. The definiendum expression denotes, according to the analyst, various expressions. If T_1 is the definiendum interpretation, then T^1 and T^2 are the only denotata. If T_2 is chosen as definiendum interpretation, then T^2 and T^3 are the only denotata within the intended field of application—however this field is interpreted. (This is illustrated by lines from M^1 and M^2 to T^1 , T^2 , and T^3 , indicating that the T 's are part of both M^1 and M^2 .)

In the lower part of the diagram, we have to the left singled out an occurrence (instance) that is to be judged subsumable or not subsumable under the definitoid statement analyzed. It is occurrence No. 1 of the expression T^2 that is to be considered a definiendum expression of the definitoid statement, however T is interpreted. For the sake of simplicity, we assume that T^2 is a formulation, not a designation.⁸ To the right of T^2 is symbolized the verbal context V , which the analyst finds surrounding T^2 . We may think of sentences immediately preceding and following T^2 within a monograph, or we may think of larger context units.

To the left of the rectangle symbolizing occurrence No. 1, we have a rectangle W symbolizing a written «constructed» context of T^2 . By this we mean an exposition of relevant information concerning T^2 , for example, data on the historical epoch in which T^2 probably was written, hypotheses about the political inclinations of its author—in short, anything we use as premises for our interpretation of T^2 except the verbal context V , which simply is «found» as a part of the physical environment of T^2 . The constructed context may normally be thought of as including quotations from various sources that throw light on the use of T^2 . Many of the sentences of the constructed context may be based on intricate, for example, historical, auxiliary hypotheses. These are symbolized by a box above rectangle W .

The analyst approaches the task of subsumption analysis when he reads the sequence WT^2V and interprets T^2 as meaning the same as the definiens, that is, U_1 or U_2 . Doing this, he may be influenced in his inter-

V. ELEMENTARY ANALYSIS

pretation of each unit— W , T^2 , and V —by every other, as schematically outlined in the discussion of interpretational vibrations caused by broadening the context (see chapter 2, section 13). We have not, however, found it advisable to illustrate the complications of such vibrations. We have limited ourselves to symbolizing that the analyst operates with two interpretations W_1 and W_2 of W , and two interpretations V_1 and V_2 of V . Thus, the sequence WT^2V gives rise to eight interpretations:

$$\begin{array}{cccc} W_1U_1V_1 & W_1U_1V_2 & W_1U_2V_1 & W_1U_2V_2 \\ W_2U_1V_1 & W_2U_1V_2 & W_2U_2V_1 & W_2U_2V_2 \end{array}$$

At this stage we face the decisive and so far only roughly suggested problem, Does U^1 or U^2 fit in if it is placed in the context instead of T^2 ? Let us at once presuppose that we do not consider stylistical impossibilities to furnish disconfirmations of fitness. U^1 and U^2 may be long sentences or sentences in different languages from T^2 and therefore do not fit the text from the literary point of view. This does not imply anything as regards the fitness of the cognitive meaning of U^1 , that is, U^1 as expression of an assertion.

If U^1 is found to fit into the context W_1V_1 , this is taken as a *weak confirmation* of T^2 being synonymous with U^1 , that is, of occurrence No. 1 of T^2 being *subsumable* under the concept ‘occurrences of T^2 within M_1 (or M_2) that satisfy the definitoid D-formulation TUM interpreted in one plausible way, T_1 (or T_2) U_1V_1 ’. If U^2 also is found to fit into the context W_1V_1 , this is taken as a weak confirmation of subsumability under T_1 (or T_2) U_2V_1 . (There is no limit to the number of diverse interpretations U_1, U_2, U_3, \dots under which a given occurrence might be subsumable.)

If U^1 is found to fit into the context W_1V_1 , but not into the context W_2V_1 , the weak confirmation is followed by a weak disconfirmation. To answer the question of whether occurrence No. 1 of T^2 satisfies⁹ the definitoid formulation TUV_1 , we shall have to go through all eight interpretations listed above. Such an analysis may be expected to turn out rather complicated and hypothetical.

If one *presupposes* that a certain definiendum, T^2 , is used in the same sense every time it is used within a context, a strong confirmation (or a strong disconfirmation) in relation to one occurrence can automatically be taken as a strong confirmation (or disconfirmation) in relation to the total

context. There is, however, seldom any reason to believe that such a presupposition adequately describes usage within the context.

If the subsumption analysis belongs to the consistency-analysis subclass—authors being studied as regards their tendency to follow their own introduced terminology—one of the chief difficulties is the limited number of instances of the definienda. Sometimes the authors hardly use their defined terms. Furthermore, there is the difficulty that most occurrences give rise to only very weak confirmations or disconfirmations.

It is time to go into detail about what is to be understood by a meaning that fits the context, and what criteria of fitness can profitably be used in research. As an introduction to such a study we propose to give some illustrations of subsumption analysis.

V.15. Illustration 1: Irving Fisher on 'Wealth'

The first example that I shall give is rather trivial and simple. Its aim is to illustrate figure 3. Examples from philosophy would easily run into hundreds of pages. This does not imply that logical analysis carried out according to the principles of this book cannot be presented within reasonable space, but that the working material and inferences from it would demand very extensive space. This is analogous to linguistic research and many other scientific contributions: the published material is generally but a small fraction of the systematized material collected and analyzed.

Irving Fisher (1919: 3) says in his *Elementary Principles of Economics*, «Properly speaking man is wealth, just as, properly speaking, man is an animal. But we so seldom need in practice to take account of man as wealth that the ordinary meaning of wealth includes only *material objects owned by human beings* and external to the owner».

In a commentary on his statement, Fisher says, «The above definition of wealth --- agrees substantially with the usual understanding of businessmen».

That is, Fisher offers a definition as a description of usage among businessmen. The definiendum is expressed by «wealth» (and perhaps with synonyms, some of them in foreign languages). As analysts, we propose the following reformulation:

If x is an instance of the expression «wealth» within a context defin-

V. ELEMENTARY ANALYSIS

able as «professional talk or writing of a businessman», *x* may—without a change in connotation—be replaced by the expression «material objects owned by human beings and external to the owner».

It is to be noted that this version of the definition is adapted to the language habits of the analyst, or, in the last resort, to the readers of the analyst's papers. The reformulation is not adapted to businessmen without logical training.

What Fisher claims is somewhat reduced by the word «substantially». The definition is said to agree «substantially with the usual understanding of business men». Considering the frequency with which the word «wealth» is used (more than once a second?), we have an enormous amount of material at hand that is relevant to the hypothesis. It is, however, not easy to decide in any concrete case whether an instance of the expression «wealth» confirms or disconfirms the hypothesis.

In connection with his definition, Fisher says, «In this book we shall follow ordinary usage by employing this narrower meaning except occasionally when it will be found convenient to refer to the broader meaning» (Fisher 1919: 13). From this we conclude that his definitoid formulation also intends to express a definition as rule, and that the intended field of application includes his book, «except occasionally». Maybe Fisher also can be regarded as a businessman. Two things are here to be tested: first, the hypothesis on actual usage; and second, the question of whether Fisher follows his own rule.

After the introduction, the word «wealth» occurs four times on the next page. We shall confine our discussion to the first occurrence. He says, «It [wealth] is confined to this little planet of ours, ---». Substituting the definiens for «it», we get the formulation «Material objects owned by human beings and external to the owner are confined to this little planet of ours». May this instance be taken as confirmatory?

One of the most direct, most reliable methods of deciding the issue is to interview Fisher, convincing him that our purpose is so important that he should listen attentively and think deeply before answering. We then would simply ask him if he thinks he used «wealth» as a synonym for his definiens in this particular instance. A positive answer counts as confirmation; a negative, as disconfirmation.

This method of questionnaires and interviews is, however, generally not possible. The author may be dead, uninterested, not sufficiently honest,

or not sufficiently trained in analysis. We will, therefore, presuppose that our only direct material is the written text containing the immediate context of the instance of «wealth».

In the absence of other kinds of material, we have to rely on rather crude inferences: if the formulation in which definiens is substituted for definiendum seems malapropos in the wider context, or if it expresses a view that we do not believe the author would agree to, then it is warranted to conclude, «Nonsubsumable, an instance of disconfirmation». In the present case, one may tentatively assert that the first occurrence of «wealth» following the quoted definition of Fisher confirms the hypothesis that he follows his own definition.

V.16. **Illustration 2: Historians on «History»**

Our second illustration is worked out in some detail to stress the various more or less difficult questions involved in subsumption analysis and in preliminaries that have to be discussed before going into subsumption analysis proper.

The Social Science Research Council, Bulletin 54, entitled *Theory and Practice in Historical Study: A Report of the Committee on Historiography*, contains a chapter called «Propositions». Concerning these «propositions» we read, «The committee assumed that every branch of knowledge presents or rests upon a number of propositions accepted by persons competent in such fields as valid in themselves and for application» (SSRC *Bulletin* 1946: viii). The chapter «Propositions» is a tentative list of such propositions. I strongly recommend that readers consult the SSRC bulletin from which this illustration is taken, not only because doing so will enable them critically to evaluate my analysis, but also because the efforts of clarification carried out by the Committee on Historiography are instructive.

Professor Gottschalck defines some of the basic terms used in the propositions. This is done in an introduction (*ibid.*, p. 133), the first part of which reads:

«In order to promote clarity and understanding, the committee has deemed it wise to define the meaning it has attached to certain basic terms frequently used in the Propositions.

The word *history* is used in at least five overlapping senses: (1) the systematic study of, or a treatise dealing with, natural phenomena—as in «natural

V. ELEMENTARY ANALYSIS

history» or «life history»; (2) the past of mankind (or any part thereof)—as in «history as actuality» or «the totality of history»; (3) the survivals and records (whether primary or secondary) of the past of mankind (or any part thereof)—as in «history as actuality» or «the totality of history»; (3) the past of mankind (or any part thereof)—as in «recorded history», a «history book», or a «case history»; (4) the study, representation, and explanation of the past of mankind (or any part thereof) from the survivals and records—as in «written or spoken history»; and (5) the branch of knowledge that records, studies, represents, and explains the past of mankind (or any parts thereof)—as in «department of history» or «school of history».

The sentence «The word *history* is used in at least five overlapping senses:» may be interpreted in different ways. To eliminate some ambiguities of importance in the present connection and to adapt it closely to the terminology of this work, we shall use the following somewhat pedantically formulated precization. The precization is fairly strong, but scarcely the most plausible. More plausible precizations are discussed on page 283.

«The occurrences of the word «history» within the context of the section «Propositions» (not including the four footnotes) on pages 134–140 of the source are instances of «history» being used as designation for at least five different concepts (connotations, propositional significations), each occurrence being a designation of one of these concepts or possibly of other concepts. Each of the concepts may be expressed by conjunctions (and connections) of formulations of conceptual characteristics in such a way that some formulations occur in more than one conceptual characteristic expression (designation).»

The first part of the above quotation will be called «the five-sense theorem». It may plausibly be interpreted as follows:

Each instance of the word «history» within the context «Propositions» (not including the four footnotes) on pages 134–140 of the source is for the eight persons of the Committee on Historiography synonymous with one of the following five numbered expressions or classes of expressions, or with expressions heteronymous with all of them. There is at least one instance of synonymy for every one of the numbered expressions or classes of expressions.¹⁰ (The numbered expressions are reproduced on page 280.)

Interpreted in this way, the five-sense theorem can be tested by sub-

sumption analysis. Each of the questions characteristic of subsumption analysis and mentioned in sect. 13 is relevant to the test. The first question, about intended field of application, appears an easy one at first glance. The field is the aggregate of sentences composing the twenty-one propositions. One of the doubtful instances is the occurrence in the *headings* of propositions 19–21. Do the headings belong to the propositions? We shall include them in the context surveyed, even if this conclusion does not follow from the most plausible interpretation of the designation of field of intended application. Further, the instances of the complex expressions «written-history» and «history-as-actuality» are somewhat doubtful. Does the «-»-sign indicate that the expression as a whole should have word status? In the formulation of the five-sense theorem given by the committee, the expression «history as actuality» (without a «-»-sign) is quoted as an instance of the second concept. But there is in the propositions no instance of that expression. This suggests that the expression «history-as-actuality» should be interpreted as «history as actuality», and therefore as three words. This, in turn, indicates that «written-history» should be interpreted as two words, the «-»-sign having a different function from that of indicating word status. The discussion in this paragraph about the intended field of application presupposes the auxiliary hypothesis «The word «history»» is interpreted to mean the same as «the word «history», if having word status», and not as «the letter-sequence «history»».

Before we continue to illustrate subsumption analysis, we wish to point out that we have not the slightest reason to insist that publications of subsumption analyses normally should go into such details as are exposed in this section. However, if elementary analysis is to be a part of the accepted techniques of research, and if the affirmations presupposing such analysis are ever to achieve the status of testable, well-confirmed hypotheses, then the research worker must go into all details appreciably affecting the scope and validity of the hypotheses. The pedantic exposition of details of procedure are carried out here only because few hypotheses presupposing elementary analysis seem to be based on painstaking research. When new habits of research are developed, extreme condensation of exposition, such as is found in the highly developed parts of the life sciences, will not only be possible without loss of interpersonal preciseness, but will itself be part of the requirements of research.

V. ELEMENTARY ANALYSIS

Let us proceed to formulate the five-sense theorem. It may be plausibly interpreted as a sort of synonymy hypothesis, an effort toward a complex descriptive definition. The definiendum expression is «history»; the field of intended application is the text («Propositions») referred to. As regards the definiens expressions, they may be formulated as follows:

1. «the systematic study of, or a treatise dealing with, natural phenomena»,
2. «the past of mankind (or any part thereof)»,
3. «the survivals and records (whether primary or secondary) of the past of mankind (or any part thereof)»,
4. «the study, representation, and explanation of the past of mankind (or any part thereof) from the survivals and records»,
5. «the branch of knowledge that records, studies, represents, and explains the past of mankind (or any parts thereof)».

The five-sense theorem is a descriptive definition if the expression «as in» (see the original quotation, pages 277–78) can be interpreted so that it may be taken to be synonymous with «as in and only in». If—which is more plausible—it is stated only that the occurrences, for example, of «life history» and «natural history» include *instances of* «history» being used synonymously with definiens expression 1, then there is not the slightest indication of the limits of that subclass of occurrences that make up the intended field of application of the synonymy hypotheses concerning «history» and definiens expression 1. That is, we get a sort of dictionary technique of indicating senses, which, as stipulated in chapter 4, pages 192–93, cannot be viewed as giving descriptive definitions. We have in that case a total field of application for five different synonymy hypotheses, but no delimitation of the fields intended to be covered by each of the hypotheses. This does not make any difference to our illustration of subsumption analysis, however.

The five-sense theorem might also be plausibly interpreted as a description of normative definitions made by the committee members and covering the propositions within their intended field of application. We shall, however, use the interpretation making the theorem a *descriptive* hypothesis of usage, but not a descriptive definition or normative definition.¹¹

Let us then, after these preliminaries, take up the subsumption analysis itself. The first instance occurs within proposition II, which reads:

«The utmost understanding of history attainable to the human mind is to be acquired by extending historical research and thought as far as possible in the direction of comprehensiveness and synthesis as well as by inquiring more deeply into the particular and the unique».

Substituting definiens expressions 2 and 3 for «history», we obtain the following formulations:

- (1.1) «The utmost understanding of the past of mankind (or any part thereof) attainable ---».
- (1.2) «The utmost understanding of the survivals and records (whether primary or secondary) of the past of mankind ---».

In relation to these sentences and three others obtained by using the remaining three definiens expressions, we shall have to pose the question, «Is occurrence number 1 subsumable under the concept ‘occurrence in conformity with the synonymity hypothesis x’?»—where x is a number corresponding to a definiens expression number.

Now, what we have to answer primarily is not whether or not the committee assumed (believed) the occurrence to be in conformity with hypothesis x. We have, as analysts, to take the standpoint of subsumability. On the other hand, we shall primarily have to investigate subsumability based on hypotheses about how the committee interprets the definiens expressions and the sentence within which each occurrence is found. Thus, we shall have to try to find out what the committee meant by proposition II.

Now, I think it is rather certain that (1.1) and (1.2) do not contain contradictions in any plausible logical or empirical sense. If they had, we should have said that occurrence number 1 is not in conformity with synonymity hypotheses 2 and 3, stating that there is intrapersonal synonymity for the committee between the sentence headed «Proposition II» and the sentences (1.1) and (1.2) obtained by substituting definiens expressions 2 and 3 for «history».

A criterion of disconfirmation that is not necessary, but is sufficient, may be stated as follows: substitution of definiendum with definiens in the occurrence sentence results in a sentence containing logical or empirical contradictions from the point of view supposed to be that of the authors,

V. ELEMENTARY ANALYSIS

and there is in the immediate or remote context no indication that the sentence was intended by the authors to express contradictions.

As regards the question of whether the authors of the sentence assumed the occurrence to be in conformity with synonymity hypotheses 2 and 3, a third clause may be added to furnish a criterion of disconformity: there is nothing in the immediate or remote context that makes it plausible that the authors should not have been able to see the contradiction and avoid it.

Absence of logical and empirical contradictions excludes strong disconfirmation of the synonymity hypotheses, but it does not necessarily bring any confirmation. Absence of disconfirmation may be an effect of extreme vagueness and ambiguity, which make it practically impossible to find out anything as regards contradictions.

There is, so far as I can see, nothing in the total text called «bulletin 54» that can give any appreciable confirmation of the synonymity hypotheses.

This property of occurrences—that they do not afford appreciable evidence in support of synonymity relations—is very common.¹² Thus we shall limit ourselves to concluding that «Occurrence number 1 is subsumable under the concept ‘occurrence in conformity with the synonymity hypotheses 2 and 3’». As regards those hypotheses themselves, we can only conclude that occurrence number 1 did not bring disconfirmation, but a *very weak* confirmation (the substitutions give good meaning).

I imagine that the committee intended to use the word «history» in the first rather than in the second sense, but that is only a hypothesis of a rather speculative kind based on some acquaintance with historiography.

Let us now proceed to definiens expressions 1, 4, and 5. The substitution of these expressions for the definiendum does not seem to result in a proposition involving logical or empirical contradictions. The above-mentioned criterion of disconfirmation gives as a conclusion «Not strongly disconfirmed», but other criteria should also be used. Taking the rest of the chapter as a context, I think we may assume that a proposition about «natural phenomena» does not fit in. There would be a breach in continuity that is seldom found in the writings of presumably sane persons. Thus, a synonymity hypothesis corresponding to definiens expression 1 is ruled out by a disconfirmation that I think may be classed as strong, even if the relevant arguments and observational evidence are in practice difficult to obtain. The same may be said in relation to expression

4 and even to expression 5, except that the degree of disconfirmation is here less strong.

Although the point is not relevant to our present analysis, I should like to mention that the continuity hypothesis used as an *auxiliary hypothesis* in disconfirming some synonymy hypotheses can also be applied to the question of whether a mistake appears in the introduction quoted on pages 277–78. It is there stated, «The word *history* is used in at least five overlapping senses: (1) the systematic study of, or a treatise dealing with, natural phenomena ---». Is «history» used in this sense in the propositions, or would it be a mistake, a disconfirmable hypothesis, to state that it is?

So far as I can judge, the assumption of synonymy between «history» and definiens expression 1 goes strongly against the assumption of thematic continuity, and this holds in relation to every single occurrence of «history». The hypothesis seems to be disconfirmable. Nothing is said about natural phenomena, in general, in the propositions. Maybe I misinterpret the definiens expression «natural phenomena». My interpretation of the definiens expressions is an auxiliary hypothesis acting as a premise in all the subsumption hypotheses.

We accept the conclusion «disconfirmed» in relation to the synonymy hypothesis according to which «history» as used in the propositions is at least once used synonymously with definiens expression 1, «the systematic study of, or a treatise dealing with, natural phenomena». This definiens expression and the propositions are here interpreted as we, as analysts, believe the committee would interpret them.

The disconfirmation is a disconfirmation also of the five-sense theorem as precized on pages 277–78. However, as indicated briefly on that page, the interpretation is not the most plausible one. My respect for the historians writing the SSRC bulletin makes me take the disconfirmation as a symptom of the precization's not being the most plausible one. Let us, therefore, take up for consideration five-sense theorems derived by other precizations of the introductory note quoted.

The first sentence of the introduction (see page 277) suggests that the committee has attached some definite meanings to terms (a) occurring in the propositions and (b) used in the propositions. It seems natural for a committee to «attach meanings» (in many plausible senses of that expression) to words as they are used by the committee *in the writings of the committee*. Thus, I think it is plausible to interpret the first sentence of the introduction in

V. ELEMENTARY ANALYSIS

such a way that «the Propositions» can be viewed as a designation of the field of intended application of the following synonymity hypotheses—not only as an indication of where the definienda are to be found.

The next sentence, «The word *history* is used in at least five overlapping senses ---», gets a fairly well delimited meaning as regards field of intended application if «is used» is taken to mean the same as «is used in the propositions». As we have already pointed out, however, the definiens expressions and the propositions taken as context suggest that the intended field of application must have been a broader one. What, then, is the field intended? Textbooks of history? Writings of historians? Writings of those historians who are members of the committee?

We are here concerned with a difficulty that nearly always turns up in connection with subsumption analyses involved in testing whether authors follow their own definitions: what is the intended field within which the definitions are to be tested?

For all heteronymous hypotheses about which field is the field of intended application, there is a corresponding five-sense theorem. On account of the great number of nearly equally plausible interpretations, we shall abstain from explicit formulation of any of them.¹³

So far, we have analyzed only one occurrence of «history», namely, the one in proposition II. Let us proceed to take into account occurrence number 3 found in proposition V:

«In a scientific methodology, clear distinctions must be maintained between the unrecoverable totality of the past, the records of the past, and written or spoken history».

Inserting each definiens expression into the sentence instead of «history», I think no logical contradictions arise, perhaps not even clear-cut empirical contradictions. Nonetheless, the text is made rather incoherent, malapropos, stupid, and discontinuous if definiens expression 3 is inserted. The same holds for some of the other insertions. How this argument about incoherence, stupidity, and so on, is to be made precise and validated, I do not know.¹⁴ The attitude I should tend to adopt is to let the impression of incoherence or stupidity count as a rather strong disconfirmation of the synonymity hypothesis involved, at least until somebody challenged it. If that happened, I would find it fruitful to try to make it precise and go into detailed argumentation.

Definiens expression 4 seems to fit the context best. It expresses, probably, the sense given to «history» by the committee, if the sense is one of the five mentioned. This conclusion conforms with indications in sense number 4, as described in the introduction (see pages 277–78).

In concluding this discussion, I should like to stress the uncertain, vague, and elusive character of the arguments that one has to rely on in subsumption analysis. This character makes it of great methodological importance to omit assertions that presuppose subsumption analysis from argumentations in which those assertions do not play an important role for the validation of the conclusions. Further, that character makes it advisable not to invite disputes about assertions involving subsumption analysis. One may expect the dispute to develop in such a direction that only rather difficult and tedious empirical investigations, which none of the disputants are willing to carry out, can settle the issue.

As material for our illustration in this section, we chose a text written by authors who probably did not have the aim of working out exact hypotheses of usage, but only of *reminding their readers* of some persistent ambiguities in basic terms.¹⁵ Our analysis does not imply any criticism. The quoted introduction seems to us admirably apt to warn readers of ambiguities. It is to be hoped that it also will stimulate research on terminological issues as a part of historical foundation research (*Grundlagenforschung*).

V.17. Survey of Difficulties of Testing Descriptive Definitions by Means of Subsumption Analysis

The practical and theoretical testability of hypotheses involved in descriptive definitions is largely uninvestigated. Testing normative definitions for whether or not the rules laid down are followed meets with the same difficulties. When we form a hypothesis that the rules are followed, the test of being followed is identical with a test of a descriptive definition. In the following we shall therefore limit ourselves to discussing descriptive definitions and synonymity hypotheses in general.

There are important properties of normative definitions other than that of being followed or not followed. We may ask: Is the normative definition fruitful (convenient)? The criteria and concrete testing of answers do not belong to elementary analysis as here conceived, however.

V. ELEMENTARY ANALYSIS

Difficulties of testing descriptive definitions are caused, among other things, by the following shortcomings: insufficient preciseness, specification, and elaborateness of

1. indications of definiendum,
2. indications of definiens, and
3. indications of intended field of application.

Even if we suppose that we have methods of raising the level of preciseness, specification, and elaborateness as much as we wish, there are still difficulties to overcome owing to

4. lack of knowledge about the denotation of the definiens (for example, objects denoted by the definiens), and
5. lack of knowledge about objects denoted by the statement of the intended field of application.

We may, of course, classify difficulties in other ways. As indicated in the preceding section, we have to assume that we know the beliefs of the author of a text. In the case of Fisher, we shall have to assume that we know the beliefs of businessmen. Difficulties arise from ignorance about the authors and from an inability to handle the many auxiliary hypotheses that must be evaluated before we can conclude, «Confirmative instance!» or «Disconfirmative instance!».

V.18. Definiendum Indications: Their Lack of Preciseness and Elaborateness

As mentioned previously, there is seldom only one expression functioning as the definiendum expression. Usually, it is tacitly understood that ordinary dictionary equivalents in foreign languages are to be included in a class of expressions functioning as definiendum. Sometimes, broader and less specified classes are included.

Seidel's list of eighty-three «*Satzdefinitionen*» (see page 215) is not limited to quotations in which the expression «*Satz*» occurs as the definiendum expression. Such a limitation would be rather arbitrary in relation to

the purposes of his list. Among the definiendum expressions, we find «Satz», «Sätze», «oratio», «sentence», «propositio», «enunciatio», «Grundform des elementaren Satzes», «Rede», «frase», «phrase», and «logischer Satz».

There are hundreds of so-called «definitions of truth», and their definiendum is hardly ever «truth». Occasionally, it seems as if the definiendum is not conceived or defined as an expression or class of expressions, but as a «notion» or «idea», or even a class of inorganic bodies. In such cases it must be asked, How is the definiendum expressed? The answer is, By means of words *such as* «true», «truth», and so on. These expressions are—in accordance with our terminology—the class of definiendum expressions. If no definite expressions are presented, there can be no normative or descriptive definition. A descriptive definition is an attempt by means of the definiens expression to indicate as exactly and precisely as necessary, for given purposes, what is expressed by the definiendum expressions. The definitions as descriptions describe the use of these expressions (for example, describe what sense they have, what they express). The material is usage in the form of *instances of use*, not primarily rules of use or definitions. The elementary analysis cannot presuppose that such rules and definitions are known.

When some philosophers state that they intend «to define truth», this does not give us any precise indication of what is conceived as definiendum. Not only «true» and «truth», but possible synonyms in foreign languages are thought relevant. Moreover, expressions such as «false» and «incorrect» are to some extent brought into the discussion.

Further, and this is very important, it seems as if a statement such as «Caesar died in the year 44 B.C.» is somehow thought relevant. This is perhaps because it is taken for granted that the author writing this sentence could just as well have written «*It is true* that Caesar died in the year 44 B.C.». In general, statements in textbooks are thought relevant. This is, however, a sort of anticipation from the point of view of analysis. It is one of the points to be reached as a possible conclusion, that «true» is used in such a manner that any assertion claims something that may be expressed by the word «truth».

It seems probable that *if* Bradley (see page 264) had specified which expressions he intended to speak about (for example, if he had specified his definiendum expressions), it would appear that he was talking about different things. His definienda would not be the same class of expressions. The

V. ELEMENTARY ANALYSIS

same, I suppose, would be probable in many other cases. As long as there is no agreement about what the disputants choose as the definiendum, there will be no discussion, but just declamation about things that might happen to coincide, but also might not.

I have herewith the pleasure of inviting the reader to find possible definienda on the basis of the following utterances of truth specialists:

«*Denn Wahrheit ist nichts anderes als ---*» (B. Erdmann).

«*Wahrheit eines Urteils besteht darin, das ---*» (ibid.). Meant as a synthetic theory, not a descriptive definition?

«*Die behaupteten Urteile, deren wir uns als gültige bewusst sind, nennen wir wahre im allgemeinsten Sinne des Wortes*» (ibid.). Note the indication of intended field of validity.

«*The truth of the sign consists of its adequateness ---*» (Fleming).

Real truth is, therefore, the correspondence of ---» (Hamilton).

«Hence *the definition of truth* which modern philosophy proposes: the agreement of ---» (Hodgson).

Truth means nothing but this, that ---» (Dewey).

«Ich glaube, *das Wort Wahrheit* in seinem gewöhnlichsten und natürlichsten Sinne *bezeichnet* ---» (Shute). Note the indication of range of application.

Perhaps many people are sure that these philosophers speak about the same thing. But I venture to predict that if the philosophers were invited to pick out from a given text instances that confirmed their theses, they would not agree as to which expressions were relevant. As long as there is no explicit delimitation of the class of expressions intended to constitute the definiendum, no hypothesis with scientific pretensions can be formulated. The extensive disagreements among philosophers make such explicitness highly desirable.

In other discussions, ambiguities as regards the indication of the definiendum are still more palpable. In the literature of symbolic logic, there is much talk about implication, and many attempts at definitions with descriptive pretensions. In such cases, what is the definiendum? If the expression «if --- then» in scientific literature is taken as such an expression, many definitions, for example, those derived by means of a matrix, meet

with grave difficulties. If «if --- then» or «implies» in scientific literature is not taken as definiendum expression, what is then taken as definiendum?

It seems improbable that discussions on «the meaning and symbolization of implication» can be fruitful without a more precise indication of what the discussion aims at. One of the things to be done here is to clarify whether one wishes to give the definitions of «implication» any descriptive function, and if such a function is aimed at, to choose a class of expressions acting as definiendum.

V.19. Definiens Indications: Their Lack of Preciseness and Elaborateness

If the definiens expression in a descriptive definition is not described fairly precisely or if it is not a fairly precise expression, then nothing definite has been asserted and nothing definite can be tested. If we succeed in delimiting the ten most plausible interpretations $U_1 \dots U_{10}$, our conclusions may run as follows: «if by U is meant U_1 , the synonymity hypothesis expressed or implied may be viewed as strongly confirmed; if U_2 is meant, it may be viewed as neither confirmed nor disconfirmed, ---; if U_{10} is meant ---».

Suppose we single out 100 controversial statements all of which can be given the form « T 's have the property ---» (for example, «Democracies are ---»). If, now, a definiens formulation of T permits as plausible directions of precization $U_1, U_2, \dots U_{10}$, the ambiguity of the definiens might be tolerated if the 1,000 statements created by using $U_1 \dots U_{10}$ instead of T in the 100 controversial statements would not result in a new distribution of acceptances and rejections among the disputants.

The importance of the difference between harmless and harmful ambiguities of definiens is aptly suggested by Schumpeter (1942: 243):

Equating «making decisions» to «ruling», we might then define democracy as Rule by the People. Why is that not sufficiently precise? It is because it covers as many meanings as there are combinations between all the possible definitions of the concept «people» (demos, the Roman *populus*) and all the possible definitions of the concept «to rule» (*kratein*), and because these definitions are not independent of the argument about democracy.

Instead of a single definiens expression, there are usually several. For each, there is a separate field of application tacitly assumed or explicitly

V. ELEMENTARY ANALYSIS

mentioned. In such a case the question arises of whether the various definiens formulations form a list of heteronymous expressions. If they are not fairly precise, we cannot treat them as expressions of different «senses» of the definiendum.

These weaknesses would make subsumption analysis impossible, because nothing definite is provided under which to subsume. We can only resort to systems of if-statements. When there are many definiens expressions, however, the construction of such systems is apt to require too much work relative to our need to test the synonymy hypothesis. We are thus led to give up the test or to make an unsatisfactory, incomplete one. It would seem to be in the interest of the future development of elementary analysis as a science to give up the test, in such cases, and reject the synonymy hypothesis as unworkable, that is, as being too ambiguous for use.

Consider the following situation. At a conference on standardization of terminology within political science, it is proposed that the scientists stick to the «correct» use of the word «democracy». To clarify what concept of «correctness» is implied, the conference decides to stick to the definition of the expert in linguistics, Otto Jespersen (1922). He says, «Our conceptual delimitation (*Begriffsbestimmung*, *begrepsbestemmelse*) of the correct as applied to language (*det spårkriktige*) is ---, that it is the socially accepted (*samfunnsmessige*), that which is required by the language community. What is opposed to that is incorrect from the point of view of language. And if this delimitation is maintained consistently (*skarpt*), then really all is said that needs to be said».

Now, let us suppose that some of the rival interpretations of «democracy» are put forth by their advocates. How can we attempt to subsume the usages under the definiens of 'correct as applied to language'? What is meant by «required by the language community»? Is the requirement of a language community different from the requirements of its members? If so, how am I to find out the community requirement? Are the requirements somehow detected inside usages, or have they the form of logical constructs?

So little is indicated by the quoted definiens expression that there is scant reason to bother with lists of precizations, and without such lists, subsumptions would be highly arbitrary.

The list of formulations on truth on page 288 exemplifies a low level of preciseness as regards definiens. In the discussion about the so-called «defi-

nition of truth», the expression «truth» is extensively commented on. Several directions of precization are found to be plausible. In spite of this, there are still published statements on truth with crude definiens formulations obscuring the discriminations already adopted by others. In such cases, the statements seem to us to be devoid of research value. The following examples do not belong to the statements with the most indisputable ambiguities.¹⁶

1. «Ein Urteil darf «wahr» genannt werden, «wenn feststeht, dass es sich immer und unter allen Umständen verifizieren wird»» (Moritz Schlick).

From the context, it may perhaps be inferred that Schlick here refers to sentences that *by definition* are given the «truth value» «true». Thus, for example, «It is Monday today or it is not». Basic ambiguities of philosophical importance are associated with the words «*darf*», «*feststeht*», «*Umständen*» and «*verifizieren*». Possibilities of subsumption on the basis of well-established auxiliary hypotheses are scant. The term «*darf*» makes it difficult to determine whether an N- or a Ds-definition, or a combination, is intended.

2. «Ein Urteil ist wahr, wenn es einen bestimmten Tatbestand eindeutig bezeichnet» (Moritz Schlick).

In the definiens formulation of this definitoid statement, the expressions «*Tatbestand*» and «*eindeutig bezeichnet*» are especially difficult to interpret so as to make subsumption possible. There are a great number of directions of precizations, some of which have been adopted by Schlick's critics, and others by his sympathizers.

3. «Das Kriterium für die Wahrheit oder Falschheit des Satzes liegt dann darin, dass unter bestimmten (in den Definitionen angegebenen) Bedingungen gewisse Gegebenheiten vorliegen oder nicht vorliegen» (Moritz Schlick).

In this sentence the expressions «*Bedingungen*», «*Gegebenheiten*», and «*vorliegen*» make it difficult to carry out subsumption.

4. «When we say: something is true, we mean that «it agrees with observed facts» (Bertrand Russell).

The ambiguities of «agree with», «observed», and «fact» have been extensively discussed. Such a formula has no research value un-

less we precize it in one of the directions already indicated in past and contemporary discussions among philosophers and scientists. For purposes of popularization it *may* have some value. Even that seems implausible, however, because even among persons who have never read a philosophical text (except perhaps some parts of the Bible) there is some tendency to ask for precizations. I think the tendency—which is not prevalent among them—should be encouraged by offering them fairly precise formulations.

5. «A form of words is true if a person who knows the language is led to that form of words when he finds himself in an environment that contains features that are the meaning of those words, and these features produce reactions in him sufficiently strong for him to use words that mean them» (Bertrand Russell).

The extensive discussions going on among professional philosophers indicate that the discussions are not thought of as discussions about alternative formulations of one and the same proposition (statement), but about different statements on one and the same issue. They are conceived as rival «theories», perhaps rival theories about usage and about characteristics deducible from usage. On this point there are, however, divergent views and considerable lack of preciseness.

To test the so-called «truth theories» conceived as descriptive definitions, we prepared a list of about 8,000 occurrences of «true», «truth», «truly», «*vrai*», «*vérité*», etc., in scientific literature. The next step was to inspect the definitoid formulations on «true», «truth», etc., in the light of these instances. Let us consider an example picked out at random:

L. V. Pirsson says in his *Textbook of Geology* (1924), «The actual rate at which geological work is accomplished, from the human standpoint, is, in general, very slow. Of course, in some cases, as where in a volcanic eruption, a very large amount of matter is suddenly transferred from the inside to the outside of the earth, the work done is not only evident, but startling. The same would be true for instance in the case of heavy landslides. But, in general, the amount of work done at this rate is small, compared with that accomplished, much of it imperceptibly, most of it so slowly, that it is only in viewing the results achieved that we can *truly* judge of its extent». . . . «The erosive power of a current varies as the square of the velocity, with

equal size and distribution of particles. That this is true may be easily proved.»

The juxtaposition of instances such as these of the use of «true» with definitoid formulations reveals so many difficulties of subsumption that we may wonder how philosophers can have taken seriously the discussion about so-called «theories of truth».

V.20. Indications of Field of Application: Lack of Preciseness and Elaborateness

Dictionary meanings are usually presented with rough indications of intended field of application for each meaning. Some definiens expressions are listed as meanings. What is asserted about them might perhaps be expressed thus: «every single instance of T (definiendum) is synonymous with one and only one of the members of the following heteronymous list of expressions: U_1, U_2, \dots, U_n ». Thus, the lexicographer perhaps intends to assert that the definiens expressions taken together have a total field of application that is vaguely limited, but he does not intend to trace out the field for each definiens expression U_i . This means that one cannot use the list to interpret any found instance of T. The only thing we may infer about the instance is that it is synonymous with one of the members of the definiens list.

Usually the lexicographer probably intends to make less pretentious assertions, for example, that in certain representative classes of texts, most of the meanings of the expression T are indicated roughly by the definiens expressions $U_1 \dots U_n$. Sometimes it is explicitly stated that the total field is not equal to the total class of occurrences of the definiendum. Thus, in the *Dictionary of Philosophy and Psychology* (Baldwin 1960) we read, «In political and ethico-political reasoning, different meanings of freedom may be distinguished: (a) a nation is said to be free when not under the rule of another nation, or when not subject to a tyrant who is above law. (b) ---».

In the article on «vague» in the *New English Dictionary* (Murray 1884–1928), one reads, «1. *Of statements, etc.*; Couched in general or definite terms; not definitely or precisely expressed: deficient in details or particulars. 2. ---. 9. ---». Looking through the nine dictionary meanings listed, we find that «statements» are not mentioned except under item 1. From this

V. ELEMENTARY ANALYSIS

we may infer that the three synonymity hypotheses under item 1 have a *total* intended field of application covering all cases in which «vague» is used as a predicate of «statements». The «etc.» may indicate that the hypotheses cover a somewhat larger, not specified field.

The absence even of implicit indications of intended field of application for each definiens in ordinary dictionaries makes most entries fall outside the domain of normative and descriptive definitions, but not outside the scope of hypotheses about synonymic alternatives. Entries in technical dictionaries and statements found in scientific and philosophical literature fairly often contain traces of indications. We shall mention some examples.

Bryce's definitoid Statement No. 7 (quoted on page 250) implies that «in its old and strict sense» «democracy» denotes («connotes» in our terminology?) «a government in which the will of the majority of qualified citizens rules, ---». We may interpret Bryce's formulation to imply the following: «Sometimes «democracy» is used synonymously with «a government in which the will of the majority of qualified citizens rules, ---». The class of instances covered by this definiens expression is the class of old instances that also is the class of strict instances.» Thus interpreted, the expression «old instances» indicates the field of intended application. This is a somewhat imprecise and vague expression! The expression «strict» seems to be even less apt to function as an indication of field of application because no criteria of strictness are given. Given an instance, how am I to decide whether the instance is within the field of application delimited as the field of strict application? «T means U within the field of strict use, and the use of T is strict when T means U.» Such tautologies do not help us in subsumption analysis.

Here are some definitoid formulations that can be so interpreted that they give rudimentary or tautological information about the intended field of application:

1. «*Right*. (1.) --- *Philosophically or ethically* the term is often used to apply to benefits or privileges that the individual or group feels that it ought to receive from society or from the world at large ---» (Fairchild 1957).

«Philosophically» may mean «as used within philosophical discussions» or it may mean «when used in philosophical senses»

(or it may, of course, mean something else). In the first case, a somewhat more helpful suggestion for subsumption analysis is made than in the second case.

2. «*When we speak of the democracies we mean those countries where the governments ---*» (Blaich and Baumgartner 1966).
«We» may refer to the two authors, T. P. Blaich and I. C. Baumgartner, and the «speaking» may refer to the book from which the quotation is taken—but presumably a larger field is intended.
3. «*In a wide sense, democracy means a kind of society or way of life, one of the main characteristics of which is equality: ---*» (Wade 1946).

The information intended to be conveyed is, perhaps, only the information, first, that there *exist* occurrences of the term «democracy» such that it means the same as «a kind of society ---», and second, that if different concepts of democracy are classified in terms of richness in connotation, the one mentioned belongs to the rather poor ones. Nothing is thereby said about how to recognize the occurrences that are examples of the wide sense mentioned.

It is, of course, not contested that information about the existence of certain usages often helps us to understand a text, but such statements about usage should not be identified with descriptive definitions. In descriptive definitions the subject matter must be somehow delimited independently of the definiens indication. If it is not, the statement may be formulated thus: «occurrences of class G of the term «a» are such that «a» is synonymous with «b»». The first part of the formulation introduces a reference to a field of application, but it is, in the last part of the sentence identified with the field in which definiendum is synonymous with definiens—an instance of *circulus in definiendo*.

About «equivocate», the *Oxford Dictionary* includes, among other things, «4. In bad sense: to mean one thing and express another, to prevaricate». The subsumption analyst will here have to go into complicated problems of ethics. In the article on «vague» in the *New English Dictionary*, one reads, «2. *Of words, language, etc.* not precise or exact in meaning». At first glance, the field indication of this definitoid formulation may seem fairly precise, but as quoted on pages 293–94, the field of application related to sense number 1 is «Of statements, etc.»; and that of sense number 3 is «Of

V. ELEMENTARY ANALYSIS

ideas, knowledge, etc.». How are we to distinguish these fields? It seems natural to elaborate the «etc.»'s of the three field indications in such a way that they overlap. If there are no field indications specific to each sense listed, each hypothesis of synonymy becomes indefinite as regards its scope.

More precise is the following field indication: «democracy—in *political science*, that form of government in which the people rules itself, ---». The indications of intended field of application in the statements of Bryce listed on pages 249–50 are all more or less difficult to use in concrete cases. Some of them seem to imply that the field is the total class of instances of «democracy», but such pretensions seem preposterous and are not in harmony with my high opinion of James Bryce. This makes me reject synonymy hypotheses implying such fields. If that interpretation of Bryce is rejected, however, we are left with such a multiplicity of approximately equally plausible interpretations that it is hard to make a choice.

The importance of fairly precise indications of intended field of application does not need to be argued in detail. Lack of preciseness and elaborateness makes it necessary to add to subsumption hypotheses «*if* the occurrence is one covered by the synonymy hypothesis». The confirmatory or disconfirmatory weight cannot be judged as long as we cannot decide in most cases whether an occurrence of an expression belongs to the class of occurrences intended to be covered by the definition.

V.21. A Vicious Circle Created by Interpreting Definiens on the Basis of Examples Offered in Support of Normative and Descriptive Definitions

Subsumption analysis soon reveals that presumably intelligent and competent subjects are astonishingly uncritical when they read texts containing definitoid statements and applications of those statements. The uncriticalness seems so great that it is necessary to try to find special reasons for it. Herman Tønnessen (1948) worked out questionnaires that included small texts in which definitions were used. Some of the texts were worded as follows: «The word «typical» seems to be used in different ways. Occasionally it is used in the sense of «frequent», as, for example, in the sentences: ---.---». He inserted sentences that made it preposterous to believe that the word was used as indicated in the text. Nevertheless, there was a tendency

among the subjects to agree to the subsumability. Some questionnaires were constructed with questions such as «Do you think «a» is a good or bad example of «b» being used in the sense of «c»?» They revealed lack of definite criteria of subsumability.

According to Tønnessen, one of the main reasons subjects' uncritical attitude toward definiens formulations, and the subsumption of occurrences under the definiens concept, is their tendency to interpret the definiens formulation in the light of subsequent occurrences of the definiendum expression. Thus if «type» is defined, and the author uses the sentence «a is a type», the subjects change their interpretation of the definiens formulation if the properties they attribute to a seem not to allow subsumption if they stick to their initial interpretation. They dare not rely on their initial interpretation of the definiens. This procedure radically destroys the function of the definition: instead of giving us precise hypotheses and norms for usage to be tested by observing usage, the definitional formulation is looked on as a formulation the meaning of which is to be understood by means of the use of the definiendum within the field of application. As a result, there is a tendency to accept uncritically whatever subsumptions are explicitly or implicitly asserted.

The uncriticalness toward definitions is partly fostered by a bad tradition within elementary analysis. To quote Tønnessen (1948: 42; my translation):

It is current analytical and lexicographical practice to slur over the difficulties of subsumption by avoiding explicitly mentioning whether exemplifications are meant to be didactically useful illustrations of a definite theory of usage or whether they are meant to furnish material for a decisive verification of the theory. This brings the proponents of the theory into a favorable position from the point of view of tactics in controversies. The favorable position enhances the self-deception concerning the unassailability of the theory—without improving appreciably its tenability in practice. «To bring out more precisely what I mean, I shall give an example ---» is a stereotype cliché. Under such circumstances, the readers tend to perform the subsumption easily because the choice of example influences the interpretation of the described usage [the definitoid formulation] in such a way that it nearly by definition implies the subsumability of the example. This is then taken to support the tenability of the theory [the Ds-definition] as a symptom that the theory covers the field of application represented by the «example».

V.22. A Vicious Circle Created by Interpreting Occurrences (Instances) Offered in Support of a Synonymity Hypothesis on the Basis of That Hypothesis

The uncritical attitude toward definitoid formulations suggestive of descriptive definitions seems also to owe in part to a tendency within lexicography to describe instances (occurrences) halfway as didactical illustrations and halfway as confirmatory instances. Because of the vague, incomplete, and imprecise way in which the instances are offered, readers use their interpretation of the definitoid formulation as a basis for their interpretation of the instances (occurrences).

The incompatibility of this circle with scientific methodology may perhaps be illustrated as follows. Suppose a zoologist suddenly announces that five species of a genus of animals must be distinguished, and not just two as has been done so far. He then gives a definitional description of the five species, adding a brief description of animals of the five species. Now, any zoologist interested in testing the five-species hypothesis would probably request specimens of animals classified into the five classes, or at least descriptions sufficiently precise and elaborated for him to make a decision about subsumability. He would most emphatically reject the possibility of verification by interpreting the words used in descriptions of specimens in the light of the five-species hypothesis. Let us suppose the description of a specimen of species number 4 includes the vague phrase «very long bones» and that the testing zoologist finds fifty senses of the phrase that, if one of them were intended, would support subsumability under species number 4, and fifty senses that would not support subsumability. It would undermine zoology as a science if the testing zoologist concluded «Confirmatory instance!» on the basis of the fifty interpretations that make the vague phrase «very long bones» fit the definitional description of species number 4.

Even in the, presumably, most authoritative dictionaries and encyclopedias, it is often not clear whether quoted passages are meant as occurrence sentences that support a synonymity hypothesis or whether they are didactical illustrations. Moreover, when the quotations are clearly to be understood as examples of subsumable occurrences, it is often not clear whether the authors mean that every instance of the quoted expression gives subsumable occurrences or whether the expression only sometimes has the

sense described. If it is only meant that it sometimes has the sense, and sometimes not, it is very difficult to test the hypothesis.

Some lexicographers may be very clear about what they intend, but in no lexica or dictionaries have we so far been able to find fairly precise descriptions of what they intend. This seems to be an important source of the prevailing uncritical attitudes toward «dictionary meanings».

In concluding this chapter, we might once more indicate the nature of subsumption analysis and the difficulties involved in its implementation: the observational material of subsumption analysis is made up of definitoid formulations and occurrences of expressions presumed—on the basis of more or less confirmable and confirmed hypotheses—to fulfill the requirements of being definiendum expressions in the definitoid formulations.

The subsumption analysis consists in attempts to solve in a fairly reliable way questions of the following kind: is the observed occurrence a_1 of a definiendum in conformity with, or in disconformity with, or irrelevant in relation to, the definitoid formulation «b» interpreted in the way «c»?

As a special case, we have the question of whether an author follows his definitions.

From philosophical and other literature one gets the impression that conclusions in the field of subsumption analysis are thought to be easily obtained. By pointing to some of the difficulties encountered in trying to reach conclusions, the preceding sections have perhaps contributed to dispelling that impression.

The next chapter, «Occurrence Analysis», deals with a more comprehensive subject, which includes subsumption analysis. The problem will be: given a set of occurrences of a designation or a sentence, can a usage characterization be found such that it can account for the occurrences as subsumable under the characterization and such that (in certain types of cases) prediction can be made of future occurrences?

The main difference between subsumption analysis and occurrence analysis is that in subsumption analysis we start from given definitoid statements, whereas in occurrence analysis the construction and reconstruction of definitions are part of the job to be done.

VI

Occurrence Analysis

A. Occurrence Analysis Characterized

VI.1. Introduction: Meaning Revealed by Use

It is a valuable slogan that to find the meaning of a term, one should not *ask* about it but observe what people *do* with it. From the use of the term, as observed in concrete situations, the linguist is believed to «see» what it means or to «infer» its meaning by clear-cut methods.

Bronislaw Malinowski, the anthropologist, plunges into the activities of the natives, accompanies them on their fishing trips, listens to their shouts during work requiring cooperation—and he *understands* what they say.¹

Whereas Malinowski sees meanings by enjoying life in the South Pacific, P. W. Bridgman «sees» the meanings of physical terms by looking at physicists handling measuring rods and other laboratory equipment. Bridgman's maxim is also to disregard the explanations that physicists give of their terms and to look closely instead at how they use them, or to observe «which operations they mean». Bridgman and others seem to catch meanings of terms by direct awareness of behavior. There is very seldom any description of *inferences* from described observations of behavior to meanings.

The reasons for not taking ordinary people's or politicians' definitions of terms seriously are too well known to warrant explicit formulation. But there are also well-known reasons not to trust experts. Einstein disregarded Newton's normative definitions of «space» and «time» and studied the use of time and space designations in concrete research situations, especially in situations in which physicists confirm or disconfirm hypotheses involving measurements of time and distance. The transition from analysis of defini-

VI. OCCURRENCE ANALYSIS

tion to analysis of use is a primary concern in analytical philosophy as well as in scientific methodology.

The slogan that to find meanings one should observe what people *do* with terms rather than listen to people's answer to questions about how they use them is valuable insofar as it undermines the belief that we always follow our normative definitions, or always *can* follow our (vague) normative definitions, or always are capable of making tenable descriptive definitions of terms we use.

In this chapter some features of analysis of use are systematically described. First of all, it has been our aim to give explicit form to procedures that so far have been carried out without being described and evaluated as to their validity and presuppositions.

Our aim is to concentrate on cognitive meanings of abstract terms and therefore to develop a technique for constructing and testing descriptive definitions of use. To limit our task to manageable proportions, we shall not discuss ostensive definitions and related problems, but mainly look for meaning by analysis of occurrences of terms in *texts*.

One of the chief imperfections of traditional attempts to find meaning by «seeing how a term is used» is the tendency to keep secret just *which occurrences of the term* are covered by the analysis, and which are the *auxiliary hypotheses* made use of in each case to arrive at the conclusion that a definite occurrence of a term conforms to the adopted definitional description of use.

If, in the future, thorough methods are developed for finding meanings from observation of use, then the insistence on exposition of minor research activity units, such as inferences from quoted individual occurrences, may safely be left out; however, the confused state of affairs in semantics makes broad explicitness a necessary condition for progress.

The importance of connecting hypotheses about usage with definite, quoted, or otherwise described instances of the term whose use is under investigation, has motivated us to call the quest for reliable hypotheses of usage by analysis of occurrences by the name «occurrence analysis».²

VI.2. Natural Occurrences and Artificially Produced Occurrences

The occurrences taken into consideration by lexicographers before they formulate their dictionary meanings are mostly occurrences in printed texts.

The works of some representative authors are gone through and all occurrences of certain terms are listed, usually together with the immediate verbal context.

In the case of slang dictionaries and others dealing with highly fluid language structures, there is a greater tendency to ask users to articulate their meaning: «what do you mean by ---?»; «how do you use ---?»; «is this a word for thief?»; and so on. Or, more indirect methods are used: «how would you translate --- into ---?»; «what do you call this thing ---?»; «what do you see there?»; and so on.

In the latter cases the immediate verbal context, and sometimes the psychological and social situation, is deliberately controlled with a view to producing occurrences of special interest and importance. When occurrences are produced in this way, we shall speak of «artificial» occurrences and distinguish them from «natural» ones.³

In a completely general description of a usage, the cases of artificial occurrences are intended to be covered by the description. There are occurrences that, strictly speaking, are not produced by those who answer questions of the kind mentioned above, but nevertheless are imputed to them. If the analyst asks, «Do «a» and «b» in this text express the same cognitive meaning to you?», and «Yes» is answered, the very short answer is expanded into ««a» and «b» express the same, etc.», and an occurrence of «a» and «b» is put into the occurrence protocol.

If colored papers are placed before a test subject and he is invited to classify and name colors, the answers contain occurrences of color names that profitably can be made the basis of occurrence analysis. That the experiment may be intended for nonsemantical purposes does not preclude the pertinence of occurrence analysis to many conclusions traditionally based on the answers. When in experiments of psychological aesthetics, people are asked which shapes of triangles or other items they «prefer», some differences in answers can be taken as evidence of differing interpretations of «prefer» and other words in the questionnaire. If the respondents had interpreted the crucial terms in the same way, their answers might have been identical. Thus, interpretational differences may in many cases be of importance to the evaluation of conclusions about «which shapes are preferred». It is, however, usually ignored that such conclusions, and similar ones to any questionnaire whatsoever, have their semantical aspects, which, if ignored, render the conclusions scientifically of little value. The

VI. OCCURRENCE ANALYSIS

possibility that differences in answers may be attributable to different interpretations or different solutions of subsumption problems is taken seriously by only a small percentage of researchers using questionnaires.

The analyst presumes that all respondents interpret the questions in the same way that he does. All the advanced techniques by which attempts are made to eliminate this source of error are based on kinds of occurrence analysis. The basic hazards and difficulties of occurrence analysis are implicitly presumed to be mastered.

The use of occurrence analysis in psychological and social science techniques is not illustrated in this chapter. It deals more generally with those basic difficulties of occurrence analysis that must be overcome to make it a reliable tool in all sciences, formal and nonformal, social or nonsocial.

VI.3. Main Steps of a Standard Connotational Occurrence Analysis

1. Identifying and Specifying of Occurrences to Be Analyzed

To make a critical evaluation of methods of occurrence analysis feasible, we need a fairly precise description of possible methods. At this stage of preliminary research in semantics, it is not of prime importance that all details of the described procedures should prove fruitful. The description of details is important only to make sentences about occurrence analysis practically *testable*. It is the requirement of testability that makes us go into details in the following descriptions. We shall describe a procedure that we shall call «standard connotational occurrence analysis». It is meant to function as a sort of reference scheme in relation to which a great number of procedures may be described in a few words by reference to possible modifications of the standard.

Let us suppose that a class of instances of the use of a designation is given in the form of a list. In that list, each occurrence is numbered occ. 1 to occ. n and distinguished by a quotation giving the immediate verbal context, or by some details of the nonverbal situation. Somehow, the class of occurrences must be delimited in a way that makes it possible for different analysts to study the same occurrences. This is very simple if, for example, we can define the class as «the class of occurrences of the designations

«*demokratisch*» and «*Demokratic*» in the collected works (edition specified) of Karl Marx». To ensure that different researchers have their attention concentrated on the same occurrences, it is convenient to use a numbered list or card index of occurrences, regarded as complete. In the following, we presuppose that the occurrences made use of in a standard analysis are numbered. In Norway there is a card index covering all instances of all words used by Ibsen in his complete works. A great number of similar occurrence collections are available in various countries, but few are of interest to those studying technical terms and cognitive meanings rather than all kinds of functions of all kinds of words.

In jurisprudence it is often important to know where to find every occurrence of a certain term or expression that has been produced by certain individuals or institutions. Seldom, however, are complete descriptive definitions of use sought. It is usually sufficient to establish narrow subsumability hypotheses, a much less difficult task. Suppose there is a controversy about whether an action A is a case of 'murder'. If a defendant can convince the court that any acceptable use of «murder» is such that every act called an act of murder has the property B, and if he can also convince the court that A does not have the property B, then there is no need for the defendant to go into further analysis of use. It is of no use for him to try to convince anyone that a certain complete descriptive definition of murder is correct.

It is our view that the *first step* of an acceptable standard connotational occurrence analysis is the orderly arrangement of the class of occurrences to be analyzed.

To many it may seem pedantic to ask for better delimitation of a pretended field of application than that given by names of texts or authors, but expressions such as «Marx's use of the term 'democracy'» and «'democracy' as used in Aristotle's *Politics*, translated by Ross» are difficult to apply in concrete research work. If one attempts to construct easily testable hypotheses about usage on the basis of fairly well defined classes of instances of use, there must be indications about how to decide whether an instance of a term is an instance of a definite author's use.

Let us, as an illustration, suppose that we are interested in analyzing Andrej Y. Vyshinsky's use of the terms «democratic» and «democracy» in his *Law of the Soviet State*, translated by H. W. Babb. The first chapter of that book contains about sixty-five instances of the sequences of letters

VI. OCCURRENCE ANALYSIS

d-e-m-o-c-r-a-c-y and d-e-m-o-c-r-a-t-i-c, but in only about fifty cases should they—as far as I can judge—be classed as use occurrences of these terms. The others are found in quotations, or in other contexts suggesting that they are not meant to represent Vyshinsky's own usage. Thus, disagreement among analysts about his usage may in some instances owe to different rules for delimiting occurrences. This can be avoided by constructing a list of occurrences—a list of references to definite places in a text, or a list of sentences with page references. We have on page 334 offered a list of the latter kind.

2. *Listing Occurrence Implicates*

As a *second step* we take successively the first, second, and so on, occurrence sentences and ask for each, What can be inferred from this sentence, by simple means, about the cognitive meaning of the designation under consideration with a fairly high degree of certainty and without departing appreciably from the author's actual wording? What we answer to this kind of question is formulated under the heading «*occurrence implicates*».⁴

It is necessary in this procedure to take rather unproblematic and simple inferences first, because of the tremendous complexity and disheartening uncertainty of most inferences that are needed to reach reliable descriptive hypotheses of usage.

It is, of course, arbitrary, within certain limits, where we trace the line between implicates in the sense indicated and other inferences. This does not destroy the usefulness, however, of stating whether one views a suggested inference as an occurrence implicate or not. Ultimately, the distinction between occurrence implicates and other inferences is purely heuristic: we claim only that the distinction makes occurrence analysts less likely to succumb to uncritical guesses and the analysis easier to survey, to communicate, and, in practice, to test.

The procedure for formulating a preliminary system of occurrence implicates is most easily surveyed in the case of a more or less isolated text being analyzed, in which there are *n* successive occurrences: occ. 1, occ. 2, . . . , occ. *n*. By isolation, we here refer to (a) a real absence of detailed knowledge of the text's author or public, ignorance of external and internal circumstances of publication, and so on, or (b) a methodologically motivated decision to limit

argumentation (ad hoc or indefinitely) to arguments based on the text in more or less complete isolation from special information about the nonverbal context, and from verbal contexts other than the text itself. In the following discussion, for reasons of simplicity, the sentences that describe procedures refer to isolated texts, if nothing else is explicitly mentioned.

Let us consider some examples of kinds of inferences and their formulation:

Designations: democracy, democratic. Text: Vyshinsky, *The Law the Soviet State* (1948), translated by H. W. Babb. Occurrence: no. 21, page 43. Quotation from the context:

The essential and fundamental preeminence of Soviet democracy [occ. 20] consists in the fact that for the first time in history the nation itself truly carries state government into effect in its own interest, depriving exploiters of all their privileges and advantages. Herein is also the fundamental feature of Soviet State order (the only truly democratic [occ. 21] order) guaranteeing the satisfaction of all demands and needs, of all the interests and requirements of the popular masses of toilers.

Some suggestions for implicatures based on occurrence sentence 21:

1. As used at occ. 21 by the author of the text, the term «democratic» expresses something that makes it meaningful to say about a state order—in the author's sense of «static order»—that it is truly democratic, or that it is not truly democratic, or that it is democratic, or that it is not democratic.
2. As used at occ. 21 by the author of the text, all state orders except one are subsumable under the class 'not truly democratic state order'. Or, more accurately: as used at occ. 21 by the author of the text, the expression «state order» denotes—on the basis of the opinions Vyshinsky entertains about state orders—things that, with the exception of one, are subsumable under the class 'not truly democratic state order'.
3. As used at occ. 21 by the author of the text, «democratic» expresses something that makes it meaningful to say, «Soviet state order—in the author's sense of «state order»—is a truly democratic order» and «Soviet state order is not a truly democratic order».⁵

VI. OCCURRENCE ANALYSIS

4. As «democratic» is used at occ. 21, it is not only meaningful, but also expresses a tenable assertion according to the author to say that «Soviet state order is a truly democratic order»—on the basis of those opinions that the author entertains about what he calls «the Soviet state order». (The last phrase is of importance because Vyshinsky's assertion about the democraticity of the Soviet state order depends both on his usage and on his theory about how things are in the Soviet state. These two factors must in occurrence analysis be kept apart as clearly as possible.)
5. The signification of the term «democratic», as interpreted at occ. 21 by the sender Vyshinsky, and the opinions on state orders entertained by him are such that it is possible for one and the same state order—in the sense of the author—to have the two properties (a) being truly democratic in the sense of the author, and (b) guaranteeing the satisfaction of all demands and needs, of all the interests and requirements of the popular masses of toilers (all the terms being taken in the sense of the author).

The use of the expression «truly democratic» in occurrence sentence 21 is problematic: it is possible that it expresses a concept with the conceptual characteristics of 'democratic' plus some additional ones, or, that 'truly democratic' and 'democratic' each have at least one conceptual characteristic that the other does not have. In that case there may be truly democratic things that are not democratic, and there may be things found to be democratic that would not be truly democratic if certain additional characteristics were found. In the above implicates, it is assumed that if something, in the terminology of Vyshinsky, may be called «truly democratic», it might also (without logical contradiction) have been called «democratic».

It is tempting to infer from occurrence sentence 21 a closer relation between the two properties distinguished in implicate 5, but it is found convenient in a preliminary list of implicates only to include moderately reliable ones. A closer relation may be inferred from the total context comprising occurrence sentences 20 and 21.

The five implicates are all made on the basis of occurrence sentence 21. Other occurrences are not used in the premises of the implicates, nor is

special information used that could make the conclusions more precise or elaborate.

An indefinite number of inferences other than the listed ones might be added by careful analysis of all that Vyshinsky has said about subjects mentioned in the references. Thus, to implicate 1 might be added an accurate description of state orders on the basis of available information about Vyshinsky's opinions on state orders. According to implicate 1, state orders belong to the class of things that may be «democratic» in the sense of «democratic» intended at occ. 21. Thus, a description of Vyshinsky's classification of state orders is (if implicate 1 is valid) relevant to any hypotheses about the cognitive meaning of Vyshinsky's assertions of the type «x is democratic».

Similarly, Vyshinsky's opinions (at the moment of his sending occ. 21) about the Soviet state order are relevant in efforts to elaborate implicate 4. Just this richness in relevant issues makes it advisable to proceed from the narrower, more easily surveyable sources of information to the broader, less easily surveyable and describable sources. Therefore, step 2 in our procedure is delimited to the listing of occurrence implicates. If it is not, analysts can make no effective collective effort to arrive at well-established, precisely formulated hypotheses about usage.

Indirectly, any kind of knowledge may turn out to be important for the establishment of a descriptive definition. Therefore, if such a definition is put forth as valid without specification of sources of information, the immense fields of observations that possibly could confirm or disconfirm it are relevant to its evaluation. If two analysts arrive at incompatible conclusions about Vyshinsky's use of the term «democratic», it is of prime importance to rapid progress of research on the subject that the analysts can and do specify their premises and sources of information. As such a specification is particularly easy in the case of close inferences from occurrence sentences, we suggest that implicates be made to occupy a prominent place in a preliminary system of occurrence inferences.

The above-formulated inferences from occurrence sentence 21 seem to be sufficiently closely related to the sentence to warrant their classification as implicates. At a mature stage of the development of occurrence analysis, there will be room for a more precise classification of inferences based on a classification of the kinds of premises used.

VI. OCCURRENCE ANALYSIS

The listed formulations expressing the implicates from occ. 21 are all sentences with similar conditions listed. Standardized implicates can be formulated thus:

«At occurrence number x of the term «a», the author intends by the term something that makes --- subsumable under 'a', provided «---» is interpreted as does the author and provided he does not make false subsumption inferences».⁶

The cumbersome repetition of references to the author's usage at occurrence number x, and to the author's opinions about things denoted by certain terms, makes it convenient to abbreviate the occurrence implicate sentences.

Reformulated and abbreviated, the class of implicates from occ. 21 runs as follows:

- i₁: A state order may be democratic or it may not.
- i₂: There is only one truly democratic state order.
- i₃: The Soviet state order is a truly democratic order.
- i₄: A democratic state order may have the property of guaranteeing the satisfaction of all demands and needs, of all the interests and requirements of the popular masses of toilers.

If we are to avoid far-reaching misunderstandings and untenable implicates, it is of paramount importance to remember that these formulations are abbreviations by which essential references are left out.

Implicates 4 and 5 are here given the labels i₃ and i₄, because inference 3 has not been found sufficiently certain and interesting to be included in the definitive version of implicates of occ. 21.

The reason for the omission is not that number 3 is implied by number 4. If one or more implicates within a class are implied by another of the same class, this is not a sufficient reason to eliminate the weaker ones and retain the strongest, that is, retain the implicate implying the weaker ones. To make the logical relations—especially the consistency—between implicates of different occurrence classes easily surveyable, it is safe to split strong implicates into a series of weak ones, the conjunction of which is equivalent to the strong one. This does not, however, make it superfluous

to state the strong implicate. It is a bit of inferred information that has a stronger foundation in observation than an equivalent sentence constructed by weaker sentences if these are the only implicates at hand.

If the occurrence analysis is limited to a study of instances of a designation or sentence within a given text, the second analytical step is completed when, for each occurrence, there is listed a class for implicates.

It might be objected that the standard connotational occurrence analysis, as described so far, attaches too much importance to occurrences of the term investigated as compared with other words of the surveyed text.

This objection would be well founded if the number of sentences we, here in this exposition, use to describe the technique of implicate construction on the basis of occurrence sentences were to be taken as the measure of their importance. Actually, considerations of testability have made us stress the details of implicate construction on the basis of such sentences. As long as the ultimate goal is to construct valid descriptive definitions of usage, no other sentences than occurrence sentences are relevant except indirectly. If a text about democracy includes the occurrence sentence «Democracy is the rule by the people», a descriptive definition of «democracy» may conceivably be chiefly based on ninety-nine sentences containing the word «people» and only the quoted one containing an occurrence of the term «democracy». The relevance, however, of the ninety-nine other sentences is completely dependent on the one occurrence sentence. If that particular sentence had not been in the text, the connection between the use of the term «people» and that of «democracy» would no longer exist. The ninety-nine sentences would have no validating power whatsoever in relation to hypotheses about the use of «democracy».

Thus, the occurrence sentences occupy a unique position among the sentences of a text being surveyed. This should not lead, however, to an exaggerated view about the amount of evidence that can be collected without taking other sentences into account. The latter sentences may turn out to be far more important, but their importance owes to what we find formulated in the occurrence sentences.

If we were to turn away from descriptive hypotheses regarding the use of terms, and were to study the use of concepts, then occurrences of specific concept designations would not have a unique position. In that case, any term expressing the same concept would be equally relevant.

VI. OCCURRENCE ANALYSIS

3. *Interpreting Occurrence Implicates and Constructing Other Inferences*

An occurrence sentence may give rise to various conflicting, but plausible, interpretations. The translation into the vocabulary of the analyst and his readers implies use of interpersonal synonymity hypotheses. Observations and theories from the most dissimilar fields may be of importance to their tenability. This explains our stress on making an implicate list before interpersonal synonymity hypotheses are put forth. By making that list, we survey the context as a whole, and we concentrate our attention on the language of the author. Precocious hypotheses about exactly *what* the author intends to say easily develop into prejudices. Interpretation of implicates ought to be a third step of analysis, after one has been through the text at least once. Possibilities of interpretations are considered in reference to the text as a whole and to the implicate list.⁷

Let us consider the fifth occurrence sentence in Zaslavski's *La démocratie soviétique* (1946–47: 20):

Le régime soviétique est démocratique sous tous ses aspects, y compris son aspect économique.

An implicate:

1. Regimes may be classed into democratic and nondemocratic ones.

It might also be formulated that «Some or all democracies are regimes», but scarcely that «All democracies are regimes».

The last formulation furnishes us with a genus definition (see chapter 4, page 163). On the other hand, it presupposes that the transition from «democratic» to «democracy» is justifiable.

How is implicate 1 to be interpreted? The wording is in part borrowed from Zaslavski—from him stems the word «regime»—and in part we have used our own expressions.

Some difficulties arise from *uncertainty regarding how to interpret the sentence schema* consisting of all words of the occurrence sentence except the designation to be analyzed. The possibility must be reckoned with that two or more different interpretations T_1, T_2, \dots of each occurrence sentence,

A.VI.3. *Main Steps of a Standard Connotational Occurrence Analysis*

T_0 , have to be considered separately. Two or more corresponding classes of inferences should then be formulated for each occurrence sentence.

i_1 of T_1	i_1 of T_2	---
i_2 of T_1	i_2 of T_2	---
---	---	---

If most inferences of the various classes are identical or very closely connected, then the common or nearly common inferences may be retained in one class and the rest ignored. If inferences vary widely, the total class of classes may be unsurveyable, or at least it may be unfruitful to try to formulate it in detail.

If inferences are to be formulated in such a way that the analyst attributes a fairly precise meaning to them, this normally requires extensive re-formulation and elimination of terms used by the sender of the text. In implicate 1 the term «regime» is basic, but personally (as analyst) I do not attach a definite meaning to the term. An inference formulation that expresses a sufficiently precise meaning to me cannot contain the word «regime» as it occurs in implicate 1. If I eliminate the term, however, I must do so on the basis of solutions to the problem of how to interpret the sender of the text.

What does Zaslavski mean by a «regime»? This word as used by Zaslavski is ambiguous, and for each plausible strong precization, I would have to formulate specific inferences. On the one hand, a regime may be identified with a particular government; on the other hand, forms of government may be meant.⁸ Even forms of government and governmental practice may be meant («ancien régime»), so far as I know. The terms «government» and «form of government» are highly ambiguous and require elimination.

Ultimately, an occurrence analysis should furnish the analyst with inference classes containing formulations that are as precise as can be constructed without assuming a depth of intention that transgresses that of the sender. It is probably unwise, however, to try to map out directions of precization the first time a text is studied. The possibilities of precization are so manifold at the initial stages of study that one would be overwhelmed by inferences derived from different interpretations of one and the same implicate.

VI. OCCURRENCE ANALYSIS

The following rules are suggested:

1. The text author's expressions used in implicate formulations contained in the preliminary list of implicates are to be interpreted (by the analyst and his readers) as if *used by the author* of the text.
2. Inference formulations contained in the definitive surveys of inferences are to be interpreted in conformity with the *usage of the analyst*.

The latter rule does not (of course) imply that the analyst may indulge in his own terminological idiosyncracies: he should formulate the inferences in such a way that there is maximum likelihood that readers of the analysis who have been informed about the rule interpret the inferences as does the analyst himself. The reader of the occurrence analysis may therefore legitimately reason as follows: «if the analyst is competent, his wording of this sentence is such that I should be able to understand it as he intends—if I can class myself as a reader with such interpretational dispositions as are foreseen by a competent analyst».

It is not necessary for the analyst to interpret the system of implicate formulations with greater definiteness of intention than is required to justify their being inferred from the occurrence sentence. Because it is a characteristic of the implicate that it can be derived fairly simply, the amount of interpretation should be very small. A method of interpretational suspension is convenient and justified. To take an example: if an occurrence sentence reads, «What Smith says is perfectly correct; all democracies are colorless», I would not hesitate to construct the (abbreviated) implicate sentence «Democracies are colorless». This I would do in the preliminary implicate survey even if I had only vague ideas about what the text's author might mean by such a phrase—if *anything*.

It has in the foregoing been stated that the definitive system of inference classes should provide the analyst with formulations that are as precise as possible—within the limits of the depth of intention of the author of the text analyzed. In this respect, the aspirations of the occurrence analyst are different from those of the analyst trying to construct connotational or denotational explications (cf. chapter 2, section 3), or explications in the sense of Carnap (1950: chapter 1), or formalizations in the sense of Woodger (1939).

Systems of inferences in occurrence analysis are systems of purely descriptive, historical, biographical assertions. Written in full, an inference about the term analyzed is formulated so as to show this character: «as used at occ. i by the author x, the designation «a» expresses ---». Assertions of the kind

Syn (aP₁S₁, bP₂S₂)

are all of the biographical kind, provided P₁ and P₂ are specific individuals or groups.

The constructor of explications and formalizations needs occurrence analysis—but his final product has a normative character: the «definition» he gives may express a usage not exemplified in the past by anybody; it is a construct that may in the future prove convenient or not. Very often, it proves inconvenient or impossible to use, because, after all, to be used the definiens must somehow be connected with the vernacular. If the connection is such that vague and ambiguous phrases are used to explain the intended rules of use, then the explication or formalization may be misleading. Different researchers may easily get inconsistent results because of different interpretations of «*Zuordnungsdefinitionen*».

The very difficult task of going from the formulation of a preliminary system of implicates to the establishment of a definitive system is necessary to provide connecting sentences between explication or formalization and the vernacular or the nonformalized technical jargon of a scientific discipline.

So far, we have discussed the translation of occurrence implicates into the language of the analyst. During this stage of the work, it is convenient also to note any inferences from the occurrence sentences that have not led to occurrence implicates because of their uncertain or free character. Let us consider another passage from Zaslavski's *La démocratie soviétique* (1946–47: 33):

Démocratie [occ. 70] est le pouvoir du peuple. La démocratie [occ. 71] est l'antithèse de l'aristocratie, du pouvoir des nobles. La démocratie [occ. 72] est aussi l'antithèse de la ploutocratie, du pouvoir des riches.

Suggested inferences:

VI. OCCURRENCE ANALYSIS

1. A democracy in the sense of Zaslavski cannot possibly be identical with a society in which the nobles—in a sense of «nobility» used in bourgeois countries—have the decisive political power.
2. A democracy in the sense of Zaslavski cannot possibly be identical with a society in which the rich have the decisive political power.

These inferences are of some interest. They are too uncertain, however, to be classified as «implicates» and cannot be included in the preliminary implicate list. They are rather *interpretations* of the occurrence sentences that are inferred on the basis of uncertain hypotheses about what Zaslavski means by «antithesis», an important word in Marxist doctrines.

Now we turn our attention from the inferences explicitly based on occurrence sentences. The special properties of the occurrence implicates (see page 306) warrant discussion before other inferences are developed systematically. It is now convenient to note any inference whatsoever—short of complete descriptive definitions—that can be drawn from analysis of sentences in the text, whether those sentences are occurrence sentences or not.

The passage from Zaslavski quoted above strongly suggests the relevance for the analysis of the word «democracy» of inferences from sentences containing such words as «people» and «power». The following inferences from sentences in Zaslavski, page 33, are therefore important:

1. It was the people who exercised the power in the Athenian Republic.
2. The people exercise the power if the people have the custom of assembling at a public place and their representatives make decisions about the administration of the state by means of consultation and votes.

Figure 4 illustrates the step-by-step widening of the scope of analysis. Analytical step 4 is discussed in the next section (see page 319).

VI.4. Consistency Problems

The review of inference formulations in the light of the total context may result in reinterpretation of occurrence sentences and implicates and modification of inference classes. The theory of interpretational vibrations caused by broadening the context is relevant here (see chapter 2, section 13).

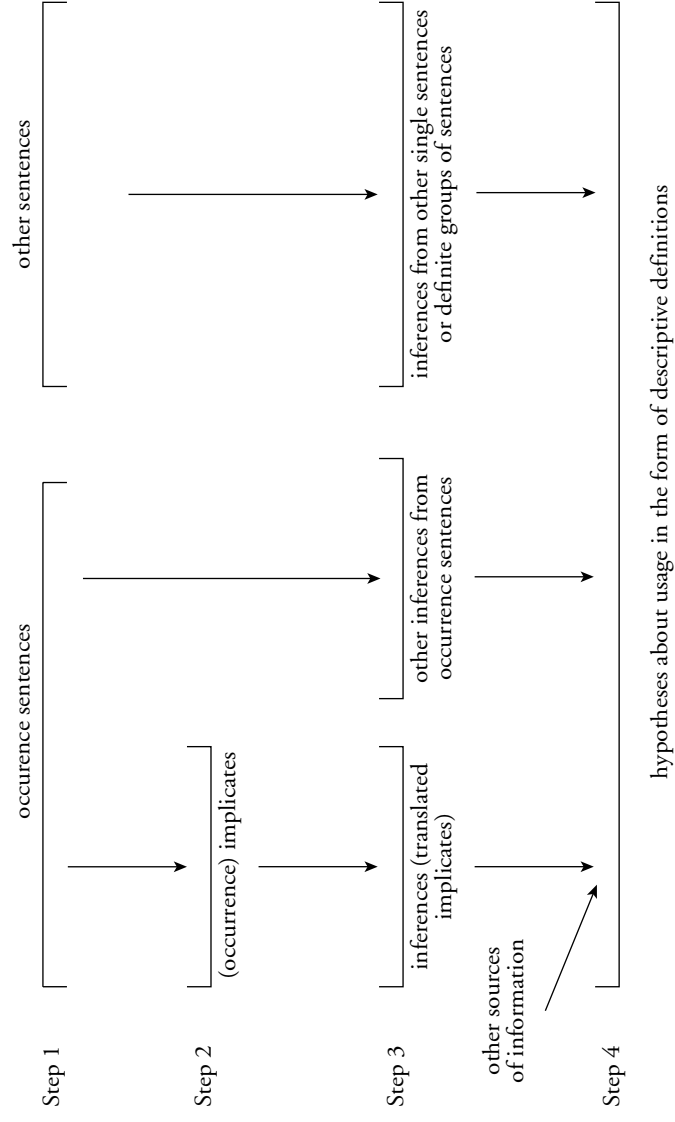

Figure 4. Steps in connotational occurrence analysis.

VI. OCCURRENCE ANALYSIS

As soon as more than one of an author's sentences have been translated into the vocabulary of the analyst and his readers, a new set of problems can be attacked: that of the internal coherence and consistency of a set of assertions. Can they be integrated into a consistent doctrine? What are the relations within the total body of assertions made by the author? The result of inquiries into consistency and coherence may be such that initial translations are doubted and new ones attempted. The total body of assertions changes for every reinterpretation and creates fresh consistency problems.

Logical or empirical (synthetical) inconsistencies (see chapter 5, section 8) between conclusions in inferences from the implicates or directly from occurrence sentences are of some importance. Suppose a designation at its occ. *i* is used in such a way that an assertion 'a' seems to be implied, but 'non-a' seems to be implied by occ. *j*; that is, suppose there seems to be a logical inconsistency implied by the joint assertion of two parts of the same text. This may be taken as a symptom of

1. use of the designation at occ. *i* in a sense different from any that would imply 'a' or use at occ. *j* in such a way that 'non-a' is not implied, or
2. untenable auxiliary hypotheses used by the analyst, or
3. logical inconsistency on the part of the author.

If the weight of the evidence supports symptom 2 better than it supports symptoms 1 and 3, a revision of the system of inferences is called for. The new system may, of course, contain fresh inconsistencies, but we may safely assume that repeated reviews will decrease their number and seriousness.

If symptom 1 seems most probable, and thus the author seems to be using a designation in two ways, this makes it necessary to construct two descriptive definitions to be used in the next version of the translated occurrence sentences.

By empirical inconsistencies we refer to the appearance of two (logically consistent) implicates 'a' and 'b' of such a kind that there is a body of assertions 'c' (presumably) adhered to by the author as a body of empirically tenable assertions, and this body of assertions makes 'a&c' logically inconsistent with 'b', and 'b&c' logically inconsistent with 'a'. for example:

Implicate 'a':	No monarchy can be democratic.
Implicate 'b':	Norway is democratic.
Assertion 'c':	Norway is a monarchy.

Examples of assertions cannot be given without using sentences. In the above example, «Implicate 'a': No monarchy can be democratic» can be read as «implicate 'a': the assertion that the analyst expresses by the implicate sentence «No monarchy can be democratic»».

If, and only if, one may assume that the author of the text at the time of formulating the occurrence sentences entertained the opinion that Norway was a monarchy, then there is empirical inconsistency between the implicates 'a' and 'b': they cannot both as conceived by the author analyzed.⁹

Empirical inconsistencies may be taken as symptoms of the three conditions mentioned. There is, however, the additional source of uncertainty represented by the assertion 'c': Is it safe to assume that the author believed in 'c' when writing the occurrence sentences from which 'a' and 'b' are derived? How do we know?

In the above exemplification of 'a' and 'b', the expression «a» for 'a' is not satisfactory as a member of the definitive system of inference sentences. In the preliminary system, it may be useful, in spite of the ambiguities of «monarchy»; but in the definitive one, it is important to know whether, for example, «limited (constitutional) or unlimited monarchy» is meant by the analyst, or maybe «unlimited monarchy». If 'a' is reexpressed as «No unlimited monarchy can be democratic», and 'c' is reexpressed as «Norway is a constitutional monarchy», no synthetical inconsistency arises.

The definitive system of inference classes ought to be arranged in such a way that internally consistent classes can easily be surveyed and thus made the basis for construction of hypotheses about usage in the form of descriptive definitions.

4. Forming and Testing Hypotheses About Usage in the Form of Descriptive Definitions

An occurrence analysis is called «connotational» if the final step is an attempt to establish complete hypotheses of use in the form of descriptive definitions. Such hypotheses may, for example, have the following form:

VI. OCCURRENCE ANALYSIS

«The author N. N. uses the designation T_0 to mean the same as:

1. T_1 when using T_0 at occurrence numbers --- of the text F,
2. T_2 when using T_0 at occurrence numbers --- of the text F, etc.»

The designations T_1, T_2, \dots are here definiens formulations of descriptive definitions, with T_0 as definiendum and a certain class of occurrences as the intended field of application.

As an example of hypotheses of use that are not in the form of descriptive definitions, and therefore are not representative of conclusions in connotational occurrence analysis, we mention the following genus definition sentence:

«Aristotle used the designation «democracy» to mean a kind of government, not a kind of society».

By such a sentence something is asserted about the use of a term, but not in the form of a descriptive definition. Nothing is said about what kind of government «democracy» is used to designate.

The tentative descriptive definitions are, in principle, guesses or assumptions guided by the implicates and whatever evidence is at hand, and not sentences derivable by logic from the system of implicates or from any established theory of human verbal behavior. To «see» that a designation or sentence is used in a certain sense by «looking at» the context is a metaphor that well depicts a common attitude of optimism in matters of semantics. It stems perhaps from the frequent cases in which we are pretty sure that either T_1 or T_2 is meant by T_0 ; no other possibilities may be expected. Any symptom that T_1 cannot be meant will in that case make us postulate that T_2 is the correct interpretation. The general situation is usually such that no great level of preciseness is required. Occurrence analysis is, on the other hand, first, an instrument by which to find out about cognitive meanings without presuming to already know approximately where to find the solution, and second, an instrument by which to test tentative solutions derived by mere guessing.

Against the thesis that there is never a relation of strict or material implication between classes of implicates of occurrence sentences and descriptive definitions, two objections deserve to be mentioned. The first may be phrased as follows:

«If a man introduces a normative definition of a designation and pro-

claims all his future texts to be the field of application, he may well forget his intention and violate his own definition the next moment. But in the definition itself he at least uses the designation as defined. Thus, from the occurrence sentence consisting of the normative definition itself, the appropriate descriptive definition can be inferred without chance of error—the definiens of the descriptive definition that solves the problems of the occurrence analysis under the specified conditions is the definiens of the normative definition.»

Our answer is: If a person introduces a normative definition by which a T_0 is defined by a T_1 (the definiens), the occurrence of T_0 as definiendum in the normative definition is not an instance of T_0 being «used», but of T_0 being talked about. It belongs to the metalanguage. If T_0 in the normative definition were intended to be interpreted as T_1 , the normative definition would be the rather trivial «By T_1 I shall in the future mean T_1 ».

A second objection runs as follows: «Suppose an author intends by the designation «the Scandinavian countries» to express the same as «the countries Sweden, Denmark, and Norway» within a given context. Now, if the implicates found by occurrence analysis are «Sweden is a Scandinavian country», «Denmark is a Scandinavian country», «Norway is a Scandinavian country», and «There are three and only three Scandinavian countries», then the definiens of the correct descriptive definition is *derivable* from the conjunction of the implicates».

It is admitted that if I had the above system of four implicates, I would be very sure that «the Scandinavian countries» was used as mentioned. It is important to note, however, that my conviction would not stem from inspection of the system of four implicates. These four implicates are also compatible with the assumption that the author by the designation «the Scandinavian countries» meant «countries the kings of which were in 1940 more than six feet tall» or «constitutional monarchies the most southern points of which are more than 50° north of the equator».

There are also other considerations that throw light on the untenability of the objection and its basic misconceptions. The so-called «implicates» of the last sections are—as mentioned—not implicates in any of the senses of modern logic. From the implicate «Sweden is a Scandinavian country», nothing about the *intention of the author* of the occurrence sentence can be derived. Whatever I say, it cannot *by logic alone* be inferred what

VI. OCCURRENCE ANALYSIS

I intend by my words. To avoid some of the misconceptions that arise from underestimating the distance in meaning between conjunction of occurrence implicates and descriptive definitions, we must bear in mind that the usual manner of formulating those implicates owes to an abbreviation of rather complex formulations (see pages 309–10).

For many purposes it is of slight importance to know exactly what an author intended (if anything at all). In that case one may close the occurrence analysis when it is found that all descriptive definitions of a certain class of similar definitions are consistent with all the occurrences under investigation.

Let us take an example just to illustrate how we need occurrence analysis to find a class of descriptive definitions consistent with the occurrences in a text. Suppose we are interested in the creation of a fairly exact introduction to the mathematical theory of matrices. By «matrices» we do not need to mean anything very definite at the initial stages of the investigation. We simply begin reading various mathematical texts that claim to deal with matrices. Among the many authoritative texts, we find the work of Frazer, Duncan, and Collars (1938). One of our problems will be, Should we accept these authors' concept as the most exact and fruitful basic concept of our own account? One of the first things to do, then, is to see how the authors explicitly define «matrix». The work opens with a sentence that strongly suggests a normative definition:¹⁰ «[m]atrices are sets of numbers or other elements which are arranged in rows and columns as in a double entry table and which obey certain rules of addition and multiplication» (ibid., p. 1).

There are no other sentences that suggest a normative definition. The sentence, whether intended as a normative definition or not, would probably suggest to many readers that the simplest matrix would be one in which there were just enough elements to allow a distinction between vertical and horizontal arrangement. This would suggest an arrangement with four elements, such as (1) below, or an arrangement with three elements.

Readers who from the quoted sentence inferred that the authors intend to use the expression «rows and columns» in such a way that one may in every matrix distinguish rows from columns, would get into difficulties of interpretation when they reached page 2 of the text. There the authors speak about «a matrix with only a single row of elements». A matrix with

only one column of elements is also mentioned (*ibid.*, p. 2). Now, the plural in the introductory sentence («rows and columns») might plausibly be interpreted to imply that any set of elements consisting of fewer than two rows and two columns could not possibly be a matrix. The occurrences on page 2, however, strongly suggest an interpretation such as «A matrix is a set of elements arranged in rows or columns or both (and in that case as in a double entry table)—the limiting case being one row or one column, ---».

The following sets of elements would then be matrices in the sense suggested by the occurrences on page 2:

$$\begin{array}{lll} \text{(1)} & \begin{array}{l} a_1 \ b_1 \\ a_2 \ b_2 \end{array} & \text{(2)} \quad a_1 \ b_1 \qquad \text{(3)} \quad \begin{array}{l} a_1 \\ b_1 \end{array} \end{array}$$

Case (1) would also be a matrix in the sense suggested on page 1, with $a_1 \ b_1$ and $a_2 \ b_2$ being two rows, and $a_1 \ a_2$ and $b_1 \ b_2$ being two columns.

On page 6, however, the authors state that a certain «product» of two matrices is a matrix with only one row and one column and being identified with only one element, for example, identical with the element a_2 in matrix (1). A single element like a_2 is, according to what is said on page 6, a matrix. To speak of this single element as being arranged in a row or a column goes against the usage suggested by the opening sentence. The occurrences of «matrix» on pages 2 and 6 are such that no normative definition that is supposed to cover those occurrences can imply the possibility of a distinction between row and column within any matrix.

From these occurrences on pages 2 and 6, we conclude: on the assumption that the introductory sentence is a formulation of a normative definition with the whole text as part of its intended field of application, the introductory sentence is an example of a formulation that for some plausible interpretations furnishes normative definitions *not* consistently followed in the intended field of application.

In such a case, an occurrence analysis is warranted, which can result in descriptive definitions such that all or nearly all occurrences of the text are subsumable. The construction of a suitable normative definition proceeds on the basis of descriptive definitions obtained by occurrence analysis. In the above example, a mere glance at the occurrences on pages 2 and 6 of the text probably suffices, for readers accustomed to mathematical devices

VI. OCCURRENCE ANALYSIS

of concept formation, to make them infer that the authors intend a concept 'matrix' of a rather broad kind. No elaborate occurrence analysis is called for.

It is common to undertake an analysis with a prejudgment in favor of normative definitions that *resemble as closely as possible the unfollowed one*. Not making such a prejudgment leads to complicated observations and inferences as described in the exposition of the standard connotional occurrence analysis.

The shortened analysis does not differ from an ordinary subsumption analysis in other respects than that modified definitions are constructed on the basis of the definition originally given.

Now, if our task is to formulate a fairly exact account of matrices, we shall probably try to make the account include most or all sentences in the cited text dealing with properties of matrices of various kinds. There is no chance, however, that occurrence analysis will be able to furnish a concept of matrix implied by the occurrence sentences. It is, for example, possible to use (a) a concept by which rules of multiplication of matrices are contained in the concept of matrices as conceptual characteristics, or (b) a concept by which such rules are not part of the concept. Further, it is possible to use (c) a concept such that inkblots may be elements of matrices, or (d) a concept such that inkblots cannot be elements.

All theorems in the cited work can—as far as I understand it—be retained as theorems in accounts that have such different concepts at base. Frazer, Duncan, and Collars themselves introduce a very general concept as regards what can be elements (including inkblots), but they offer no theorem about kinds of elements other than numbers and, perhaps, letters.

Inspection of the definitive system of inferences suggests to the analyst the direction in which adequate descriptive definitions may be found. He will tentatively formulate such definitions and try to test formulations. The test consists in trying to determine whether the occurrences are subsumable under the descriptive definition, that is, whether the definition «suits» the instances intended to be covered. One must take each occurrence sentence, use the implicates with their translations, and substitute the definiens of the descriptive definition for the definiendum occurrence. Such a test is, of course, not independent of the assumptions made at the first steps of occurrence analysis. It can only help the analyst, because he

A.VI.5. *Relation Between Practical Testability and Intended Field of Application*

usually cannot have all occurrences in mind when framing the tentative descriptive definitions.

The questions of subsuming instances under the definiens of tentative definitions are those of subsumption analysis mentioned in chapter 5, part C. Subsumption analysis is, in other words, one of the tools of connotational occurrence analysis.

The first steps of occurrence analysis are, on the other hand, necessary steps in subsumption analysis, if we ask for subsumability of a series of occurrences of an expression. The differences between connotational occurrence analysis and subsumption analysis may be formulated thus:

1. Subsumption analysis starts with an explicitly formulated normative or descriptive definition that is *given in advance*. Occurrence analysis starts with occurrences and aims at well-founded descriptive hypotheses that are not given but must be constructed.
2. In both subsumption analysis and connotational occurrence analysis, the examination of occurrences normally results in either confirmation or disconfirmation. If the verdict is disconfirmation, subsumption analysis ends, whereas the next step in occurrence analysis is the search for a modified descriptive definition that is not disconfirmed in relation to the occurrence.
3. In subsumption analysis, a conclusion that all occurrences under consideration are subsumable is an ultimate conclusion. In connotational occurrence analysis, the conclusion that all descriptive definitions of a certain class are equally warranted is not an ultimate conclusion. There is still the question, Which occurrence, if any, expresses the intended use of the text's author?¹¹

VI.5. Relation Between Practical Testability and the Extent of a Hypothesis's Intended Field of Application

If a hypothesis about the use of a term, let us say a descriptive definition of the use of the term «democratic», is so formed that its intended field of application comprises all occurrences up to 1950, it can, in principle, be confirmed or disconfirmed in relation to a vast number of occurrences. If, on

VI. OCCURRENCE ANALYSIS

the other hand, the descriptive definition's intended field of application is narrowed down to only one occurrence, let us say to occ. 5 in Zaslavski's text, the practical possibility of testing it is limited to this occurrence, which is only an infinitesimal fraction of all occurrences up to 1950. The vulnerability of the descriptive definition is in this case very much smaller, but so also is its capability of being confirmed. Normally, the test will prove inconclusive because of lack of evidence.

If we try to test a descriptive definition on the basis of a very small number of occurrences, it is highly probable that we shall succumb to the temptation to use as auxiliary hypotheses conclusions obtained from acquaintance with other occurrences. The limitation of occurrence analysis to a definite set of occurrences is very difficult to carry through, and it is utopian to believe in strong confirmations or disconfirmations on its basis. Consider the student of so-called national character. He may *pretend* to base his conclusions on definite tests applied to a small number of people, whereas he in practice largely bases them on general impressions and on current stereotypes concerning the alleged national character.

For methodological reasons, hypotheses intended to cover a large group of occurrences are preferred (other things being equal) to hypotheses covering a small group, because of *the greater testability* of the former.

Suppose a text contains 200 occurrences of «a», and two hypotheses are put forth, one covering all occurrences, another covering only a part. There is a greater chance of building up occurrence inferences suggesting descriptive definitions by means of all occurrences than by means of a part. Thus, there is more material by which to test a descriptive definition claiming to cover all occurrences.

Suppose, however, as is done in the case of occ. 5 in Zaslavski's text (see page 312), that there is some evidence that «democraticity of the economic aspect» means «openness to inspection and discussion of the economic life», and that there is a later occurrence suggesting with the same amount of evidence that the designation at occ. 5 is used in a certain broader sense. Should we then prefer the hypothesis that the expression is used in one sense in both cases or the hypothesis that it is used in two different senses, one narrow and one broad?

The answer would be that *if the evidence is stronger* for the hypothesis implying two senses, then it should be preferred. I do not see, however, that

A.VI.5. *Relation Between Practical Testability and Intended Field of Application*

this can easily be the case, and the explanation is in part found in preceding references to small practical testability. To make the point clearer, we symbolize the amount of evidence by the height of rectangles:

When we prefer the narrow definiens expression «openness to inspection and discussion of the economic life», our preference can be explained, I think, partly by a commonly observed overestimation of the immediate context in judging meanings and partly by expectations derived from occurrences in other texts. The plausibility of this explanation may be illustrated by looking at the following occurrence of the word «steep»:

«Mount Everest is steep. On no mountain is there such a uniformity in the angle of inclination of the rocky slopes».

It would be rash to conclude from the immediate context of the first sentence that the author by «steep» means «uniformity of inclination of angle», and as applied solely to rocky slopes, not to ice. The second sentence is probably not meant to be synonymous with «No mountain is as steep as Mount Everest», which might be inferred if the above rejected hypothesis were tenable. The second sentence would probably have to be taken as an argument supporting a thesis on steepness that is broader than a thesis on the *uniformity* of inclinations of rocky slopes.

VI. OCCURRENCE ANALYSIS

Other examples might be adduced that illustrate how the immediate context can be deceptive and how expectations may easily be overlooked as a factor determining one's judgment of degrees of confirmation. From previous use of «steep» I would tend to expect broader concepts than the one hastily inferred from the immediate context. That makes me not take that context very seriously as an indicator of the meaning of «steep». In the case of the immediate context of the designation «economic aspect of democracy», some analysts may expect meanings close to those suggested by the immediate context, whereas others may recall other occurrences that make them attach low value to the evidence of the immediate context.

An objection might be, How can the above complicated, highly speculative, uncertain argumentations and illustrations be taken as the basis for rejecting one hypothesis of usage as false and accepting a competing one as true? To this it may be answered that there is no question of taking one as true and rejecting others. In the field of elementary analysis, we may try to single out one hypothesis as the *most* tenable among a group of hypotheses, but this does not preclude the requirement that other hypotheses be considered nearly as tenable. In argumentations and plans of actions based on the conclusions, all the hypotheses above a certain level of tenability must be kept in mind. Furthermore, we often lack the necessary basis for picking out one hypothesis as the most tenable within a group, because the components or factors determining tenability are complex, and sometimes only crude oversimplification makes it possible to arrange hypotheses in a one-dimensional order indicating tenability. It must also be borne in mind that, for many practical purposes, we need no clear-cut hypotheses on connotation if many instances of use of the expression are well known to us. We may talk about democracy in a way approved of by our environment without bothering about what the designation means in the sense of connotation.

It might be thought that in occurrence analysis one should first concentrate on finding the meaning of a designation within very small groups of occurrences, and then look for possibilities of meanings common to greater groups. Thus, one would proceed from hypotheses involving the possibility of ambiguity to hypotheses representing attempts to find common meanings that can bridge apparent ambiguities.

The close relation between number of occurrences and practical testa-

bility severely limits such a procedure. On the other hand, the possibility that each new occurrence represents a new sense cannot be ruled out, nor should the possibility be overlooked that the designation under analysis may not have any meanings at all in the sense of cognitive meaning. The designation may have only extracognitive meaning or may be used with such a low definiteness of intention that even rough delimitation of connotations is practically impossible.

VI.6. Limited Choice Analysis

Under the name «limited choice analysis» we shall describe a kind of analysis that is not a standard connotational occurrence analysis, but that can be carried out as a partial or simplified one.

A hypothesis of one of the following kinds is postulated, or accepted on the basis of evidence of one kind or another:

- (1) « T_0 has the connotation T_1 or T_2 or . . . or T_n .»
- (2) « T_0 has the connotation T_1 or T_2 or . . . or T_n or none.»
- (3) « T_0 has a connotation with small or no meaning distance from T_1 or . . . or T_n .»

In short, limited choice analysis proceeds from a postulate or initial assumption about which possibilities are at hand. This causes the analysis ultimately to break up into a *limited* set of subsumption questions, which may all be given the form «Is T_0 subsumable under a descriptive definition with T_a as definiens?»

Let us suppose that a preliminary analysis on the basis of hypothesis (1) gives as result that T_0 is subsumable under both T_1 and T_2 . The weight of evidence is in that case reexamined on the assumption that T_0 has either the connotation T_1 or the connotation T_2 . Any difference in weight will decide the issue. In a standard connotational occurrence analysis, such a simple decision would never be warranted.

Let us, on the other hand, assume that a first analysis on the basis of hypothesis (1) gives as result that T_0 is subsumable under none of the connotations T_1, T_2, \dots, T_n . A reexamination of evidence on the basis that one of them nevertheless *is* the connotation, will tend to justify that one is picked out at least as the one that is most likely to be correct. Such a procedure is

VI. OCCURRENCE ANALYSIS

inconsistent with the principles of standard connotational occurrence analysis. According to those principles, no limited group of possibilities can be postulated.

Much lexicographical work seems to proceed as a limited choice analysis rather than as a standard occurrence analysis. Sometimes explicitly, but usually implicitly, it is taken for granted that T_0 «must» mean something like T_1 or T_2 or . . . T_n .

The possibilities of choice are determined by transformation (translation) hypotheses, syntactical considerations, or hypotheses about which objects have a name. A limited choice analysis may, or may not, in practice be identical with a portion of a complete connotational occurrence analysis. The first steps of an occurrence analysis may suggest choices of definiens expressions used in a limited choice analysis and may help one decide between the alternatives. But as the term «limited choice analysis» is used here, the analyst may not make use of any steps of occurrence analysis, but immediately proceeds to try out subsumptions on a more or less intuitive basis.

I am not suggesting that limited choice procedures are «bad»—only that it is important to make explicit the assumptions or postulates that from the very beginning of the procedure limit its scope. In any analysis, only a limited number of subsumption attempts can be carried through.

Therefore, even in standard occurrence analysis only a limited number of possibilities can be tried out. The difference lies in the fact that, in the complete analysis, no assumptions are made that limit the claim of the conclusions. Compare the following two kinds of tasks: to decide whether a text, *assumed* to be written by either Bacon or Shakespeare, was written by Bacon or was written by Shakespeare; and to decide—without any a priori assumptions about authorship—who has written the text. We can in both cases try out only a limited number of authors, but evidence sufficient to decide the first case may not be sufficient to decide the second with an equal degree of certainty.

Given a group of occurrences, occ. 1–occ. n , of a designation T_2 , let us suppose it is somehow definitively known that all occurrences are occurrences of one and the same connotation T_1 .¹² Whatever the number or kind of occurrences given, there will always be connotations T_2 . . . T_m that are

such that $\text{occ. } 1 - \text{occ. } n$ are subsumable under them. However much we increase m , there will always be a T_{m+1} for which this holds good.

Although there is reason to believe this theorem, it would have to be precized to reach a satisfactory level of practical testability. Efforts to limit the possibilities in standard connotational occurrence analysis, other than by postulating limits, have never succeeded, and I see no reason why they ever should succeed.

The theorem might be called the «*theorem of unlimited possibilities of subsumption*». It is analogous to the theorem that whatever the number of points dotted on a plane surface, as long as the number is finite, there are always infinitely many different curves that can be traced through all the points.

VI.7. Analysis of Single Designation on the Basis of Hypotheses About Structure

To find «the» connotation of a designation by occurrence analysis, one must—even in the case of «pointings» («*This is . . .*»)—formulate hypotheses about the meaning of the context. It is often stressed that one cannot find connotations except within a system or structure of connotations. This is all very well, but what if no one knows the structure?

At present, there is a rough, programmatically adequate working knowledge of important meaning relations in nearly all languages that have written literatures. As long as rough, low-level knowledge is sought, it is justifiable to rely heavily on existing vocabularies and grammars. If, however, finer shades of meaning and definite occurrences are of interest, let us say occurrences in a definite natural science text, then such a reliance involves working with prejudices that might completely destroy the analysis.

Among the things to be noted about vocabulary meanings of «unusual» words (for example, technical ones) is that they are often mere definiens formulations found in some technical text. Typically, the formulation is taken out of its context without consideration of the changed meaning it thereby will acquire. Or the formulation may be changed to avoid long phrases, cumbersome restricting clauses, and so on. Often, no occurrence analysis, or even limited choice analysis, has been made: one

VI. OCCURRENCE ANALYSIS

may say that questionnaires with one respondent, the lexicographer, have been used.

The more existing occurrence analyses there are, the less we may expect on the average to need to perform new ones. However, because languages are rich in designations, and rich in meaning-relevant contexts, progress must be slow. So far, narrow practical purposes have limited the quality of the work. Occurrence analysis of *sentences* is even slower to develop; very little has so far been done in that field.

B. Illustration of a Connotational Occurrence Analysis

VI.8. Delimitation of the Class of Occurrences to Be Analyzed

The following analysis has two aims: to illustrate distinctions, concepts, and theorems introduced in preceding chapters; and to describe by means of an example the kind of analysis that might be called «standard connotational occurrence analysis», since we search for complete connotations in the form of descriptive definitions.

The epithet «standard» is used to indicate that the steps recommended in the analysis are not the only possible ones, but delimit a kind of norm.

We have already referred several times to a booklet that we shall now use to exemplify connotational occurrence analysis, the booklet by D. Zaslavski called *La démocratie soviétique*, officially translated into French by J. Hepner and incorporated in the *Editions sociales* for 1946.¹³ The book covers certain aspects of the USSR, chiefly those under discussion when comparisons between the USSR and Western countries are undertaken.

Zaslavski is one of the editors of *Pravda* and has been prominent among the propagators of Communist ideology. His book is preferred to the works of Lenin or Stalin as an object of analysis because in the latter works, the term «democracy» occurs relatively seldom, whereas in Zaslavski's text of 107 small pages, it occurs 192 times. This high number of occurrences and the high relative frequency make it convenient for our purposes of illustrating the methods and difficulties of connotational occurrence analysis.

Our main objective will be to try to find out what, *if anything*, Zaslavski means by the words «democracy», «democratic» (etc.), by exploring his use of those words within the booklet. Evidence from other sources

will indirectly be taken into account, but no occurrences other than those in the booklet will be consulted.

The class of occurrences to be analyzed is the class of instances of the words

<i>démocraties</i>	<i>démocratiques</i>	<i>antidémocratiques</i>
<i>démocratie</i>	<i>démocratique</i>	<i>antidémocratique</i>

The text analyzed is that of Zaslavski, including its headings and the title on the book's title page. Any instance of «*démocratie*» (etc.) as a separate sequence of letters will be counted, regardless of the nearest letter sequence. Thus, in the expression «*la démocratie soviétique*», there is an occurrence. Whether the author might conceive «*démocratie soviétique*» as one indivisible designation is not taken into account in listing the occurrences. The possibility that «*démocratie*» is never used as a complete designation is, however, of importance to the conclusion. It might imply that «*démocratie*» is never intended as a concept designation. To express concepts, Zaslavski might use only complex designations such as «*démocratie soviétique*» and «*démocratie bourgeoise*».

The above indication of which occurrences our main hypotheses claim to cover is not sufficiently accurate to make it possible to class all text units into two separate classes, occurrences and nonoccurrences. There will be doubtful cases. The best method would be to offer a copy of Zaslavski's booklet as an appendix and to number every occurrence meant to be included.

In the absence of such an appendix, we offer a list (table 2) showing the pages on which occurrences are found. Clear-cut metaoccurrences are not numbered. Instances that can plausibly be interpreted as metaoccurrences, and plausibly as use occurrences, are numbered. The bulk of the numbered occurrences are clear-cut use occurrences.

VI.9. Implicate List

In the following pages I have not placed «democracy» in *guillemets*. The term recurs a great many times, and *guillemets* merely lengthen the text without introducing appreciably more clarity. I have therefore decided to write, «The designation «x» is used of a certain kind of democracy» instead of «The designation «x» is used of a certain kind of something that (by the author of the text analyzed) is designated by the term «democracy»».

VI. OCCURRENCE ANALYSIS

Table 2. Occurrence List of «Démocratie», etc., in Zaslavski

Occ. No.	Page	Occ. No.	Page	Occ. No.	Page	Occ. No.	Page.	Occ. No.	Page
1	5	51-	30	meta	36	meta	50	178	72
2	12	56	30	94	36	154	50	179	78
3	12	57-	31	95-	37	155	51	180	79
4	12	64	31	104	37	156	51	181	83
5	20	65	32	105-	38	157	51	182	89
6	22	66	32	113	38	158-	52	183	95
7-	23	67	33	114-	39	161	52	184	97
14	23	meta	33	121	39	162	53	185	99
15	24	68-	33	122-	40	163	53	186	101
16	24	72	33	127	40	164	53	187	103
17-	25	meta	33	128-	41	165	54	188-	106
24	25	73	33	133	41	166-	57	191	106
25-	26	74	33	134-	42	170	57	192	107
31	26	75-	34	141	42	171	58		
32-	27	82	34	142-	43	172	58		
40	27	83-	35	146	43	173	59		
41-	28	91	35	150	44	174	59		
44	28	92	36	151	47	175	69		
45-	29	93	36	152	48	176	69		
50	29	meta	36	153	48	177	69		

Note: A hyphen indicates all occurrence numbers falling between the number that precedes the hyphen and the number that follows.

Thus, even if we write «democracy» without guillemets, we do not ipso facto admit that the word belongs to our own vocabulary. We reproduce a designation used by others. What it designates is an open question for us as analysts; it belongs always to our metalanguage, never to our use language.

Occs. 2, 3, and 4 are found in a paragraph that may profitably be quoted in full:

Certains des nouveaux Etats surgis après le Traité de Versailles firent preuve de manque de stabilité et de solidité. Ils s'octroyèrent des Constitutions démocratiques [occ. 2] du dernier modèle, des Parlements, des suffrages universels et des programmes de vastes réformes sociales. Cependant, des discordes in-

testines firent bientôt leur apparition dans ces nouveaux pays, où des coups d'Etat amenèrent l'abandon des Constitutions démocratiques [occ. 3] et l'établissement des régimes les plus antidémocratiques [occ. 4] et même les plus réactionnaires. Telle est, par exemple, l'histoire de la jeune République polonaise, ainsi que d'autres pays comme la Yougoslavie, la Bulgarie, la Roumanie et la Hongrie. (Zaslavski 1946–47: 12)

Proposed implicates of special interest:

- i₁: Constitutions can be classed into democratic and nondemocratic ones.
- i₂: Democratic constitutions can be the latest models or older models.
- i₃: Regimes can be more or less antidemocratic.
- i₄: After the Treaty of Versailles, the countries Poland, Yugoslavia, Bulgaria, Romania, and Hungary adopted constitutions that were democratic; the democratic constitutions were of the latest model.
- i₅: Later, these countries abandoned the democratic constitutions and established the most antidemocratic regimes.

Occ. 5 reads, «Le régime soviétique est démocratique sous tous ses aspects, y compris son aspect économique» (ibid., p. 20).

Suggested implicates of special interest:

- i₆: Regimes may be classed into democratic and nondemocratic ones.
- i₇: The Soviet regime is democratic.
- i₈: Regimes may be democratic in various aspects, and can be democratic in some and nondemocratic in others.
- i₉: One of the aspects is the economic aspect.
- i₁₀: The Soviet regime is democratic in all aspects.

Occ. 6 comes after the sentence «La vieille société féodale ne voulut pas non plus reconnaître la société capitaliste et bourgeoise» (ibid., p. 22). The occurrence sentence reads, «La démocratie du peuple français au XVIII^e siècle était également une «énigme» pour le roi et la noblesse».

VI. OCCURRENCE ANALYSIS

Occurrence implicates of interest:

- i₁₁: There was a democracy of the French people in the eighteenth century.
i₁₂: That democracy was an «énigme» for the king and the noblemen.

Occs. 7–11 are all within one paragraph:

Les derniers temps, on entend les étrangers s'interroger beaucoup au sujet du système d'administration soviétique, au sujet des Soviets. On se demande ce qu'il représente. On dit que ce n'est pas de la démocratie [occ. 7]. On ne se contente pas de le dire, mais on le crie. On ne fait pas que le crier, on le hurle. C'est surtout cette partie de la presse opposée à toute démocratie [occ. 8] qui s'y évertue particulièrement. Elle devrait, semble-t-il, se réjouir que, de son point de vue, le pays soviétique ne constitue pas une démocratie [occ. 9]. Mais cette presse, qui est représentée en Amérique par Hearst et C^{ie} et en Angleterre par les conservateurs les plus réactionnaires est la plus effrénée à accuser le pays soviétique qui, voyez-vous, n'est pas une démocratie [occ. 10] et auquel il faudrait interdire l'accès au sein des puissances démocratiques [occ. 11].
(Zaslavski 1946–47: 23)

Suggested implicates of special interest:

- i₁₃: Outside the Soviet Union a part of the press is opposed to all democracy.
i₁₄: It is the part of the press that is especially eager to announce that the Soviet Union is not a democracy.
i₁₅: It is in the United States represented by Hearst & Co.
i₁₆: It is in England represented by the most reactionary of the conservatives.¹⁴

For the sake of brevity, implicates are in the following listed without direct quotation.

Occ. 17 (page 25):

- i₁₇: There is something new about Soviet democracy (compared with previous and other democracies).

Occ. 18 (page 25):

i₁₈: History did not know of a democracy such as Soviet democracy before the birth of the Soviet state.

Occs. 22–23 (page 25):

i₁₉: Countries can be classed as democratic and antidemocratic.

i₂₀: By the Second World War it was clear which countries were democratic and which were antidemocratic.

Occ. 24 (page 25):

i₂₁: The Second World War was a war of the democratic peoples against fascism.

Occ. 28 (page 26):

i₂₂: It is the hatred of democracy that is the common feature of the fascist states.

Occ. 29 (page 26):

i₂₃: Hitler and Mussolini set themselves the task of liquidating democracy in all its manifestations.

Occ. 32 (page 27):

i₂₄: During the war the menace of fascism cemented the union of all states practicing the various forms of democracy.

i₂₅: During the Second World War, there existed various forms of democracy, and these fought Mussolini's Italy and Hitler's Germany.

i₂₆: A state may practice democracy.

Occs. 33 and 34 (page 27):

VI. OCCURRENCE ANALYSIS

i₂₇: The war established a perfectly clear demarcation line between democracy and enemies of democracy. The line coincided with the line between the war camps.

Occ. 42 (Zaslavski 1946–47: 28):

i₂₈: The Atlantic Charter is a document that has the aim of affirming democratic principles in the whole world.

Occs. 48 and 49 (page 29):

i₂₉: If one could measure the strength of democratic feelings¹⁵ in degrees of hatred of fascism, the first place among democratic peoples would be occupied by the Soviet people.

Occ. 52 (page 30):

i₃₀: There is an American democracy.

i₃₁: It tolerates even now fascist propaganda in its press.

i₃₂: It is not incompatible with democracy to tolerate fascist propaganda in the press.

Occ. 53 (page 30):

i₃₃: There exists an English democracy.

i₃₄: It still upholds relations with fascist Spain.

Occ. 56 (page 30):

i₃₅: The friends of the Soviet Union outside that union constitute the democratic elements of their nations.

Occ. 62 (page 31):

i₃₆: It is to the Soviet Union that international democracy owes its salvation (consider the war events).

These are all implicates extracted from the sixty-six occurrences in the first chapter of Zaslavski's book. That chapter is mainly concerned with argumentation in favor of the conclusion that the Soviet Union is as much a democracy as other democracies, and even more so. In the next chapter, «The Power of the People», the main theme is a discussion of the essence of democracy, its definitional and most important nondefinitional characteristics.

The short second chapter (eight pages) contains occs. 67–133, and among them, some definitoid statements. The first pages of the chapter are of great interest for the theory and practice of elementary analysis. They are also well suited for illustrating the difficulties of occurrence analysis and the necessity for making distinctions that might on first sight seem pedantic and unnecessary. The discussion of those points (see section 17) is intended also to illustrate interpretational oscillations (chapter 2, section 13).

Zaslavski's second chapter opens thus:

Qu'est-ce qu'une démocratie [occ. 67]? Le mot répond, semble-t-il, par lui-même. Le mot démocratie [metaocc.] est d'origine grecque. *Demos* signifie peuple et *kratos* pouvoir. Démocratie [occ. 68] est le pouvoir du peuple. La démocratie [occ. 69] est l'antithèse de l'aristocratie, du pouvoir des nobles. La démocratie [occ. 70] est aussi l'antithèse de la ploutocratie, du pouvoir des riches. Les grands créateurs de la démocratie [occ. 71] américaine établirent une forme plus étendue de la démocratie [occ. 72] en la définissant comme le pouvoir du peuple, pour le peuple, par le peuple. (Zaslavski 1946–47: 33)

The following implicates are suggested:

Occ. 68 (page 33):

i₃₇: Democracy is the power of the people.

Occ. 72 (page 33):

i₃₈: The great creators of the American democracy defined democracy as the power of the people, for the people, by the people.

Occ. 79 appears in the following passage:

La démocratie [occ. 79] ne fut pas toujours de même nature au cours de l'histoire de l'humanité, car ses formes se modifièrent. A une époque déterminée, le

VI. OCCURRENCE ANALYSIS

mot «peuple» signifiait une chose, alors qu'il changeait de sens à une autre époque. (Zaslavski 1946–47: 34)

Suggested implicates of occ. 79:

- i₃₉: Democracy has not always been of the same nature throughout the history of humanity.
- i₄₀: Its forms have changed.

For the rest of the chapter, it suffices to state some implicates:

Occ. 80 (page 34):

- i₄₁: In countries with a majority and a minority, democracy is the power of the majority of the people.

Occ. 81 (page 34):

- i₄₂: Because workers make up the majority in such countries, power should belong to the workers in democratic countries.

Occ. 84 (page 35):

- i₄₃: A state where the power is in the hands of a minority is no true democracy.

Occ. 85 (page 35):

- i₄₄: It is no more than a partial democracy.

Occ. 86 (page 35):

- i₄₅: England is a bourgeois democracy.

Occ. 87 (page 35):

- i₄₆: Bourgeois democracy is a limited, imperfect form of democracy.

Occ. 95 (page 37):

i₄₇: History does not know of an eternal and unchangeable democracy.

Occ. 96 (page 37):

i₄₈: Democracy develops as do all other forms of society.

Occs. 97 and 98 (page 37):

i₄₉: Soviet democracy does not resemble the old form of democracy.

Occs. 101 and 102 (page 37):

i₅₀: Democracy in a state in which there exist several classes with opposing interests differs radically from democracy in a state that does not know of class struggle.

Occs. 103 and 104 (page 37):

i₅₁: Not the absence of capitalists and landlords, but their presence hinders numerous states from developing into authentic democracies.

Occs. 107 and 108 (page 38):

i₅₂: Fascism, which is a sworn enemy of democracy, has declared war on all democracies, old as well as new.

Occs. 110–112 (page 38):

i₅₃: Soviet democracy and bourgeois democracy have a common origin.

Occs. 114 and 115 (page 39):

VI. OCCURRENCE ANALYSIS

i₅₄: Without bourgeois democracy, there would have been no Soviet democracy.

Occs. 119 and 120 (Zaslavski 1946–47: 39):

i₅₅: Soviet democracy is the historic rejection of bourgeois democracy.

Occs. 121 (page 39):

i₅₆: Germany is crushed, but the menace to democracy is still present.

Occs. 122 and 123 (page 40):

i₅₇: United action is necessary to the development of new forms of democracy, such as U.N.O.

i₅₈: International democracy is not possible without the various democratic states continuing to stand together.

Occs. 126 and 127 (page 40):

i₅₉: Reaction is the common enemy of both the new Soviet democracy and the old bourgeois democracies.

The rest of the book is devoted to the subjects mentioned in the headings of the chapters—political parties, elections, and the press—and gives arguments in favor of the Soviet Union being a democracy, and being an authentic democracy, whereas the bourgeois democracies are not. Here are some implicates of importance:

Occs. 138 and 139 (page 42):

i₆₀: If plurality of parties were a criterion of democracy, the existence of parties would have been mentioned in democratic constitutions.

Occ. 141 (page 42):

- i₆₁: If the number of political parties ought to be an index of the democratic character of a country, priority (*primauté*) would have to be given to the Austro-Hungarian monarchy.

Occ. 156 (page 51):

- i₆₂: The existence in the Soviet Union of only one political party recognized by the constitution is a new phenomenon characteristic of a democracy of a new type.

In connection with these occurrences, Zaslavski states the doctrine that political parties result from class antagonism. Absence of such antagonisms results in absence of plurality of parties.

Occ. 158 (page 52):

- i₆₃: Soviet democracy is therefore the power of the people, for the people, and by the people.

This conclusion is stated after the following section: «Le pouvoir y appartient au peuple et au peuple seul qui est le maître de toutes les richesses de la terre. C'est dans l'intérêt exclusif du peuple que travaillent l'industrie et l'agriculture soviétiques. Seuls, les représentants des ouvriers, des paysans et des intellectuels, les élus du peuple, exercent le pouvoir. Les intellectuels soviétiques constituent une partie intégrante de la classe ouvrière et paysanne.» (Zaslavski 1946–47: p. 52)

Occ. 163 (page 53):

- i₆₄: The new feature of the Soviet democracy is that it is an authentic democracy.

Occs. 175 and 176 (page 69):

- i₆₅: The essential condition of an authentic democracy applied to elections is that it is made by the entire populace.
- i₆₆: The elections to the Supreme Soviet satisfy this condition and are the most democratic in existence.

VI. OCCURRENCE ANALYSIS

Occ. 192 (Zaslavski 1946–47: 107):

- i₆₇: Soviet democracy is the profoundest and most extensive democracy in the world.
- i₆₈: The most extensive democracy in the world is not only the power of the majority; it is the power of the people as a whole.

VI.10. Inferences in Relation to Occurrences 1–66

The implicates are sentences that are assumed to have meaning for the author of the texts analyzed. It is assumed that he would not only understand them, but also approve of them as tenable assertions about his own verbal habits or rules.

The next step in occurrence analysis is the formulation of sentences in the vocabulary of the analyst and his public—sentences that to him and his public express the same as the implicates are assumed to express for the author analyzed.

If an expression, T_0 , used in an implicate, makes the analyst wonder whether the author has by T_0 intended T_1 or T_2 (T_1 and T_2 being expressions in the vocabulary of the analyst), the aim at this new step of occurrence analysis will be to find out whether T_1 or T_2 is the more plausible interpretation of T_0 . If, on the other hand, the analyst is confident that the author did not have sufficient definiteness of intention to intend either T_1 or T_2 , then neither T_1 nor T_2 can be used in the analyst's version of the implicate. The criteria of definiteness of intention are so difficult to apply that in the following we do not take into consideration the possibility that the analyst's versions of the implicates are in part based on transintentional precisizations.

In the following, some reformulations of the implicates are listed. They are inferred on the basis of more or less uncertain hypotheses (auxiliary hypotheses) that cannot all be made explicit because of their multiplicity and their complicated content.

In the following, we have not found it practicable to report on interpretations of every occurrence sentence or implicate. Those not mentioned

in what follows are assumed to have been interpreted by the analyst, even if no report is given. Such assumptions are necessary in order to justify the concluding steps of the analysis.

Occurrence 1: «The Soviet Democracy»

Occ. 1 is in the book's title, *La démocratie soviétique*. Tentative interpretations of the title are:

- T₀: Soviet democracy.
- T₁: The particular democracy with the name «USSR».
- T₂: Democracy of the kind realized in the USSR.
- T₃: Democracy-by-Soviets («Soviets» used as the name for a certain kind of group to be discussed).

T₃ is excluded without further discussion because of the secondary importance attached to discussion of Soviet groups within the text.

Tentatively proposed inferences based on the above interpretations are:

There is a democracy.	T ₁ – inference
The Soviet Union is a democracy.	T ₁ – inference
There is a Soviet democracy.	T ₂ – inference
The USSR is a Soviet democracy.	T ₂ – inference

Let us at once admit that these interpretations and inferences are suggested by previous reading of Soviet literature and by preconceptions about Zaslavski. Thus, I presume he is a defender of all that he calls «*soviétique*». Without such preconceptions, a greater number of directions of precization would have to be considered. The hypotheses that Zaslavski has a consistent positive evaluation of all that is called «*soviétique*», and a predominantly positive evaluation of all that is called «*démocratique*», are used as auxiliary hypotheses in need of confirmation. For further discussion of this point, see pages 351–52.

If a fourth interpretation, «the so-called Soviet democracy» (T₄), were taken seriously, there would be inferences such as:

VI. OCCURRENCE ANALYSIS

Some call the Soviet Union a «democracy».

Some call something «a Soviet democracy», etc.

Using our working hypotheses about positive evaluation and a hypothesis about negative evaluation expressed by «so-called democracy», we leave out these inference possibilities.

The designation «*démocratie soviétique*» is perhaps used as a *terminus technicus* for a kind of democracy, a subclass of democracies. The interpretation of «*démocratie soviétique*» in this direction implies the conceivability of Soviet-democracies besides the USSR (for example, that the USSR is taken as an example of something).

There are sentences on (Zaslavski 1946–47) pages 34ff. on types (forms) of democracy that support such an interpretation. The comparison of «*démocratie soviétique*» suggests the possibility of using the term as a class name. Zaslavski names several bourgeois democracies and uses the term in the plural (for example, on page 35), so the class-name nature of that designation is fairly certain.

There is, however, no single occurrence of «*démocratie soviétique*» that cannot plausibly be interpreted in accordance with T_1 , «the particular democracy with the name «USSR»», whereas some occurrences are not easily interpreted in accordance with T_2 . To take an example: «Mais ce ne sont évidemment pas ces documents [la Charte de l'Atlantique, etc.] qui comptent le plus. Ce qui importe davantage, ce sont les actes historiques que ces documents reflètent et qui en font la valeur. Ces actes sont les sacrifices sans exemple de la démocratie soviétique consentis pour le salut de la culture mondiale et de la démocratie internationale» (ibid., p. 28).

In view of the somewhat heavier evidence favoring T_1 over T_2 , the former is selected as the main interpretation.¹⁶ There is, however, no clear-cut reason to believe that Zaslavski always intends to convey T_1 rather than T_2 , or vice versa. At some places the one may be intended; at other places, the other. Moreover, sometimes there may not have been sufficient depth of intention to permit us to distinguish discrimination possibilities of the kind required.

From the inference «The Soviet Union is a democracy», it may be deduced that «There is nothing that truly can be affirmed about the Soviet Union (up to 1946) that is incompatible with its being a democracy».

It is of basic importance to this analysis that the criterion concerning

what «truly can be affirmed» is *agreement with Zaslavski's views at the moment he produced the text*. Roughly, we may say that as long as we are concerned with implicates from occurrence sentences, our subject matter is the *language of Zaslavski*. Our inferences mainly concern Zaslavski's *opinions* and our conclusions in the form of descriptive definitions concern his *language*.

If occ. 1 were followed by details on the Soviet Union, then we would collect details on characteristics compatible with democracy as conceived by Zaslavski. In the course of the book, Zaslavski asserts quite a number of propositions about the Soviet Union, and these will be collected in relation to occ. 1, to enable us to infer as much as possible from that occurrence. When we consider what can be inferred from the inference «The Soviet Union is a democracy», not only are *propositions* involving what is «*soviétique*» important, but also clarifications and definitoid statements on «the Soviet Union» and «*soviétique*». Thus, on page 7, it is said that «L'Union Soviétique --- créa --- une nouvelle forme de gouvernement, à savoir les Soviets» (ibid.). This saying suggests some relation between being the Soviet Union and being a form of government, which in turn suggests an intimate relation between being a form of government and being a democracy.

Occurrences 2–4: Democratic and Antidemocratic Regimes

We now move on to a discussion of implicates i_1 – i_5 (for full text, see pages 333–34).

The «more or less» of i_3 («Regimes can be more or less antidemocratic») is of interest because it suggests a use of «antidemocratic» and «democratic» for a graduated characteristic, a characteristic being present in varying degrees. The existence of such a gradation would make it of subordinate interest to find a sharp line of delimitation between democratic and antidemocratic, because the gradation would probably be caused by corresponding gradations of conceptual characteristics.

As a matter of fact, theorists usually abandon the dichotomies democratic/nondemocratic and democratic/antidemocratic in their detailed discussions of what is meant by «democracy». Most definitoid statements do not go into details, however, and they are formulated in terms of the dichotomy. Definitions based on «more (less) democratic than» rather than «democratic» or «democracy» are comparatively rare. Instances are found,

VI. OCCURRENCE ANALYSIS

for example, in Alf Ross (1946), J. Jørgensen, Naess (1942), Salvador de Madariaga (1958), and Harold D. Lasswell (1948).

Some plausible, legally oriented interpretations of «constitution» as used in implicate i_5 provide useful hints about what might be meant by constitutions being democratic. This leads us to a survey of some constitutions of the past and Zaslavski's opinion of those constitutions. These opinions can probably be somewhat more easily inferred and described than his view on the *regimes* called «antidemocratic». Descriptions of characteristics of a constitution may be expected to vary less than descriptions of regimes when by «regimes» is meant, for example, particular historical governments as they operate, rather than forms of government. Thus, we would guess that if we cannot find direct statements by Zaslavski about the regimes referred to, we may expect to obtain more reliable hypotheses about his use of the term «democratic» by following up the path of i_4 rather than i_5 .

If a broad occurrence analysis including information on denotata of 'democracy' were aimed at, i_4 would in itself constitute a result of analysis. However, the information on Zaslavski's opinion of Yugoslavia's relation to democracy is only of value as a possible basis for hypotheses about what is meant by «democratic».

From occs. 3 and 4 we might tentatively infer: as long as the constitution of a state is democratic, antidemocratic regimes cannot be established.

Finally, we may say that occs. 2–4 indirectly provide us with a great mass of information by their references to historical happenings and documents.

Occurrence 5

After occurrence sentence 5 (for text, see page 335), Zaslavski makes statements that probably are meant to document his assertion that the Soviet regime is democratic in the economic aspect. About the millions of workers, engineers, and so forth, he says, «Il est indispensable qu'ils sachent ce qui se passe dans l'entreprise en «état d'émulation»; ---». Just before the occurrence sentence, we read: «Le collectivisme qui y est appliqué signifie que les plans de nouvelles entreprises, les nouvelles méthodes de travail sont examinés et discutés non pas dans le bureau d'un entrepreneur, mais dans les réunions publiques où la presse a accès. Les inventions des stak-

hanovistes deviennent l'apanage du peuple entier. Nous ignorons les «secrets de production», sous la forme où ils existent dans l'industrie capitaliste, où le propriétaire d'une entreprise est aussi le propriétaire du secret.»

Maybe the democraticity of the economic aspect according to Zaslavski (1946–47: 20, 21) means, roughly speaking, that every man or woman engaged in economic activities is allowed to inspect and discuss how these activities are led, that he or she has access to all information on all industrial processes and related matters, except military secrets. In recent discussions, the term «industrial democracy» is sometimes used in meanings closely related to this, whereas «democratic in the economic sense» is taken to refer to equality of opportunity, income, salaries, and so on. There is no indication that the term is thus used at occ. 5.

If the above rough indication of the sense in which Zaslavski uses «economic aspect» is tenable, it would confirm the assumption that the sentence following the occurrence sentence is intended to elaborate what is implied in the phrase «economic aspect». That sentence reads, «Dans aucun pays du monde, l'observation de la vie n'est aussi libre que dans le pays soviétique».

The democraticity of the economic aspect might then perhaps be said to consist in the possibility of every citizen being able to inspect, discuss (and criticize) every feature of economic life.

This vaguely formulated hypothesis about Zaslavski's usage is neither confirmed nor disconfirmed strongly by later occurrences. Unhappily, the expression «democratic in the economic aspect» does not again appear in the text.

Other hypotheses may work just, or nearly, as well—for example, the hypothesis that democraticity in the economic sphere consists in all industrial engineers having access to all inventions and to all information about industrial plants. Such conditions might be contrasted with those prevailing in countries with patent laws.

Both hypotheses may prove to be misleading and the result of too much stress on the immediate context.

The heading of chapter 1 reads, «L'État soviétique n'est ni une utopie, ni une expérience, ni une énigme». Occ. 5 is part of a trend of argumentation in that chapter against the Soviet Union's being an enigma. Therefore, Zaslavski stresses that the economic life of the Soviet Union is open to in-

VI. OCCURRENCE ANALYSIS

spection by foreigners through publications, reports, and so on. This broader context of occ. 5 would thus in part explain why the sentence elaborating the democraticity of the economic aspect is limited to the topic of openness to inspection and discussion. If there were a chapter on distribution of economic goods, one might find occurrences such as to make a third hypothesis more probable than the first two.

A verdict that «hypothesis 1 and not hypothesis 2 about occ. 5 is strongly confirmed (or weakened) by analysis of further occurrences» presupposes that each hypothesis's intended field of application is extended beyond occ. 5. Such an extension is rather inevitable if we hope to collect a satisfactory amount of evidence. As a matter of fact, very little evidence for one or the other can be gathered from analysis of Zaslavski's text. On the other hand, there is even less evidence of «democratic in the economic aspect» being used to connote 'equality of opportunity to work and earn money', or 'equality of income'. Such a situation is very common in connotational occurrence analysis of a single, only moderately long text. There is insufficient material to confirm or disconfirm strongly any hypothesis of interest. One way out of the difficulty is to create a supplementary text of high relevance. This can be done by questionnaire methods. The questions can be constructed in such a way that answers are apt to throw light on just those hypotheses that have been tentatively formulated on the basis of occurrence analysis. Generally, however, it is more convenient to use questionnaires first, then go into occurrence analysis, or to mix the two methods during all stages of the investigation.

Occurrences 6–11: Various Democracies

For the identification of the phenomenon that Zaslavski calls «the eighteenth-century French democracy», the sentences that follow occurrence sentence 6 (see implicates i_{11} and i_{12} , pages 335–36) are important: «Ils ne *pouvaient* pas comprendre cette énigme, car ils ne *voulaient* point la comprendre. Et ils ne le voulaient pas parce qu'ils *craignaient* de comprendre. La politique des Louis avant la grande Révolution bourgeoise en France était une politique d'autruche qui cache sa tête sous son aile.» The usefulness of i_{11} is somewhat reduced because Zaslavski does not say much more about the old French system of democracy.

Occs. 7–11 (see implicates i_{13} – i_{16} , page 336), with the exception of occ. 8, are doubtful because one cannot be sure that Zaslavski intends to use the word in his own sense. He may intend to quote the Westerners in their own terminology. I suppose, however, that Zaslavski wishes to be understood to state that the part of the press under consideration denies that the Soviet Union is a democracy in the sense that «democracy» has for the readers of his book, and that sense I suppose he would consider identical with his own.¹⁷

Zaslavski seems to be of the opinion that some people fear the consequences of admitting that the USSR is a democracy. He further thinks that they cannot, on the other hand, classify it as an aristocracy, plutocracy, or other such form of government. Therefore, the USSR must be an enigma in their eyes (cf. Zaslavski 1946–47: 22ff.). If those people, by «democracy», meant something very different from what Zaslavski means, then Zaslavski would not be sure why they should be frightened. These and other reflections support the status of occs. 7–11 as genuine occurrences, that is, occurrences of Zaslavski's own usage.

Occurrences 12–66

Occurrence sentences 12–66 are among the most important for our analysis, but only a few of them will be discussed in what follows. More adequate exposition would require too much space.

From occ. 14 and its context (*ibid.*, p. 23), we infer:

inf_2 : A democracy is neither an aristocracy nor a plutocracy.

Although important, this inference is highly uncertain; therefore, it was not listed among the implicates. The inference «Soviet democracy is neither an aristocracy nor a plutocracy» is much less uncertain, but also less important.

Implicate 18 (page 337) suggests, but very weakly, that «democracy» here is used about a state form. It supports the claim that «Soviet democracy» in occurrence sentence 17 is used as a class name. If the designation were, for example, a name for «the regime in the USSR», occ. 18 would be rather trivial: «history did not know of the regime in the USSR before the

VI. OCCURRENCE ANALYSIS

birth of the Soviet state». Implicates 21 and 22 (page 337) are of importance because occ. 28 is followed by a description of what fascism is the negation of. From occs. 24 and 28 and the description, we derive:

inf₃: The democratic peoples have fought the negation of the following phenomena:
sovereignty of the people,
their independence and freedom,
the equality of citizens,
the civil liberties,
the democratic culture,
philosophy,
science,
theory and practice of parliamentarism.

Implicate 27 (page 338) and some of the foregoing implicates are of special interest because by means of them we can construct a list of denotata of 'democracies' for the time interval between 1939 and 1945 or a large part of it. In i_{27} , «line between democracy and enemies of democracy» may be interpreted in the direction of «line such that *all* democracies were on one side, and only enemies of democracies were on the other side». If this interpretation holds, the list of the Allied countries during the Second World War is a complete list of denotata. The class of common and specific properties (as conceived by Zaslavski) of these countries contains all the conceptual characteristics of 'democracy'. A complete list of denotata valid for a certain time interval is one of the most valuable assets in occurrence analysis, but, alas, several difficulties have to be surmounted to make adequate use of the material.

The conjunction of the common and specific properties of a class of things implies the conjunction of conceptual characteristics of the concept that has that class of things as its complete class of denotata. But if the class is very rich, and the conceptual characteristics poor, there will be a pronounced uncertainty in the inferences leading from the conjunction of common and specific characteristics to the conjunction of conceptual characteristics. To give an illustration: if some A pearls or parts of them make up all B pearls, and this is all we know about B pearls, and if there are many

A pearls and few B pearls, there is little chance that we can pick out just those A pearls that also are B pearls. If the list of Allied countries is conceived as a *complete* list of denotata of 'democracy', then the absence of Sweden and Switzerland from the list makes it complicated to find common and specific characteristics for the listed countries.

Let us, on the other hand, interpret «line between democracy and enemies of democracy» in the direction of «line such that on one side all were democracies, and on the other side all were enemies of democracies». On the basis of this interpretation, Zaslavski may not be willing to take the list of Allied countries as a *complete* list of denotata. There are still difficulties, however. Finland is not on the Allied list, but on the list of enemies of democracy. We shall, therefore, have to find common and specific characteristics of Denmark, Greece, and Poland in contrast to Finland such that among the common characteristics of the three countries, all the conceptual characteristics of 'democracy' are to be found.

One may here legitimately ask, Do we not by the implicates and their interpretation transcend the definiteness of intention of the sender? It may well be that the sender does not intend to make a strict and accurate line between Allies and their foes. He may not have thought about particular countries at all. In that case we have no basis for making a list of denotata. There are, however, in the text many symptoms that such a line is intended:

Le danger cimentait l'union contre le fascisme de tous les Etats pratiquant les diverses formes de démocratie [occ. 32]. La guerre établit une ligne de démarcation absolument nette entre les deux camps. Ce qui était d'un côté de cette ligne appartenait à la démocratie [occ. 33]. Tout ce qui était de l'autre aux ennemis de la démocratie [occ. 34], au fascisme. Il apparut clairement que la co-existence de ces deux systèmes était impossible. Il devint tout aussi clair qu'il ne saurait y avoir de formes intermédiaires ou transitoires. Démocratie [occ. 35] ou fascisme, tel était le problème de vie ou de mort posé par l'histoire.

(Zaslavski 1946–47: 27)

I suspect, however, that it is untenable to attribute the following opinion to Zaslavski: «Denmark, Greece, and Poland in 1939–1945 (including the time just before declarations of war), in contrast to Finland, manifest all conceptual characteristics of democracies».

VI. OCCURRENCE ANALYSIS

The question is then, How should we modify or interpret the occurrence sentences and our implicates to avoid the consequence that such an opinion can be inferred from them?

One possibility is to interpret «democratic people» and «war» in occs. 24, 33, and 34 and certain other designations of other occurrence sentences in such a way that (a) «war» and «fight» refer also to conflicts that do not have the status of war in the sense of international law and (b) those fighting need not be «peoples» in the sense of «nations» but can also be factions within nations. By making interpretations in this direction, we remove the line of demarcation between democrats and fascists during the world war that can be inferred from the list of belligerent nations.

Or, it is possible that Zaslavski has reasoned somewhat as follows: «The readers of this booklet have, on the whole, rather confused ideas about which countries were engaged in the fight. They will not spend much time reading my sentence and will apply my indications only to those countries mentioned in the text. They will either not think of Finland, or only remember the severe criticism it suffered in the press of the Allied powers. Thus, on the whole, my readers will get a correct picture of the situation even on a somewhat doubtful basis.»

Such a possibility involves the hypothesis that in writing the booklet, Zaslavski occasionally abstains more or less consciously from interpreting his sentences in a fairly precise way because his main task is to convey something to readers who interpret with very low definiteness of intention and on the basis of very meager information.

We do not need to decide which possibility is most plausible. The present analysis is an illustration of occurrence analysis, and the present dilemma shows some of the kinds of hypotheses that must constantly be evaluated during the work with inference classes.

VI.11. Inferences from Zaslavski's Definitoid Statements on Democracy

Implicate 37 (see page 339) may be interpreted in various directions. One involves the type of sentence intended. We may say that it concerns precisizations of «is». We venture to suggest that the following, among others, are based on plausible interpretations of Zaslavski:

- T₁(i₃₇): The word «democracy» signifies, as used by competent persons, 'the power of the people'.
T₂(i₃₇): The essential characteristic of a democracy is the power of the people.
T₃(i₃₇): The word «democracy», as used correctly, has the connotation 'the power of the people'.
T₄(i₃₇): 'The power of the people' is a necessary and a sufficient criterion of democracy and the one I [Zaslavski] use.

What «correctly» in T₃(i₃₇) means, how the criteria of correctness are applied, and so on, are here left unprecized.

From occs. 69 and 70 of the quoted passage (page 339), we extract the following inference:

- inf₄: If power is in the hands of the noble or the rich, there can be no democracy.

To understand this inference as well as the definitoid statements, it is important to obtain information about how Zaslavski (1946–47) uses «power» and «people». He says on page 33 that «the words people and power have not always been used *à bon escient*», and discusses their use:

Le mot démocratie [metaocc.] est d'origine grecque et la forme démocratique [occ. 73] d'administration d'Etat naquit dans l'ancienne Grèce. La République d'Athènes fut une démocratie [occ. 74]. C'est le peuple qui y exerçait le pouvoir. Il avait coutume de se réunir sur une place publique et ses représentants prenaient des décisions sur l'administration de l'Etat par voie de consultation et de votes.

Toutefois, ce n'est pas la population entière qui était considérée comme *démós* et prenait des décisions sur les questions d'administration. Les esclaves, fort nombreux à Athènes, n'étaient pas considérés comme *démós* et ne faisaient pas partie du peuple. Ils ne jouissaient ni de droits civils, ni de droits civiques, bien qu'ils fussent les artisans de la richesse de la démocratie [occ. 75] athénienne. Cela signifie que la première démocratie [occ. 76] était une démocratie [occ. 77] esclavagiste. Elle n'était pas une démocratie [occ. 78] dans notre sens du mot. Le pouvoir appartenait non pas au peuple, mais à une partie du peuple.

Les temps anciens ne sont pas les seuls à avoir connu une telle situation.

(Zaslavski 1946–47: 33)

VI. OCCURRENCE ANALYSIS

The first section of the quoted passage strongly suggests that «democracy» in occs. 73 and 74 is by Zaslavski intended to be used in the sense he attaches to the word himself. Similarly, the first section suggests that «people» and «power»—important definiens expressions—are intended to be used in the sense Zaslavski would use them himself. Accordingly, we extract:

- inf₅: The democratic form of state administration was born in ancient Greece.
- inf₆: The Athenian Republic was a democracy.
- inf₇: It was the people who exercised the power in the Athenian Republic.
- inf₈: It is a sufficient condition for calling a state administration democratic that the people of the state have the custom of assembling at a public place and their representatives make decisions on the administration of the state by the way of consultation and votes.
- inf₉: It is a sufficient condition for calling a state a democracy that the people exercise the power.
- inf₁₀: The people exercise the power, if they have the custom of assembling (etc.).
- inf₁₁: It was a part of the populace, the free citizens, who exercised the power in the Athenian Republic.

In the second section of the quotation, however, it seems as if Zaslavski intends to use «the people» as synonymous with «the entire population».

Using this precization of «people», we may formulate important new precizations of i₃₇:

- T₅(i₃₇): Democracy is the power of the entire population, etc.

Making the last sentences of the second section the basis of our interpretation of Zaslavski, we conclude that inferences 5–10 are misleading. If «democracy», «people», and «power» are taken in the sense intended by Zaslavski—for example, «the people» taken as synonymous with «the entire population»—then he would reject inf₅–inf₁₀ as false assertions. He even *explicitly* denies inf₆.

The inferences might be retained but precized, for example, as follows:

T₁ (inf₆): The Athenian Republic was a «democracy» in at least one sense of the word.

Our contention is that, having read the first *and* second sections of the quoted text, and having read them in close connection with the opening sentences of the chapter, we would do the right thing to reject «occurrence» 74 («The Athenian Republic was a democracy») as an example of «democracy» being *used by Zaslavski*. Similarly, we reject the sentence «It is the people who there exercised the power» as evidence of Zaslavski's use of «people» and «power». All the sentences of the first section of the quotation (except the first sentence) we take as a sample of indirect speech by which Zaslavski characterizes a usage that is *not* as it should be (not «*employés à bon escient*»).

This conclusion I consider very shaky, but better confirmed than the rival view described on page 356.

In conformity with this conclusion, occs. 75–77 should also be rejected as examples of the usage of Zaslavski. One inference may be noted, however, based on occs. 76–78:

inf₁₂: The first so-called democracy, the Athenian Republic, was a slave democracy, not a democracy in our sense of the word.

The reader of inf₁₂ is expected to read it as if it were formulated by Zaslavski, which implies the use of T₅(i₃₇).

Is it fairly certain that Zaslavski intends to use «democracy» in his sense in i₃₉? In view of the last sentence of the quotation and related to the previous quotation, I am inclined to answer no. What Zaslavski means by «democracy» in occ. 79 may be «so-called democracy», «anything called democracy at least within one epoch». If so, then we get the so-called «forms of democracy» as descriptions of the classes of things *at least once called «democracy»*. Accordingly, i₃₉ should be changed to something like:

T₁(i₃₉): What has been called «democracy» was not always of the same nature throughout the history of humanity.

In accordance with this, we interpret the implicates on pages 340–41ff.:
Occ. 80:

VI. OCCURRENCE ANALYSIS

inf₁₃: In countries with a majority and a minority, what is called «democracy» is the power of the majority of the people.

Occ. 81:

inf₁₄: Because as workers make up the majority in such countries, power should belong to the workers in so-called «democratic countries».

Occ. 83 and context:

inf₁₅: In bourgeois democracies the real power remains in the hands of a capitalist minority—even when the workers have the political power in a parliament.

Occ. 84:

inf₁₆: A state in which the power is in the hands of a minority is no democracy (in the sense of Zaslavski).

Occ. 85:

inf₁₇: It is no more than a partial democracy (which is not a democracy in the sense of Zaslavski).

Occ. 87:

inf₁₈: Democracy in the sense of Zaslavski is true democracy.

Occ. 88:

inf₁₉: It is also democracy in the strict sense of the word.

Occ. 95:

inf₂₀: History does not know of anything eternal and unchangeable called «democracy».

Occ. 96:

inf₂₁: What is called «democracy» develops as do all other forms of society.

Occs. 97 and 98:

inf₂₂: Soviet democracy does not resemble the old form of so-called «democracy».

Occs. 101 and 102:

inf₂₃: So-called «democracy», in a state in which there exist several classes with opposing interests, differs radically from democracy in a state that does not know of class struggle.

Occs. 107 and 108:

inf₂₄: Fascism, which is the sworn enemy of so-called «democracy», has declared war on all that has been called «democracy», old as well as new.

Occs. 122 and 123:

inf₂₅: United action is necessary for the development of new forms of so-called «democracy», such as U.N.O.

Occs. 124 and 125:

inf₂₆: International democracy is not possible without the various so-called «democratic» states standing together.

VI.12. Other Inferences

This investigation of Zaslavski's *La démocratie soviétique* is made to *illustrate* the somewhat abstract theoretical structure of occurrence analysis. It would

VI. OCCURRENCE ANALYSIS

take too much space to construct detailed inference lists. We shall therefore limit ourselves to mentioning only a few additional inferences:

- inf₂₇: The USSR is a state of workers and peasants, and because socialist economy is in the interest of both, no antagonism of class can develop, and therefore no multiplicity of political parties (Zaslavski 1946–47: 51).
- inf₂₈: The Communist party in the Soviet democracy is a power that guides and directs (page 67).

From implicates i_{38} and i_{63} (occs. 72 and 158), we infer:

- inf₂₉: Democracy is the power of the people, by the people, for the people (page 67).

Occ. 158 (i_{63}) furnishes additional evidence that Zaslavski accepts the definiens formula so often found among Western ideologists and quoted by him in chapter 2.

In the Soviet Union there is universal, direct, equal, and secret suffrage, according to Zaslavski (page 55). This declaration is useful for constructing hypotheses about the requirements that Zaslavski would make definitional for authentic democracies. As regards elections, Zaslavski sets forth requirements (necessary conditions of authentic democracy) explicitly.

From occ. 166 and its context (page 57), we infer:

- inf₃₀: No democracy exists where election machines of parties organize and prepare elections, because usually to prepare an action means to realize it.
- inf₃₁: No democracy exists where only a small minority has access to the preparation of elections.

From occ. 172 and its context (page 58), we infer:

- inf₃₂: No true democracy exists where the people not belonging to a political party—that is, the vast majority of the people in any country—cannot choose their candidates.

VI.13. Narrow Concepts of 'Authentic Democracy' Versus Broad Concepts of 'Democracy, Authentic or Nonauthentic'

We have quoted only from Zaslavski's *La démocratie soviétique*, and the occurrence inferences are all from that book. This does not mean that when we now construct hypotheses about Zaslavski's usage, we use *only* the sentences of that book as evidence. Such a procedure would be interesting and valuable as an illustration of the exceedingly meager results that emerge from strict adherence to the evidence of a text taken in isolation. In practice, however, such adherence would prevent us from acquiring material necessary to establish descriptive definitions of usage.

It is our intention to let the hypotheses on usage have as a *primary* observational field the text of Zaslavski. We shall feel particularly responsible for mistakes in evaluation of evidence from that source. In reality, however, our choice of hypotheses is determined to a large extent, and in a way that is difficult to test, by previous reading, especially of literature on democracy by Soviet and other authors.

In the foregoing we have used the expression «hypotheses about Zaslavski's usage» to designate what we are trying to find. The expression should be interpreted as a deprecization of «synonymity hypotheses giving a precization, or many precizations, of «democracy» such that the readers of the hypotheses will in their interpretation come as near as possible to the interpretation or interpretations that Zaslavski himself applies to the occurrences of «democracy» in the text *La démocratie soviétique*. Zaslavski's intended interpretation at the moment¹⁸ of the production of the text is the objective of our analysis.

A survey of the inferences suggests that it is unfruitful to *start* our discussion of descriptive definitions covering Zaslavski's use of «democracy» by references to the hypothesis suggested on pages 357ff. that very few or no occurrences are subsumable under the definitions Zaslavski himself gives of the term, and that the rest are not occurrences of the use of «democracy» but occurrences in the metalanguage.

Two main directions of precization can be indicated by the interpretations T_1 and T_2 :

T_0 : Democracy.

VI. OCCURRENCE ANALYSIS

- T₁: Authentic democracy.
T₂: Democracy, authentic or¹⁹ nonauthentic.

The expression «authentic democracy» (T₁) is one that Zaslavski uses himself; the expression T₂ is not used by him. T₂ gives concepts of wider connotation than T₁. T₂ has the form of a disjunction of two characters, «a v b», in which one is a concept expressed by T₁.

Our first hypothesis will be:

At least once, Zaslavski uses «democracy» to express something nearer to a plausible interpretation of «authentic democracy» than to a plausible interpretation of «democracy, authentic or nonauthentic». At least once, the opposite is the case.

This hypothesis is a hypothesis of ambiguity, with a rough indication of a difference in meaning.

In chapter 2 and also in later chapters, Zaslavski takes great pains to make distinctions that he tries to clarify by expressions such as the following:

i ₄₅ , i ₄₆ , i ₅₃ , i ₅₄ , i ₅₅ , i ₅₉ , inf ₁₅ :	bourgeois democracy
inf ₁₂ :	slave democracy
i ₄₄ :	partial democracy
i ₄₆ :	imperfect and limited form of democracy
i ₄₉ :	democracy of the old form
inf ₁₉ :	democracy in the strict sense of the word
i ₅₁ , i ₆₄ , i ₆₅ :	authentic democracy
i ₆₂ :	democracy of a new type
i ₄₃ , inf ₁₈ , inf ₃₂ :	true democracy

The distinctions are closely related to Zaslavski's evaluations. The Soviet Union is the only denotatum of 'authentic democracy,' and it is said that it is the profoundest and most extensive democracy in the world (see i₆₃). What is said about authentic democracy seems always intended as praise. There is ample reason to suppose that Zaslavski never intends to say anything unfavorable about the Soviet Union. Thus, 'authentic democracy' may be considered something highly and consistently valued. We may accordingly rely on the hypothesis that if something unfavorable (in the supposed estimation of Zaslavski) is said about «democracy», the word is not used in the sense of «authentic (true) democracy»; if something unfavorable is said, the wide concept T₂ or some other concept is used.

The wide concept T₂ includes authentic democracies, but it is seldom

used without a qualifying phrase making the sentence tell something about a subgroup of T_2 democracies, such as «bourgeois democracies». The subgroups qualified in this way are never praised unconditionally. They are mainly valued as stages in the development toward authentic democracy. The denotata of the wide concept seem to be positively evaluated, but not as strongly as the narrower concept of authentic democracy.

Zaslavski's valuations are mentioned because, as we look for evidence of whether a given occurrence is an instance of T_1 rather than of T_2 or vice versa, the estimations cannot but play an important role.

Some of the implicates subsumable under T_2 are:

«The war established a perfectly clear demarcation line between democracy and enemies of democracy. The line coincided with the line between the war camps» (i_{27}).

«Fascism, which is a sworn enemy of democracy, declared war on all democracies, old as well as new» (i_{52}).

Let us now turn to occurrences more easily subsumable under the narrow kinds of connotations than under the wide ones.

Zaslavski says that the United States is a democracy (i_{30} , i_{38}), using the word in the wide sense (T_2), but he describes elections there and comments, «That is not democracy» (occ. 166, inf_{30}). Here we subsume under the narrow sense (T_1). In other words, we maintain as a subsumption hypothesis that Zaslavski intends to say something better expressed by certain plausible interpretations of «That is not authentic democracy» than by «That is no democracy, authentic or nonauthentic».

Zaslavski says that in a «true democracy» the power cannot be in the hands of a minority. Such a state can at most be «a partial democracy» (occ. 85, i_{44}). Maybe Zaslavski here means by «democracy» something in the direction of «authentic democracy». He in that case maintains that in a state in which the power is in the hands of a minority, not all conceptual characteristics of an (authentic, true) democracy are realized, but only some. Zaslavski may, however, also have meant to use a broad concept, or, as a third important possibility in this connection, he may have intended to use «partial democracy» and «true democracy» as two two-word designations incapable of being analyzed into a concept designation «democracy» with «true» or «partial» as qualifying words. Similar reflections are relevant to occ. 87, i_{46} : «imperfect and limited democracy».

VI. OCCURRENCE ANALYSIS

Occs. 85, 87, and 166 are the only instances that may be taken to support Zaslavski's using «democracy» in the narrow sense—and those sub-assumptions are uncertain. The word «democracy» in occ. 166 may be used as synonym for an adjective «democratic»: «This is not democratic!» «This is not in agreement with requirements of democracy even in the broad sense!» «This is a feature of U.S. society that makes it drop in degree of democraticity.»

There are many instances in which Zaslavski says that different forms of democracy must be distinguished, that Soviet democracy is a new, better form: that it is an example (the only one so far realized) of a new form, and so on. This usage is well documented by implicates, for example, implicates 17, 18, 40, 49, 62 and 64.

There is insufficient evidence, however, to say that Zaslavski ever uses «Soviet democracy» as synonymous with «democracy». He may have used it as a synonym for «authentic democracy», but the evidence is too meager to establish such cases with reasonable certainty. Our puzzling conclusion is that Zaslavski *says* that «democracy» means «power of the people, etc.» and he takes «people» to mean «the entire populace» in contrast to «a part of the people».²⁰ (cf. T₅(i₃₇)), but there is scarcely a single *clear-cut* instance of his *using* the word that way. Whenever he uses the word, he seems to apply it in order to express broader concepts, which presuppose rigorous requirements as necessary and sufficient criteria of 'democracy'.

In other words, we arrive at the conclusion that if the definitoid statements made by Zaslavski are meant to express something similar to a normative definition, it is a normative definition that he probably has not followed a single time in his work. If the definitoid statements are meant to express something similar to a descriptive definition with an intended field of application covering his work, it is an untenable description.

Zaslavski insists, as has been mentioned, that there are different forms of democracy, each having its peculiar characteristics. This might be interpreted to mean that a democracy is an authentic democracy, or a bourgeois democracy, or a slave democracy, or some other form of democracy. It cannot be democracy without exhibiting one of the peculiar, mutually exclusive, forms of democracy. A democracy must belong to such a subgroup. This interpretation may seem, however, to be an assertion too trivial to be attributed to Zaslavski. It is difficult to conceive a *rose in general*, a rose that is nei-

ther white nor red, nor any other color, and just as difficult to conceive a democracy having no other character than the conceptual ones. Zaslavski, perhaps, intends to stress that one should not identify certain subgroups of democracy such as bourgeois democracy with democracy. There not only may be, but certainly are, very different ones, for example, Soviet democracy.

Some of the occurrences of «democracy» without qualifications clearly do not lend themselves to any but rather broad interpretations—for example, when Zaslavski says that Athens was a democracy but a slave democracy (inf_{12}), or when he insists that fascism is an enemy of all forms of democracy, old and new (i_{52}). Consider further his assertion that democracy develops as do all other forms of society (i_{48}), and that democracy in a state with class struggle differs radically from democracy in a state without class struggle (i_{50}). It is difficult in these cases to believe that by the word democracy he means «Soviet democracy», «bourgeois democracy», or any other special kind of democracy. He does not intend to say that Athens was a «slave democracy but a slave democracy» or that authentic (or any other form of) democracy may be either classless or not. When he says that the Athenian Republic of was the first democracy (inf_5 and inf_6), he probably does not intend to say that it was the first slave democracy. It seems more probable that he thinks that in Athens for the first time certain phenomena were created that qualified for the title «democracy», but democracy having peculiar specific characteristics. He suggests what made him use the title «democracy» by speaking about the «democratic form of state administration» (inf_5) in Athens.

In this connection I think it appropriate also to mention his saying that «Soviet democracy is the historical rejection of bourgeois democracy» (i_{55}) and «Without bourgeois democracy there would have been no Soviet democracy» (i_{54}).

By means of highly speculative auxiliary hypotheses, one might bring the above implicates into harmony with the interpretation of Zaslavski according to which he never intends to use «democracy» for a fairly broad (general) concept, comprising kinds of subgroups of democracy, and therefore subconcepts such as 'bourgeois democracy'. If the pros and cons are weighed, however, the evidence favors a fairly broad interpretation, even if this (of course) also implies auxiliary hypotheses and certain disbeliefs in what Zaslavski himself seems to assert about his own usage.

VI. OCCURRENCE ANALYSIS

VI.14. Precization Possibilities of Broad Concepts, Especially Their Specific Conceptual Characteristics

In the foregoing, we have argued that Zaslavski talks about, but does not use, or at least very seldom uses, a narrow concept of 'democracy', by which «democracy» is intended to be used synonymously with «authentic democracy» and this again with «the power of the entire populace». On the other hand, he often seems to use a broad concept, designating something that is an authentic democracy or something else, 'a', which we so far merely have alluded to by the expression «nonauthentic democracy».

The determination of 'a' is highly speculative and so is, therefore, the determination of the broader kind of concept intended by Zaslavski. In the foregoing, we have not given evidence in support of any definite determination of 'a', but of the existence of two directions of precization, one in the direction of authentic democracy, the other in the direction of authentic or nonauthentic democracy. We now ask, What is the delimitation of the group of phenomena intended to be called «nonauthentic democracy», but still «democracy»?

The broad concept of democracy may be said to comprise two main subconcepts, authentic and nonauthentic democracies.

There are, in Zaslavski's text, some names of phenomena that he considers *subsumable* under the nonauthentic democracies, for example, designations of denotata and of subgroups of nonauthentic democracies:

Bourgeois democracy

Slave democracy

British democracy

U.S. democracy

The democracy of the Athenian Republic

The democracy of France in the eighteenth century

Democracies that are democratic in at least one but not in all aspects
(cf. occ. 5, i₈)

There are in the text also names of phenomena falling outside both groups, authentic and nonauthentic democracies:

Fascist states (i_{52})

The government of Hungary after Versailles

The government of Poland after Versailles

The government of Yugoslavia after Versailles

The government of Bulgaria after Versailles

The government of Romania after Versailles (i_4 and i_5)

If there is a line of delimitation between nonauthentic democracies and nondemocracies, we shall have to try to find it somewhere between the two groups of phenomena named in the above lists.

Let us try to determine the aspects in which a state can be democratic according to Zaslavski.

1. States may be classed according to how great a part of the entire populace «exercises the power». It is said about the Athenian Republic that a part of the populace, the free citizens, had (more accurately «exercised») the power (inf_{11}). The capitalists have the real power in bourgeois democracy (inf_{15}). Soviet democracy, the most extensive democracy in the world, is not only the power of the majority; it is the power of the whole people (i_{66} , i_{67}). But the boundary between nonauthentic democracy and non-democracy cannot, without qualifications, be said to be identical with the distinction between the total and a part of the populace having the power. Zaslavski says that democracy is neither an aristocracy nor a plutocracy (inf_2 , inf_3 , and inf_4). The aristocracy and plutocracy are, on the other hand, parts of the total populace. Lacking more specific indications of where the boundary should go, we propose the following hypothesis:

(A) A state is democratic if the power is in the hands of a fairly large group of the populace, and the more democratic, the larger the part.

To guide an estimation of what is «fairly large», we can offer two instances from Zaslavski's text: the number of free citizens of Athens compared to the total population; and capitalists in twentieth-century England compared to the total population of England.

If our hypothesis is to be applicable to inference 15, the capitalists must, in the view of Zaslavski, be considered a fairly large group in the to-

VI. OCCURRENCE ANALYSIS

tal population. That is, some minorities must be considered numerous enough to be called «fairly large groups of the populace».

To guide an interpretation of «power lying in the hands of somebody», we can offer Zaslavski's characterization of Athens: representatives of Athenian citizens took decisions on state administration by consultation and votes (inf₈).

2. Probably relevant to the decision of whether a state is democratic is which part has power, not just how great the part is. Thus, it is a plus in democraticity if the part having power is relatively poor and (once in the past, or in the present) underprivileged (inf₂ and inf₄). Let us try to formulate a hypothesis in which reference is made to poverty and lack of privilege.

(B) A state is democratic if the power is in the hands of the poor, or the poor and other groups. The greater the power of the poor and traditionally underprivileged, the more democratic the state is.

This concept 'democratic'—which is highly similar to one of Aristotle's—must, I suppose, be integrated into any broader concept covering the Zaslavski's intention over large fields of occurrences. He says that democracy is not a plutocracy, the power of the rich. From that statement one might expect that the United States and Great Britain would not be called «democracies» by Zaslavski, but actually they are. That they are so called makes it plausible that he would restrict «plutocracy» to extreme forms of what is generally called by that name,²¹ or that in these occurrences (occs. 14, 69, and 70, inf₂ and inf₄), he uses «democracy» for «authentic democracy». The latter is, however, less probable. (Cf. the quotation on page 339 as a whole.)

The importance to democracy of the populace's being, or having been, poor and traditionally²² underprivileged, is confirmed, I think, not only by occs. 14, 69, and 70, but also by occ. 6 (i₁₁). According to Zaslavski, the French people had a democracy in the eighteenth century. From the sayings of Zaslavski we may infer that this democracy did not exist before the outbreak of the revolution in 1789. Zaslavski scarcely means that a fairly large part of the French nation in the «democracy of the French people in the eighteenth century» had power just as had the free citizens of Athens. He would probably admit that not much voting was done and that no consultations of a fairly large part of the populace were carried out. But Zaslavski

may want to stress that poor and underprivileged people were involved, and that leaders tried honestly to make decisions in favor of the great majority of the population. This may be one of the important things that makes him call a phenomenon between, let us say, 1789 and 1795 a «democracy». If so, we obtain support for hypothesis (B) rather than (A).

Nevertheless, not every occurrence is subsumable under (B). Thus, what is said in the sentences before and after occ. 83 (cf. inf₁₅, page 358) is not consistent with the view that in any democratic state, power is in the hands of the poor or underprivileged.

The phrase «has the power» is especially vague and ambiguous in the wording of (A) and (B). However, it would probably be difficult to precise these phrases. Zaslavski says that the USSR is guided by the Communist party (inf₂₈), but the power is in the people as a whole (i₆₇, i₆₈). It is not necessary, as just mentioned, that there should be an *institution* by which power is legally vested in the entire populace.

The hypothesis that Zaslavski's intended use follows (A) or (B) is not only rather vague, but also rather uncertain. I cannot see any reason to maintain that it is well established. The evidence is too meager. Of rival hypotheses I think the following are of high interest:

- (1) Zaslavski uses «democracy» in a broad sense of «authentic democracy or state of society lying in the line of development toward authentic democracy».
- (2) Zaslavski uses «democracy» in a broad sense of «authentic democracy or phenomenon traditionally called democracy».

In favor of hypothesis (1) we mention that Zaslavski stresses lines of development, and especially the necessity of bourgeois democracy as a stage in the past development toward Soviet democracy (i₄₈, i₅₃, i₅₄). The present-day nonauthentic democracies are all conceived to be in transition to something else. A state like that of democratic Athens might, if existing today, not have been called democratic by Zaslavski, because it would in his century not represent a new stage of development toward authentic democracy.

Zaslavski mentions, as an argument for not talking about democracy in general, that the forms are changing (i₃₉, i₄₀). This might indicate that the word «democracy» is retained whatever the changes, the conceptually es-

VI. OCCURRENCE ANALYSIS

sential thing being its causal relation with the first democracy, the Athenian Republic.

Against this argumentation in favor of (1), it may be objected that there is not much in the text to suggest that *causal* development is meant. Zaslavski seems just as likely to mean a succession of phenomena resembling in more and more aspects authentic democracy, but not necessarily causally connected as events within a country during a century. The criteria for whether a state is a link in such a development may not be anything other than the criteria of (A) and (B) already stated.

If a causal relation were intended and no stress were laid on (A) and (B), the rule of the thirty tyrants would be a further development of the democracy of the Athenian Republic, insofar as that republic developed causally into the rule of the thirty tyrants.

The causal interpretation of (1) is also difficult because, if there are a number of stages of development toward authentic democracy, all representing democracies but not authentic ones, one cannot but ask how the first link of the chain is recognized as such. I assume that Zaslavski would maintain that causally there is no break anywhere, and the ability to single out the Athenian Republic as the first link in the chain probably owes to certain minimum criteria of being a democracy, not to assumptions of causal nearness or weight. Thus, we arrive at the criteria of (A) or (B) or a combination of these with a third:

(C) If a state is democratic at a time S_1 , when the criteria (A) and (B) are used, but its democraticity is doubtful at an interval S_1 to S_2 following upon S_1 , the continuity in time and space may be taken as an additional criterion of democraticity and the state may still be called democratic.

The evidence of an additional criterion (C) being used, is, however, very shaky, and I would not find it justifiable to adopt it alongside (A) and (B).

With regard to hypothesis (2), a similar hypothesis was used on page 361ff. to interpret certain implicates. The instances that Zaslavski offers of nonauthentic democracies are all, except one, states or societies called «democracies» within a main Western tradition. This may suggest that by nonauthentic democracies Zaslavski simply meant «the phenomena *called*

«democracy» within the literature of certain traditions». He may not have used criteria other than the verbal label itself.

Hypothesis (2) may be said to maintain that Zaslavski only *uses* «democracy» in some sense of 'authentic democracy', and that when the term «democracy» occurs in wider senses, he might have placed it in quotation marks or replaced it with «so-called democracy».

Zaslavski says that a democracy with class antagonisms differs radically from one without such conflicts (i_{50}), and that Soviet democracy does not resemble the old form of democracy (i_{49}). If this is meant to imply that the two groups of phenomena have no politically relevant conceptual characteristics in common, then there would be no general concept of democracy including both authentic and nonauthentic ones. The nonauthentic, insofar as they showed class antagonisms, would not be democracies but could conveniently be referred to by the expression «so-called democracies».

When Zaslavski speaks of a democracy in eighteenth-century revolutionary France (i_{11}), he scarcely has the opinion that it was an authentic democracy. It was far too short-lived and confused to develop into something that Zaslavski would be willing to call «authentic democracy». If we accept hypothesis (2), we must therefore assume that Zaslavski classifies what he calls «democracy in France» as a 'so-called democracy'. This is unlikely, however. To speak of a «democracy» in eighteenth-century France is not usual outside Marxist literature. Thus, his use of a term like «so-called democracy» could no longer be taken as involving what he calls «bourgeois democracy» and politically similar structures, but would have to include «democracies» in Marxist usage. «So-called» would refer to «so-called within some tradition or other including the Marxist». If such a usage were intended, one would expect to find evidence of a still greater variety of phenomena being classed under «nonauthentic democracies», but the «French democracy of the eighteenth century» is *the only* subsumption under nonauthentic «democracy» that leads outside a main Western trend of usage. This may be taken as an argument against the assumption that Zaslavski intends to mean by «democracies, nonauthentic» the same as «anything whatsoever called «democracy» at some time or other».

It may well be, however, that the fact of something's having been *called* «democracy» has made Zaslavski more apt to call it «democracy»—regardless of definientia of (A) or (B) or any other, nonlabeled definientia.

VI. OCCURRENCE ANALYSIS

Even if that is granted, however, something more is needed to make it likely that he intended the label to be a conceptual characteristic of «nonauthentic democracy».

The strongest argument against (2) and related hypotheses, I think, may be drawn from Zaslavski's discussion of the nonauthentic democracies as stages in a development toward authentic democracy, and his insistence that the nonauthentic democracies have something in common that makes fascism their common enemy (i_{52}), etc.

In sum, I think it justifiable to maintain that the hypotheses that Zaslavski intends to use sense (A) or sense (B) are more tenable than hypotheses (1) and (2).

It would be rash, though, to conclude that (A) or (B) can be maintained as a fairly well confirmed hypothesis. Either one is a good working hypothesis for further investigation, but it should not be considered alone. There are a vast number of other hypotheses more or less similar to (A) or (B) as regards definiens and field of intended application that are at least as plausible.

A hypothesis of some interest can be constructed by combining of the definientia of (A) and (B):

(A \vee B) A state is democratic if the power is in the hands of a fairly large group of the populace or if the power is in the hands of the poor and traditionally underprivileged. The larger the part having power and the greater the power of the poor and traditionally underprivileged, the more democratic the state is.

As a hypothesis covering all occurrences, (B) has to be excluded, but it has some plausibility in relation to small groups of occurrences. Hypotheses (A) and (A \vee B) are the only ones among those considered above that can be used as working hypotheses with maximum intended field of application—the whole body of the 192 use occurrences in Zaslavski's text.

Since the primary aim of this chapter is to give a *general* description of occurrence analysis, we need not continue this discussion.

VI.15. Precization Possibilities of Narrow Concepts of 'Authentic Democracy'

In the following we shall try to make our hypothetical descriptive definition somewhat more precise by looking for evidence of what Zaslavski

B.VI.15. Precization Possibilities of Narrow Concepts of 'Authentic Democracy'

means by one of the phrases of the definiens expression, namely «authentic democracy». This avenue of increasing the preciseness of our description of Zaslavski's usage seems more promising than concentration on the delimitation of concepts of partial democracy.

Using a graphic analogy, we may say that our attention is concentrated on the border of the inner circle. In the foregoing sections we discussed grounds for determining the outer circle boundary, but found very few.

Looking for this kind of evidence, we shall use «total democracy» as a synonym for «authentic democracy». The former is more apt to guide us because «authentic» may more easily be given meanings in isolation from «democracy», and when it is thus isolated, the burden of evidence once more falls on search for the outer circle. «Authentic democracy» may be interpreted as «a democracy (in a broad sense) that is as it should be».

Some hypotheses:

- H1: «Total democracy» means to Zaslavski the same as «a state of society by which the total populace, in contrast to only a part of it, determines policies in questions concerning the society».
- H2: «Total democracy» means the same as «total absence of privileges for a part of the populace of a state, the privileges being economic (economic goods being bestowed without compensation for services to the community) or in the form of exclusive or heightened access to media of influence (communication media, or voting and eligibility powers, or powers to influence the preparation of voting processes)».

VI. OCCURRENCE ANALYSIS

- H3: «Total democracy» means the same as «a state of society in which all available means of influencing the state of society are made to serve the interests of the total populace rather than any specific part of it».
- H4: «Total democracy» means the same as «a kind of organization of society by which the possibilities of each member of the community to influence decisions and policies affecting it are maximized».
- H5: «Total democracy» is a name of a state in which the highest degree of democraticity has been reached. A state is to be considered more democratic than another if there is a greater chance that policies serving the interests of all inhabitants will prevail over policies in the interest of only a fraction.

These expressions, I confess, seem rather lengthy, considering the low level of preciseness gained by them. We would, however, encounter a number of difficulties if we attempted to improve the level without launching forth into the thin air of hypotheses that can be neither confirmed nor disconfirmed.

Compared with other texts providing so-called «definitions of democracy», Zaslavski's text is conspicuously lacking in one-word characterizations of the genus category. Usually «democracy» is said to be a form of government, a way of life, a kind of society, a kind of state, and so on. When Zaslavski says that «democracy» is «the power of the people», it does not help us much to conclude that democracy is a kind of power. Zaslavski does not call democracy a form of government or rule. He says, however, «The Athenian Republic was a democracy. The people there *exercised* the power» (inf₆, inf₇). There is a fairly great stress not only on actual ruling—administration and exercise of influence—but also on the interests of the populace being served (cf. i₉, i₂₂, and occ. 158 with preceding section, quoted here on page 343). The populace is not said to «direct» and «guide»; these terms are reserved to characterize the activity of the Communist party (inf₂₈).

The resemblances and differences between the activity of the Communist party in the USSR and the activity of minorities in bourgeois democracies are not extensively discussed. This makes it difficult to precize «having

power» and related expressions in Zaslavski's definitoid statements and other important sentences. He does not seem to regard it as a practical possibility that antagonisms could arise owing to divergent interests between members and nonmembers of the Communist party (inf_{27}). It is, therefore, not warranted to look for precizations of his term «authentic democracy» in which the expression «having power» is precized in such a way that the operation of mechanisms for obtaining and keeping influence are stipulated *per definitionem*, for example, in the normative definition of «authentic democracy».

It seems that, according to Zaslavski, the Soviet Union is the only state or federation of states that has reached the stage of authentic democracy (i_{18} , i_{64} , i_{68}). This might be taken as justification for attributing to Zaslavski a concept of total democracy by which concrete, precisely delimited procedures in the Soviet Union were mentioned in the definiens expression. It would be untenable, however, to maintain that for Zaslavski «authentic democracy» and «the Soviet Union» are synonymous. Many of his statements, especially those stressing that democracy is always in development (i_{48}), make it plausible to think of total democracies as being able to undergo variation in space and time. The Soviet Union is only the first authentic democracy. Consequently, it is not justifiable to conceive characteristics of the Soviet Union as conceptual characteristics of 'total democracy' without specific evidence. That the Soviet Union has a certain characteristic according to Zaslavski is a necessary but not a sufficient condition of its being a conceptual characteristic of 'total democracy'.

The above-formulated five tentative precizations seem (to me) to express rather different concepts. In spite of that, we do not find substantially more evidence favoring one of them over the others. The evidence is in every case meager, so meager that we consider it unprofitable to discuss it at length. If compelled to choose, we would prefer H_3 , but this choice would probably largely reflect preconceptions, formed before our study of Zaslavski's text began.

The concept H_1 refers to the question «Who influences and who determines policies?» H_1 stresses that the people as a whole do the job. H_2 stresses absence of inequality, not only in influence, but also in more direct possibilities for gratification of needs. H_3 shifts the emphasis still more toward ends rather than means, stressing actual satisfaction of needs and interests according to principles of equality.

VI. OCCURRENCE ANALYSIS

H₄ reverts to means and stresses equal and maximum *possibilities* of influence of each person. It differs from H₁ mainly in the fact that H₁ stresses actual causal relationships, whereas H₄ speaks of possibilities (for example, by certain institutions) and precizes in one direction the metaphor of a total populace «determining» something.

H₅ introduces a scale «more democratic than», which might well be introduced in H₁–H₄ as well. It stresses *consequences* of decisions rather than the structure of power and influence within society.

The differences among the hypotheses are considerable if we measure them by the degree of differentiation of standpoints prevalent among political scientists and ideologists. This mirrors the uncertainty of our conclusions, and probably also a large degree of indetermination in Zaslavski's usage.

C. More on the Theory of Occurrence Analysis

VI.16. The Function of Assumption About Uniformity of Use

In the foregoing discussion certain kinds of relevant arguments were left out of consideration. This was done because, despite of their *great potential* power of confirmation or disconfirmation owing to a high degree of relevance, the amount of supporting evidence that can be collected from the text is very meager and doubtful. The kinds of arguments can be likened to cups placed far out on the arms of a balance scale. A small weight placed in one of the cups may outbalance great weights on the opposite side when the latter are placed at fairly small distances from the center of the scale—but, alas, there is no material or very little material at hand that it would be justifiable to place in the distant left cup rather than in the near right one, or vice versa.

A hypothesis may stand up well if the intended field of application is limited to a certain part of the occurrences or text. In other parts, other hypotheses may fit better.

We have in the discussion of certain hypotheses about usage implicitly assumed that Zaslavski uses «democracy» in, at most, not more than two different ways. We have not discussed the possibility that he uses it in several other ways, and that one can find material to show how the occurrences are well accounted for by multiple ambiguity.

There is a very strong argument in favor of *starting* our occurrence

analysis with step 4, without any hypothesis of ambiguity. The natural way to proceed is to try out one hypothesis on usage, and to refrain from taking up a new one until an occurrence is found that is difficult to subsume under the initial hypothesis. The evidence of plurality of meanings must go with analysis of a multiplicity of occurrences. Some of the occurrences considered in the foregoing sections suggest the existence of ambiguities, but for expository reasons those ambiguities were not mentioned. We shall now discuss to what degree they and their contexts warrant a partition of the text into various fields of application of hypotheses, each of which occupies only a part of the text. Let us consider some such hypotheses:

- H1: At occs. 73 and 74 (see page 356, inf₅, inf₆) Zaslavski uses «democracy» to mean the same as «state of society in which the people or elected representatives gather to decide questions of state by discussion and vote». This may also be the sense intended in occs. 75–77.

The hypothesis may account for occ. 78 as well. At least, the occurrence sentence does not need to be so interpreted that it disconfirms H1 as applied to occs. 73–77; it may be interpreted as «Slave democracies do not belong to a kind of democracy we designate by the word «democracy» when used for *our* kind of democracy, namely, authentic democracy». Zaslavski intends, in other words, to say that when he uses «democracy» for «authentic democracy», its sense is not identical with «democracy» as used in «slave democracy». If «slave democracy» is not taken as one technical term, but is interpreted as «democracy», subclass «slave democracy», then «democracy» as a designation of the wider class can be interpreted as indicated by H1.

- H2: «Democracy» as used in occs. 101–02 (i₅₀; see page 359) is by Zaslavski intended to mean the same as «authentic democracy or anything called «democracy» within the Western bourgeois tradition».
- H3: In occs. 86–123 Zaslavski intends to use «democracy» in the sense of «authentic democracy or a state of society lying in the line of development toward authentic democracy».

VI. OCCURRENCE ANALYSIS

In favor of H₁ it can be said that occs. 73 and 74 (see quotation, page 355) easily lend themselves to the construction that a republic is a democracy if there is democratic administration, this being a sufficient criterion of democracy, and a definitional one. The next text sentence, I think, can also be taken as confirming H₁. There, «to exercise power» seems to be taken as criterion, and considering the opening phrases of chapter 2 (see quotation, page 339), where «democracy» is said to be «the power of the people», it may well be taken as definitional. To exercise power seems, then, in the next sentence (quotation, here page 355) to be described in terms of electing representatives and voting.

When the Athenian Republic is termed a «slave democracy» (cf. occs. 76 and 77, page 357), the difference from authentic democracy can be thought of in terms of a limitation of electing and voting power within the total populace.

The crucial point to discuss now is whether hypotheses H₁–H₃ should be regarded as confirmed to such a degree that a partition of the total field of application is warranted. What is the status of the already discussed universal hypotheses (A) and (A v B) in relation to the restricted hypotheses H₁–H₃? What is the weight of arguments for and against a partition of the total field of application into a major field covered by hypothesis (A) or (A v B), and one or two small fields covered by H₁, H₂, or H₃? Such a partition amounts to a hypothesis that Zaslavski uses «democracy» in two or three ways.

At occs. 73 and 74, Zaslavski describes the administration of the Athenian Republic and says that this republic was a «democracy». It is, of course, tempting at this place to attribute a connotation to «democracy» in terms of the description of the Athenian Republic, but the connotations of hypotheses (A) and (A v B) are also applicable to occs. 73 and 74. There are no strong reasons to suspect that because Zaslavski at occs. 73 and 74 happens to discuss the Athenian Republic, he adopts a concept of 'democracy' with conceptual characteristics more or less identical to the characteristics of the Athenian Republic. His saying that it was a «democracy» (occ. 74) would then be of little interest in the general discussion about «democracies». It is more reasonable to expect a certain amount of *uniformity of intended use*, which makes the statement that the Athenian Republic was a «democracy» into a hypothesis of subsumption: the republic can be subsumed under a concept under which a number of other states or societies can be subsumed.

If H₁ is adopted, the statement would not in its pretensions differ much from a tautology: the Athenian Republic was the Athenian Republic.

Occs. 101 and 102 are subsumable under (A) and (A ∨ B) without serious difficulties. One may conceive (A ∨ B) as better adjusted to those occurrences than (A), but neither of them gets any disconfirmation by reference to occs. 101 and 102. One may, therefore, say that those occurrences do not motivate any abandonment of the universal claim of (A) and (A ∨ B).

In the case of H₁–H₃, as in many other cases, a hypothesis of discontinuity in the use of a term introduces serious disturbances into the general argumentation of the text. The presumption should in such cases be in favor of uniformity.

Apart from this argument for a presumption of uniformity of use, one may roughly formulate a very general one: if someone uses a term in a definite sense at one place, there will on the whole be a disposition to use the term in the same or a very similar sense at other places. Without such a disposition, communication would be difficult indeed.

If the field of application of H₁, H₂, and H₃ is widened, they are heavily disconfirmed: they cannot compete with (A) and (A ∨ B) in relation to broader fields. They presume a sudden discontinuity or discontinuities in use of the term «democracy». Such discontinuities may, of course, exist, but the presumption is against them, if special reasons are found for their invocation.²³

Applied to hypothesis H₁, the uniformity argument says that if «democracy» in some or all occurrences other than occs. 73 and 74 seems to be used otherwise than indicated in H₁, this justifies a presumption that «democracy» is used that way even in the intended field of application of H₁, that is, even in occs. 73 and 74. Thus, occurrences other than occs. 73 and 74 are relevant to the question of how «democracy» is used in occs. 73 and 74. Claim and relevancy must be distinguished.

When we say that the likelihood that the same sense is intended in occurrence number y as in occurrence number x is greater than the likelihood of ambiguity, the kind of hypothesis made can be written in our usual terminology:

«The likelihood of Syn(aP₁S₁, aP₁S₂) is greater than –Syn(aP₁S₁, aP₁S₂) if S₁ and S₂ are both part of the same text».

VI. OCCURRENCE ANALYSIS

Or better, if «occ. x» stands for «as used in occurrence sentence x of a certain text» and «occ. y» applies by definition to the same text, we can write:

«Given a pair of occurrence sentences selected at random from a certain text, the likelihood of $\text{Syn}(aP_1\text{Occ.x}, aP_1\text{Occ.y})$ is greater than that of $\text{-Syn}(aP_1\text{Occ.x}, aP_1\text{Occ.y})$ ».

If it is objected that, at least for the interpretations of «same meaning» adopted in the next chapter, this cannot hold or is at least highly speculative, I would answer that at least in the case of «a» in the formula standing for «democracy» and P_1 for Zaslavski, we have no reason to imply a definiteness of intention that would make it possible to distinguish, let us say, 100 different meanings within the text *La démocratie soviétique*.²⁴

The contention that one cannot expect the word ever to be used twice with *exactly* the same meaning either presupposes a much looser and wider connotation of «meaning» than is introduced in the next chapter, or applies only to well-delimited concepts in which small differences of meaning can be detected and mapped out in relation to an exact frame of reference.

VI.17. Assumptions About Definiteness of Intention

Painstaking occurrence analysis of cognitive meaning²⁵ may roughly be described as an analysis of intended meanings, but it would greatly increase the likelihood of misunderstanding if occurrence analysis were said to be an analysis of the exact meanings intended. It seems often to be implied that exact analysis leading to exact results is impossible if highly vague and ambiguous expressions are investigated. I should rather say that a number of formidable practical obstacles are met with in such cases, but none of principle.

The guiding hypothesis of the last sections has been that Zaslavski's usage follows two patterns. They can be indicated by two main directions of precization, one suggested by synonymity between «democracy» and «authentic democracy», the other by synonymity between «democracy» and «authentic democracy or nonauthentic democracy». The definiens expressions in these descriptive definitions have a comparatively low level of

preciseness, primarily because we do not presume Zaslavski's definiteness of intention to have been deeper than is normal in texts of a propagandistic nature.

The greater the preciseness of the definiens expression, the greater will be the number of items to be confirmed or disconfirmed by occurrence analysis. The total amount of evidence is, however, very small. This is another important reason for keeping the definiens expressions of guiding hypotheses on a low level of precision.

Comparing the guiding hypothesis (page 361) with H₁ (page 373), we find that the lack of preciseness of the former constitutes a fairly strong argument in its favor, but having confirmed to some degree that Zaslavski uses T₂ rather than T₁ throughout his book (page 361), we may proceed to state hypotheses of a somewhat higher level of preciseness. This is in accordance with the general procedure to circumscribe Zaslavski's usage within narrower and narrower borders until the coarseness of the object studied makes it unwarranted to proceed further, for example, until the limit of Zaslavski's definiteness of intention seems to be reached at every point.

It is, of course, highly speculative to decide where such limits lie on the basis of occurrence analysis. If Zaslavski had written a longer book on the same subject and we had 10,000 occurrences to analyze, the prospects of tracing his usage (in the fairly narrow sense of cognitive connotation) would be better. Two hundred occurrences cannot be viewed as a big number for our purposes. This we wish to stress, because judged from prevalent practice in analytical philosophy and opinion analysis, much smaller numbers of occurrences seem to be viewed as sufficient for establishing descriptive definitions with great pretensions of preciseness and tenability.

VI.18. Linguistics and Occurrence Analysis: Method of Opposites

Linguists may ask whether occurrence analysis makes use of the method of delimitation of meanings that is so fruitful in general linguistics and in philology. In those fields, to find out what an author means by a word, it is often convenient to ask, What is the word or designation for the opposite? By always looking for opposites and for how the term and its opposite or opposites mutually divide the semantical field, we can step-by-step delimit

VI. OCCURRENCE ANALYSIS

the meaning of each term. In no case is it possible to delimit the meaning of a definite term without investigation of the use of other terms.

From the foregoing discussions it should be clear that occurrences of «democracy» in which «democracy» is declared to be the opposite of something else, are particularly welcome to the occurrence analyst. It would, however, lead us astray if we were to take at face value such conventional opposites as are commonly supposed to exist. It is, for example, sometimes said that «monarchy» is an opposite of «democracy». If Zaslavski's text had contained an occurrence such as «No democracy is a monarchy», it would have been eagerly listed by the occurrence analyst. There is, however, no such occurrence. Zaslavski speaks about «bourgeois democracy» and mentions as an example the English «democracy». He would probably hold that some of the bourgeois democracies are monarchies. There is at least no clear evidence of a consistent opposition between «democracy» and «monarchy» in Zaslavski's terminology. Opposite authentic as well as nonauthentic democracies—in one of the terminological systems that might be attributed (not without some arbitrariness) to Zaslavski—we find what Zaslavski terms «fascist states». From occurrences we can infer that, for example, the government of Bulgaria after Versailles was not «democratic» in any sense that Zaslavski seems to make use of. By hypotheses about how Zaslavski conceived that government, we can obtain some evidence about general features characterizing governments being «antidemocratic».

One of the complicating factors is the existence of an adjective «democratic» such that a state held to be «democratic» in one single respect might be called a democracy (cf. occ. 5, i₈). This makes it possible for Zaslavski to use—sometimes—a very broad concept of democracy. At other times he seems to have more restricted concepts in mind. We shall therefore in any case have to consider a great variety of systems of opposites. It does not lead us anywhere to inquire about «the» opposite.

Many terms in occurrence sentences are relevant to the central term studied. Thus, the term «people» needs special attention. All occurrences of that term ought to be carefully considered, because «democracy» and «rule of the people» in some sense seem to be closely associated in the mind of Zaslavski. Thus, many terms that are not opposites of «democracy» need auxiliary analysis.

Close attention to all occurrences in which something is said *not* to be a

democracy, or is otherwise taken as «opposite» in some of the many senses of this term (cf. the logical «square of opposition»), is highly recommended in occurrence analysis, but the technique does not give the analyst an *open sesame* by which reliable conclusions can be rapidly obtained.

One of the reasons that looking for opposites is so important in philology seems to be that when usage is stable, single words often acquire as opposites other single words. Thus, there is often a pair of words mutually determining each other's meanings. A change in the one affects a change in the other. We get relatively simple semantical fields.

In semantical analysis of more or less technical and unstable terminology, there is much less time for such systems of single words to evolve. Designations consisting of several words play a much more important role. In Zaslavski's text we have a series of complex designations of central importance to the study of his use of «democracy»: «bourgeois democracy», «slave democracy», «authentic democracy», and many others.

There are some combinations that we may expect to be consistently ruled out in his terminology, for example, «fascist democracy».

He would, perhaps, not *use* the designation «monarchical democracy» or «plutocratic democracy», but this would not rule out the possibility that he considers many democracies to be monarchies or plutocracies. The variety of complex designations makes systems of opposites complex and unstable. Thinking about the opposite of «slave democracy», we may concentrate our attention on «not-slave democracies» or «slave not-democracies» or «not-slave not-democracies» or «not-(slave democracies)». In cases of a designation with three important words, the «not»'s can be placed in eleven different arrangements of the kind indicated. One may not expect that an author makes a consistent choice, but rather that he uses his key terms to suit the general argumentation according to rhetorical rather than logical rules.

Summing up, we should say that looking for opposites is a good rule of thumb to be recommended in occurrence analysis. The most important expressions functioning in one or more occurrence sentences as opposites (in some sense of this term) should be singled out and considered separately. This has not been done in the Zaslavski analysis as it is described above, but it was omitted for expository, not methodological, reasons.

A more complete description of an occurrence analysis of «democracy»

VI. OCCURRENCE ANALYSIS

would include subordinate occurrence analyses of all key terms in key occurrence sentences. Thus, we should list and investigate terms such as «people», «rule», «fascist», «aristocracy», and others.²⁶

VI.19. Concluding Remarks on the Connotational Occurrence Analysis

By means of occurrence analysis we have been able to correct the impression that one is likely to form of Zaslavski's usage if one limits the inquiry to his «definitions» or, more generally, to his definitoid statements. Those statements suggest a much narrower concept than do the rest of the occurrences.

We have also been able to suggest several possibilities of meaning of the term «authentic democracy», that are compatible with all occurrences but for which there is little differential evidence (evidence favoring one particular hypothesis over others in a group of hypotheses). The definiens expressions have a level of preciseness that we deem more satisfactory than that of Zaslavski's «power of the people, by the people, for the people», for example, but they are still too vague and ambiguous for serious purposes of classification of items into authentic and nonauthentic democracies.

Given the results of the analysis, which I personally regret are not more definite and far-reaching, the question is likely to be asked, Could not much more of importance be said about Zaslavski's usage on the basis of his text?

Certainly. We have concentrated on possible connotations of a single word. We do not doubt that to find such connotations is of great importance in any attempt at clarification and, more generally, in any attempt to raise the level of efficiency of communication for cognitive purposes, but this does not lessen the importance of other types of inquiries. It is highly desirable that painstaking inquiries of other kinds be undertaken in conjunction with the connotational occurrence analysis. The description of them does not belong to this chapter, however, so we shall limit ourselves to offering an outline of the kinds of inquiries we have in mind.

VI.20. Occurrence Analysis of Other Varieties

What are (the) conditions that Zaslavski would consider *necessary* to call something a «democracy»?

From sentences such as «--- is incompatible with democracy» and «There is no democracy if ---», one can infer that certain conditions are considered necessary. Some of the inferences mentioned above (i_{42} , i_{43} , inf_3 , inf_4 , inf_{30} , inf_{31} , inf_{32}) provide evidence of conditions *sine qua non*.

Likewise, it is fruitful to ask, What are (the) conditions that Zaslavski would consider *sufficient* for calling something a democracy?

We write «the» in parentheses to suggest that there may be an indefinite number of sets of sufficient conditions, and that there may be complete sets of necessary conditions corresponding to each set of sufficient conditions. (However, the sets of necessary conditions may have conditions in common.)

Some would maintain that if we know a complete set of necessary conditions, then the set expresses a connotation. If by a «*complete* set of necessary conditions» is meant a set the conjunction of which would give a connotation (interpretation) rather than any other kind of sufficient conditions, we must expect to find it difficult to pick out a complete set from a list of necessary conditions. If a set is meant the conjunction of which is *at least* a sufficient condition, but which might be more than sufficient, we shall have difficulties in picking out which sets correspond to just sufficient conditions.

These difficulties are just the kinds of difficulties we have encountered in the foregoing sections. The quest for connotations by means of lists of necessary and sufficient conditions therefore does not open up new fields of evidence.

Nevertheless, such a quest is well motivated because its by-product, the lists of conditions, is itself of value for its descriptions of «usage» in a broader meaning. Such lists indicate characterizations of democracy, basic evaluations and descriptions; and the necessary conditions listed are common characteristics of any democracy. Incidentally they may give suggestions for condensed characterizations in the sense of R-definitions (see chapter 4, section 11, page 195).

If, in addition to such descriptions, we can derive some information on the connotations of the word, the value of the lists is increased, but even without the addition, such lists may be useful.

If the lists are worked out in close connection with occurrences of the term «democracy», for example, one may call the inquiry an «occurrence analysis», but not a «connotational» one.

VI. OCCURRENCE ANALYSIS

For the sociology and social psychology of controversy, for ideology research, and for a myriad of related kinds of investigations, it is important to find out whether a given occurrence sentence of the term «democracy» correlates with appreciation or depreciation of «democracy» (whatever the term may connote). For each occurrence one may ask for symptoms of appreciation, first, in the view of the sender (Zaslavski), and second, in the view of various categories of receivers, for example, French Communists, French de Gaullists, French undecided voters.

Here there is no room for appreciative occurrence analysis, but some hypotheses concerning the results of such an analysis may be stated:

1. There is no single instance of «authentic democracy» (or any synonym) being used depreciatorily in the sense of «used in a sentence expressing something unfavorable about authentic democracy». This holds true if the (hypothetically) inferred evaluations of Zaslavski are used to delimit favorableness from unfavorableness. But it holds also for most of the groups that are prospective readers of the text.
2. There are a great number of instances of «authentic democracy» being used appreciatorily by Zaslavski.
3. The term «democracy», when used without qualifying attributes such as «authentic» or «bourgeois», is never used depreciatorily, but very often appreciatorily. It seems to differ from «authentic democracy» (cf. items 1 and 2) in degree and frequency of appreciations.
4. The terms «bourgeois democracy», «partial democracy», and so forth, marking democracies other than «authentic democracies», are almost never used appreciatorily. The exceptions are occs. 114 and 115 (see pages 341–42), where the bourgeois democracies are said to have been necessary for the development of authentic democracy.

These and other regularities in appreciation relations justify an inference from appreciation to connotation: if Zaslavski were to say something unfavorable about «democracy», it is likely that he would take «democracy» in wide connotations that included the bourgeois democracies. Care must be taken, however, to avoid first counting an occurrence as evidence of a wide connotation *because of* depreciatory contents, and then later justify-

ing the inference on the basis that the occurrence shows the correlation of a wide connotation with unfavorable content.

Terms such as «appreciation» need clarification. There is also an urgent need for criteria that make it fairly precise to say that a certain occurrence is an instance of depreciatory use. The foregoing are only casual remarks.

As a last form of analysis that we should like to call «occurrence analysis», we mention «occurrence analysis for prediction and explanation of usage», especially analysis that tries to establish short hypotheses on regularities of use that can be relied on to hold in the future.²⁷ To be more explicit:

In all the foregoing kinds of analyses, we have had the intentions or evaluations of the sender in mind, when talking about connotation, meaning, appreciation, and so on. We may, however, ask the following kinds of questions: From what rules will it, for me, be most expedient and secure to predict whether Zaslavski would call something a «democracy» or an «authentic democracy»? Which are the most easily recognizable, common, and specific characteristics of denotata of «authentic democracy», as this term is used by Zaslavski?

If I were to answer such questions without further inquiry, I would first of all use the following rule: if something is recognized as a specific trait of the state of society in the Soviet Union, it will be, by Zaslavski, appreciated and will, according to him, belong to the characteristics of authentic democracy in general or to a subclass of authentic democracies. That is, it may be predicted that Zaslavski would be willing to use the term «authentic democracy» or «being characteristic of a true democracy» about the trait in question. When Beard (1934) analyzed occurrences of «national interest» and found the expression to stand for «banking interest», and so on, he made, in our terminology, a prediction analysis. That is, he found rules by which to predict and explain a usage on the basis of regularities of the denotata.

If an author has the intention of following his definition, his subsequent acts of subsumption may be very difficult to predict on the basis of that definition because of its lack of precision, lack of definiteness of intention, and so on. It may be practicable to predict his use by means of certain psychological and sociological characteristics, such as his membership in certain groups, a dominant evaluation he has in common with others, or some propaganda purpose one can be fairly sure he is pursuing. If the defini-

VI. OCCURRENCE ANALYSIS

tion he intends to follow is fairly precise and if it belongs to a field of discussion such as hydrodynamics, his explicitly formed intentions may be much more trustworthy and fruitful evidence of future use—even if the terms are apparently emotionally and ideologically loaded (for example, «cold front» and other terms of meteorology). If, however, the psychological and sociological classifications of today are uncritically adopted, one may expect very deplorable results from the standpoint of the theory of interpretation and preciseness: we obtain counterpropaganda and propaganda against propaganda instead of cool, painstaking scientific analyses of communication. Thus, we get the kind of counterpropaganda consisting in utter neglect of the sender's intentions, and then claiming that what he means by a eulogistic term is synonymous with what the analyst thinks is specific of the denotata that the sender mentions. For example, «authentic democracy» might in a piece of propaganda against the Soviet Union be said to *mean for Zaslavski* «dictatorship of the Communist party sustained by secret police and concentration camps».

This is not the place to discuss problems of this kind. Suffice it to say that the importance of occurrence analysis in the search for connotations may be overestimated, and that anybody writing extensively about the subject may be suspected of having such an overestimation. The search for intended meanings may, however, also be underrated, and anybody making content analysis and other semantical and related inquiries without going into the question of connotations may be suspected of underrating its importance.

Finally, we have devoted so much space to connotational occurrence analysis because other kinds of analysis can make use of the procedures of connotational analysis and do not, on the whole, present so many difficulties.

VII

Introduction of a Group of Concepts or Tests of Synonymity

A. Concepts of Intrapersonal Synonymity

VII.1. Introduction

By a «concept of synonymity» we shall mean a concept with «synonymity», «synonymous», «sameness of meaning», «likeness of meaning», or closely related terms as concept designations.¹ This normative definition of «concept of synonymity» is such that no concept can *per definitionem* be ruled out as a synonymity concept on the basis of its conceptual characteristics (content). As long as the designation is «synonymity» or certain related expressions, it is, according to the above convention, a concept of synonymity. Thus, if someone were to introduce the term «sameness of meaning» by stipulating the conceptual characteristic 'sameness of length', we should have to include the latter concept in our family of synonymity concepts.

On the one hand, the proposed use of the term «concept of synonymity» is such that it makes a sentence of the kind «This is a concept of synonymity» rather trivial. Such a sentence says two things: that «this» is a concept and that it is expressed by a member of a small class of words—«synonymity» and others.

On the other hand, one may expect that many concepts of synonymity show common features—if they do not, one may ask, why should the designations be the same or closely similar? The history of designations suggests that such expectations are often frustrated. The amount of similarity may not be great, being merely the result of human caprice.

The terms «synonymity», «synonymous», and so forth, have had a

VII. INTRODUCTION OF A GROUP OF CONCEPTS

long history, and there is no evidence that they have been used in the same way by all users. On the contrary, there are conflicting normative and descriptive definitions and, probably, conflicting usages. At the time of Aristotle, e.g., «synonymous» seems to have had a meaning closely related to what now is often called «unequivocal».²

Some authors speak about «the» concept of synonymy as if there were one concept that is the real concept of synonymy, whereas other concepts, whatever their concept designations or conceptual characteristics, cannot possibly be the real one. We have no good reason, so far I can judge, to single out any definite concept in this way. This holds also in relation to «the» concept of cognitive or logical synonymy. Other authors have pointed out weaknesses inherent in some proposed synonymy concepts.

In this chapter we shall introduce a series of families of concepts. They happen to have certain features in common that make it convenient to use «synonymy» or closely related terms as concept designations. Not much emphasis is placed upon the tenability of this view concerning convenience, however. It may well be that, in the long run, it turns out not to be convenient to call them by the proposed name. Our contention is that each of the entities introduced is, at the time this work is being written, fruitful. They are at the moment useful in certain kinds of investigations. The question of naming the concepts is considered a minor issue.

The entities to be introduced are called «concepts». Perhaps «tests» (or «test-batteries») would be a better term, but it is not used, because it might lead to the assumption that something definite is tested by all the synonymy tests, namely synonymy. The history of misconceptions about intelligence tests has been a warning for us (see, e.g., Goodenough 1949: 97ff.).

There is no reason to expect a future state of affairs such that «synonymy» or «sameness of meaning» will express only a single concept.

«Synonymy» and the other, closely related terms are currently used in very different fields of investigation, for example, in lexicography and in the field of semantic systems in the sense of Carnap. At present, little evidence exists that a concept designated «synonymy» will be adopted in all fields and that no other fruitful concepts will be designated by that term. Perhaps such a state of affairs eventually will be reached, but there is currently no methodological advantage in trying to reach it.

In this respect, the search for one concept of sameness of meaning is on

the level of the search for one concept of intelligence, learning, suggestibility, memory, attention, social norm or ideology. Such vague and ambiguous key terms are important in research, but attempts to find, for example, a concept of intelligence that might once and for all give to that term a rather definite meaning have been unfruitful. The concepts of synonymy to be introduced here have certain features in common with so-called «intelligence tests». One may among psychologists speak of such tests without being accused of believing that those tests measure something definite, 'intelligence', which can be tested in various ways and is independent of any special procedure of testing.

In this chapter a number of concepts will be introduced which are, as far as we can judge, fruitful concepts in *present-day research*. Whether they will be fruitful in twenty years we do not wish to predict. Probably some will be discarded and new ones adopted.

VII.2. The N-Concepts of Synonymy: Synonymy Identified with Presence of a Rule Proclaiming Sameness of Sense

In this section we shall consider a direction of precization of ««a» means (not) the same as «b»». ³ The direction can be roughly indicated by the formulations (I) and (IA):

- (I) That an expression means the same as another means that there is a rule which says or implies that the two expressions are to mean the same.
- (IA) That an expression does not mean the same as another means that there is a rule according to which the two expressions do not mean the same.

For example, «prime number» and «*Primzahl*» mean the same because according to mathematical terminological rules, both shall designate numbers that are not divisible except by the number 1 and themselves.

Precizations and Elaborations

- (1.1) ««a» means the same as «b»» shall mean the same as «there is somewhere a completely and explicitly formulated rule that states (or implies) that «a» and «b» shall mean the same».

VII. INTRODUCTION OF A GROUP OF CONCEPTS

The parenthetical «or implies» suggests an alternative; let us call it (1.2).

Assertions that «a» means the same as «b» would, if (1.1) is adopted, not state anything more than that there exists somewhere a rule of a certain kind. If the distinction between rule formulation and rule expressed by the rule formulation is adopted, the existence of a rule somewhere would be the same as the existence of at least one (rule) formulation somewhere that expresses the rule. Geographical indications have a fairly clear meaning in relation to formulations (expressions), not to rules.

(1.3) « a_i means the same as «b»» shall mean the same as «there is a synonymic normative definition which stipulates that «a» shall mean the same as «b» within a field of application M_1 , and a_i belongs to that field».⁴

The formulation (1.3) concerns definite instances of an expression «a», namely, instance number i , defined by its place in a text or by other space-interval references.

Common to all three definiens formulations of (1.1), (1.2), and (1.3) is the use of a «that» phrase: «*that* «a» and «b» *shall* mean the same». To ensure subsumability, we must obtain information about how this phrase is to be interpreted. An obvious, but for most purposes valueless, way of getting rid of the subsumability difficulties is to declare that the definiens requirement is satisfied if, and only if, there is an announcement *sentence* of the form ««a» and «b» shall mean the same». Only if we had constructed a language and introduced a set of «semantic rules» in the sense of Carnap would such a declaration give useful concepts of sameness of meaning. In relation to natural languages one has to take up the question, How do we find and formulate fruitful criteria of the presence of a rule announcing *that* «a» and «b» shall mean the same?

Let us proceed to the discussion of certain possibilities of contradictions if one attempts to use the above normative definitions in practice.

Let us accept as a postulate, that if «a» means the same as «b», «a» cannot *not* mean the same as «b», and vice versa. If two rules are found, one saying that «a» means the same as «b», and one that «a» does not mean the same as «b», both (1) and (1A) are satisfied. That is, our postulate is violated.

Such cases of violation are easily constructed. There are incompatible

terminological rules for numerous expressions in scientific literature. To avoid these violations, we suggest the following reformulation:

(1.11) «*a*» means the same as «*b*» within the field of application *M*»
means the same as «there is a rule that announces explicitly that «*a*»
shall mean the same as «*b*» within the field of application *M*».

If there are two authors, one announcing that «*a*» shall mean «*b*» within his works, and the other announcing that «*a*» shall not mean the same as «*b*» in his, there will be no simultaneous confirmation of (1) and (1A).

If, however, the fields of application *M*₁ and *M*₂ partly overlap, the announcements are in conflict, and (1) and (1A), even if formulated in the light of (1.11), may be confirmed simultaneously.

To avoid this result, one might reformulate the definiens of (1.11) as follows:

(T 1.12) «There is a rule that announces explicitly that «*a*» shall mean the same as «*b*» within the field of application *M*, and there is no rule announcing or implying the contrary.»

A corresponding concept of synonymy applied to single occurrences may be introduced as follows:

(1.21) «*a*₁ means the same as «*b*»» means the same as «there is a rule that announces explicitly that «*a*» shall mean the same as «*b*» within the field of application *M*, and *a*₁ belongs to that field».

Using previously introduced terms, we can reformulate and elaborate the definiens expression of (1.3) and (1.21) thusly:

T 1.31 «There is a synonymic or interpretative normative definition, 'N', that stipulates or implies that «*a*» shall mean the same as «*b*» within a field of application *M*, and *a*₁ belongs to the field *M*, and there is no synonymic or interpretative normative definition announcing something that, *per definitionem*, cannot be realized without violating the normative definition 'N'.»

The most frequent cases in which the first and second, but not the third, conceptual characteristics are satisfied are perhaps those in which different authors propose different and incompatible N-definitions with

VII. INTRODUCTION OF A GROUP OF CONCEPTS

the same intended field of application. If a modified definiendum is introduced, « a_i means for P the same as « b »», and « a » in requirement 1 of the definiens is replaced by «« a » for P», such cases are subsumable (but of course under a new concept). There is no incompatibility between the announcement of one author that « a » shall mean b , for him, and that of another who announces that for him « a » shall mean non- b .

The normative definition of « a_i means the same as « b »» having (T 1.31) as definiens expression will be said to introduce «the concept of synonymy as presence of synonymy norm», or, in short, «*the N-concept (norm concept) of synonymy*» or 'N-synonymy'.⁵

By means of previously introduced symbols and a new prefix, assertions that an instance a_i of an expression « a » is N-synonymous with an expression « b » may be thus symbolized as N-Syn(a_i M_1 b M_2).

VII.3. Limited Fruitfulness of 'N-Synonymy'

The norm concept of synonymy is of very limited fruitfulness.⁶ We shall not use the concept in any other way than in formulating hypotheses that state that others use or do not use a concept similar to the norm concept of synonymy. The concept has the same kind of fruitfulness as that of 'real definition': for classification of concepts used by others. In a sense it may be said to be fruitful within the historiography of concept formation. Often, authors write as if in their synonymy sentences they try to express concepts of synonymy closely related to the norm concept of synonymy. The definiens (T 1.31) may sometimes be an interesting precization or transintentional precization of expressions such as «--- means the same as ---».

Lexicographers seem often to work as if they used a concept similar to our 'N-synonymy'. Thus, in dictionary articles dealing with technical terminology, their definiens expressions come from textbooks or technical papers in which the definiendum expression is introduced by means of normative definitions. Should a lexicographer be asked how he knows that his dictionary articles are correct, it is likely that he would merely cite his source for the definiens expression and add that the author quoted is considered competent. That is, the argumentation sometimes proceeds as if sameness of meaning as far as it is involved in lexicography concerns identity of the definiens expression in the dictionary with the definiens expres-

sion in a normative definition announced within a competency group. The concept of N-synonymy is therefore considered fruitful in attempts to describe what lexicographers are doing when writing dictionary articles about technical matters.

The strongest argument against any other than the historiographical use of the norm concept of synonymy may roughly be indicated by saying that it slurs over the fruitful distinction between presence of a rule and conformity with a rule. It is convenient to be able to say, «People announce rules, but the rules are not always followed in practice»—or in terms of definitions, «People announce their definitions, but one should bear in mind that they do not always follow them».

Suppose we adopt the norm concept of synonymy and find a sentence of the form «a is not always a b». If there is a normative definition covering the sentence that announces that «a» shall mean the same as «b», we should conclude that «a is not always a b» means the same as «b is not always a b». We would be unable to say, «If the normative definition has been followed, it is here stated that b is not always a b». Since this is nonsense, it is likely that «a» does not mean the same as «b» in this instance, in spite of the presence of the normative definition.

An example will make this point clear. Some authors use a normative definition of «prime number» or «*Primzahl*» such that, for plausible interpretations by ordinary readers, the number 1 would be subsumable. But from the occurrences of the term, it is more or less obvious that 1 is not taken as a prime number. Such a normative definition is, for example, the following: «eine natürliche Zahl, die ausser sich selbst und der Einheit keinen Teiler hat, soll eine Primzahl heissen».⁷

Only one part of the strongest argument against the norm concept of synonymy has so far been mentioned. The other part may roughly be expressed thusly: it is more convenient to use the following expressions as definiendum expressions if (T 1.31) is taken as definiens:

- (2.1) «a_i means the same as «b» according to N» or
- (2.2) «a_i means the same as «b» if N is followed» or
- (2.3) «There is a synonymic or interpretative normative definition such that a_i is covered by its field of application and such that, if that definition is followed, a_i means the same as «b»».

VII. INTRODUCTION OF A GROUP OF CONCEPTS

With this definiendum already established, useful verbal habits will be retained intact, and we get a fruitful concept. It will not, however, be called a «synonymity concept». The concept obtained by using (2.2) as definiendum and (T. 131) as definiens will be useful as a precization of sentences stating that something means something else *per definitionem*.

Instead of the definiendum expression « a_i means the same as «b»», one may use «According to an N-definition, a_i means the same as «b»». Retaining (T. 1.21), one gets a fruitful concept. It is important for many purposes to know whether an instance of an expression is covered by the intended field of a normative definition. The positive information that the instance is covered, and that the normative definition is such that, if followed, «a» means the same as «b», is of importance, first of all, in attempts to interpret «a». Provided we find it justifiable on psychological or other grounds to assume that the N-definition has been followed, interpretation of «a» is made easier provided «b» is fairly easy to interpret.

VII.4. N-Synonymity Hypotheses: How to Test Them

Roughly, one may say that N-synonymity hypotheses assert the presence of regulated usage of expressions and offer a key to understanding the rule governing the usage—or, more exactly, a rule that, if followed, would regulate the usage.

To establish an N-synonymity hypothesis, one has to point out a sentence, or certain sentences, and show that it expresses a synonymic or interpretative normative definition. *This involves interpretation hypotheses and elementary analysis, namely, a description of definitoid statements.*

If marginal references are vague or implicit, their interpretation offers many difficulties and uncertainties. Once we have established—with a greater or smaller degree of certainty—the presence of a synonymic or interpretative normative definition with marginal reference such that it covers the instance a_i that is under consideration, the next step is to establish by appropriate subsumption hypotheses that a_i belongs to the intended field of application of the rule. *This involves the kind of elementary analysis called «subsumption analysis».*

If positive results are obtained, the first two requirements of (T. 1.31) (page 393) are fulfilled. The third requirement offers peculiar difficulties

because its satisfaction requires disconfirmation of an existence sentence: one has to establish that there *does not exist* a second rule covering a_i such that, if that rule were followed, a_i could not also follow the first rule.

If one tries to find out whether the third requirement is fulfilled, important ambiguities of its formulation are revealed. Let us consider an instance of the term «probable». Because there is an intense interest in probability calculi and their application, philosophers, logicians, and mathematicians have produced a great many sentences that may be plausibly interpreted as synonymic or interpretative normative definitions covering *all* instances of «probable» produced after the production of the rule. That is, the theorists propose regulations for the use of the term «probable» without making any exceptions: the term shall mean this or that, whether produced by the framer of the regulations or not.

Consider this example of an argumentation pattern suggesting use of a concept 'normative synonymity': «--- another term which also antedates Lankester's paper of 1870 is *heterology*, proposed by E. D. Cope (1868) to designate «what Swainson and others called 'analogy' as distinguished from affinity». This very definition proves Cope's term to be synonymous with homoplasy, as here understood» (Haas and Simpson 1946: 281, 329).

It appears that Haas and Simpson consider Lankester to have proposed (something closely similar to)⁸ a normative definition of «heterology». They seem to quote the definiens expression of that normative definition, and seem to think that the content of the quotation is sufficient evidence for the reader of their paper to accept their hypothesis that «heterology» is synonymous with «homoplasy».

In the paper, Haas and Simpson do not formulate a normative definition of «homoplasy» with a definiens expression identical to the quotation from Lankester's paper. They do, however, use several slightly different expressions, and these expressions occur in their argumentation for or against preferences concerning the interpretation of «homoplasy». Therefore, one may consider that Haas and Simpson compare Lankester's definiens expression with a definiens expression they do not formulate explicitly but consider indicated sufficiently accurately in various sentences preceding the quotation from Lankester.

Haas and Simpson's text permits (of course) precisations in various directions. It is here only contended that one of these directions

VII. INTRODUCTION OF A GROUP OF CONCEPTS

leads to the hypothesis of N-synonymy between «heterology» and «homoplasia».

VII.5. The Ds-Concepts of Synonymy: Synonymy Identified with Reported Sameness of Meaning

This section will be devoted to the exposition of certain N-definition possibilities, some of which furnish fruitful concepts at the present stage of research.

Let us consider the following rather than obscure formulations:

- (i) That an expression means the same as another means that they are by competent people said to mean the same in use.
- (iA) That an expression does not mean the same as another means that they are by competent people said not to mean the same in use.

Rough example: «*Primzahl*» and «prime number» mean the same. That is, some or all mathematicians say that usage is such that they mean the same.

By means of precisizations and elaborations of the definiens expressions in (i) and (iA), concepts can be constructed that are fruitful within rather limited inquiries and expositions. Consider the following examples:

- (i.1) ««a» means the same as «b» for P» shall mean the same as «there is an assertion by the competent person P to the effect that, as used by him, «a» means the same as «b»».

This stipulation gives us an intrapersonal synonymy concept. Corresponding interpersonal concepts are of doubtful use.

- (i.2) «Syn($aP_1S_1bP_2S_2$)» shall mean the same as «there is an assertion Syn($aP_1S_1bP_2S_2$) by the competent person P_1 ».

The term «competent», here left unprecized, is, of course, in need of clarification, preferably in the form of tests. In the following, we presume that no conventions are adopted that assert that a certain person is competent, thereby *implying* that his hypothesis Syn($aP_1S_1bP_2S_2$) is true or tenable. The conventions would normally refer to competency in using a lan-

A.VII.6. Ds-Concepts of Synonymity Introduced by Reference to Questionnaire Procedures

guage and in talking about it. Formulation (1.2) might therefore be reformulated as follows:

(1.21) «Synonymity sentences» shall be used synonymously with
«sentences saying that there is an assertion expressed by the
synonymity sentences uttered by a competent person».

To adopt (1.2) or (1.21) as an expression of normative definition and to decide to use either would be highly inconvenient. We need distinctions of the kind now expressed by saying, for example, «The hypotheses that the English expression «a» means the same as the English expression «b» is highly misleading or even untenable, in spite of the fact that the hypothesis is asserted by all specialists in English usage». We need the distinction between the hypothesis that some or all competent people assert or are willing to assert a certain synonymity hypothesis, and the synonymity hypothesis itself.

For purely expository purposes, the expression ««a» is for P_1 in S_1 synonymous with «b»» may sometimes be used instead of « P_1 has [under certain standardized conditions] affirmed that he, in the situation S_1 , interprets «a» to mean the same as «b»».

In the next section certain questionnaires about usage are considered. In protocols describing the results of these questionnaires, expressions of the above kind occur so often that abbreviations are desirable. It has proved convenient, and not liable to misunderstanding, in the exposition of such questionnaire results to use an abbreviation that, under other circumstances than those of its application, would slur over the highly important distinction between hypotheses of usage and hypotheses stating that certain such hypotheses are made by competent people.

VII.6. Ds-Concepts of Synonymity Introduced by Reference to Questionnaire Procedures

Questionnaires of Type Qs1

By the term «Qs1 questionnaires» we refer to questionnaires that, roughly speaking, invite a person to read a text. In the text there is an expression T. After having read the text, the respondent is asked to imagine that the ex-

VII. INTRODUCTION OF A GROUP OF CONCEPTS

pression T does not occur there, and that an expression U occurs in its place. He is then asked whether he would have interpreted U to mean something different from what T meant to him when he read T.

Questionnaires of this kind, Qs_I, are obtained by selecting definite texts and a definite ordered pair of expressions, T and U. These expressions are called the «crucial» expressions.

A group of Qs_I questionnaires, which I and others have used, are translated from their Norwegian formulation as follows:

Qs_I, No. ---.

The analyst (carrying out the test) invites a respondent to read carefully a text presented to him.

After the respondent has read the text, the analyst says: This text was offered you as an example of a text that contains the expression «---». Let us call the expression T. What I should like to know is the following:

Imagine that the expression «. . .»—let us call it U—had occurred at the place that T occupies in the text and instead of it. Would U have expressed the same assertion to you as did T when you read T?

The last question is called «the synonymity question» of the questionnaire. Sometimes the questionnaire is given in written form. In that case, the respondent is asked to read the questionnaire line by line, not skipping ahead to read formulation U before T.

Qs_I is so worded that the respondent is talked about as a different person from the analyst. In analytic philosophy and lexicography, processes are sometimes performed by which the analyst asks himself the synonymity question or closely related questions. A slight modification will make Qs_I adapted to those cases.

Qs_I and all the other questionnaires of this section are adapted to intrapersonal relations. Respondents are asked about their own usage. Sometimes the additional instruction is given that we as analysts are only interested in what we ask about, not in how respondents believe that other people interpret the crucial expressions T and U.

The questionnaire described above is adapted to cases in which T and U may be expected to express assertions. That is, T and U are usually declarative sentences. An important modification has been made for cases in which T and U are designations. This subclass of Qs_I questionnaires we call Qsd_I questionnaires, where «d» stands for «designation». All of them have the same form:

A.VII.6. *Ds-Concepts of Synonymity Introduced by Reference to Questionnaire Procedures*

Qsd1. No. ---.

Text: ---.

Instruction: This text was presented to you as an example of a text containing the expression «---» [for example, «true»]. Let us call the expression T. What I should like to know is the following: Imagine that the expression «. . .» [for example, «quite sure»]—let us call it U—had occurred at the place of T in the text. Would the sentence containing U have expressed the same assertion to you as the sentence containing T did when you read T?

If we presume the respondents to be honest, a positive answer to a Qs1 questionnaire registers what certain persons believe about their usage. More precisely, a positive answer—if it is an answer to the question as intended by the analyst—registers that a person believes that if the questionnaire had contained an expression U instead of an expression T, this would not have made any difference to his interpretation.

Just what the respondent believes is uncertain, and his definiteness of intention may sometimes be extremely low. There are, however, important regularities in respondents' answers, and we feel fully justified in using the answers in studies of communication. The regularities are such that we may conveniently introduce some concepts of synonymity by means of the questionnaires.

'Qs1A-synonymity' is N-defined as follows:

- (1) By «T and U are Qs1A-synonymous for P in relation to S» we shall mean the same as «Confronted with a Qs1 questionnaire with T and U as crucial expressions and the text N, P answers positively».

Analogously, Qs1A-heteronymity is N-defined by negative answers.

The symbol S is that of situation, which here is delimited to the test situation in which P is confronted with a definite text and a synonymity question.

The concept is introduced in relation to a definite text. One might consider, as an interesting generalization, whether P would answer positively no matter what text T and U were put into. In general, one may expect that certain texts S might be found that would reverse P's answer.

We have not found it convenient to introduce a concept of such a kind that an assertion «T and U are for P in S Qs1-synonymous» means the same as «P answered positively when confronted at time t_0 with Qs1, ---». That is, we do not by the subsumption intend to limit our assertion to what hap-

VII. INTRODUCTION OF A GROUP OF CONCEPTS

pened at a definite instant, the moment t_0 when P answered positively, for example, by saying the one word «Yes». On the other hand, it is unlikely that any person would answer the same every year until his death. In the wording «P answers positively» of the definiens formulation in (1), the indefiniteness of the present tense leaves the door open for precizations in various directions, several of which may be of interest. In any case, a positive answer to a Qs1 question at a given moment shall, by definition, be taken as a (direct) confirmatory instance in relation to the hypotheses «T and U are in relation to S Qs1A-synonymous». If the test is repeated later, a second positive answer will be taken as another confirmatory instance.

Would it be adequate to say that by means of the questionnaire Qs1 and the concept 'Qs1A-synonymity', the term «synonymity» is operationally defined? It would not, in our opinion.

We do not intend, by the introduction of 'Qs1A-synonymity', to furnish one definite concept that in the future should be intended when we use the term «synonymity». We do not try to define synonymity operationally, if this expression is taken to imply that we look for a single concept by which the term is introduced in relation to a definite set of operations. We do not introduce, by (1), any concept 'synonymity', but a concept 'Qs1A-synonymity'. The word «synonymity» makes up the second half of our conceptual designation, not the whole of it. We only contend that some of the hypotheses that so far have included the term «synonymity» concern subject matters that make it fruitful to leave out the term «synonymity» as a complete designation and talk about Qs1A-synonymity instead. Thus, the relation between «synonymity» as used so far—for example, in «synonymity sentences»—and «Qs1A-synonymity» is much less intimate than in operationism.

When we try to use the material obtained by means of Qs1, the question immediately arises, Does the respondent understand the questionnaire approximately in the sense that the analyst intends it to be understood? Or are there indications that the answer is an answer to a rather different question from the one the analyst tried to communicate? We may affirm that T and U are Qs1A-synonymous without worrying about this point. There is need for a second concept, one much more difficult to handle than 'Qs1A-synonymity'.

(2) By «T and U are Qs1B-synonymous for P in relation to S» we shall mean the same as «Confronted with a Qs1 questionnaire with T and U as crucial expressions and the text N, P answers positively.

A.VII.6. Ds-Concepts of Synonymity Introduced by Reference to Questionnaire Procedures

In addition, the answer is an answer to the synonymity question interpreted as intended by the analyst».

An answer that directly confirms a case of Qs1A-synonymity does not necessarily confirm a case of Qs1B-synonymity. One must somehow obtain information about how the respondent has interpreted the questionnaire. The problem may be reduced to one of finding out whether certain interpersonal synonymity relations hold true. In part B of this chapter, some procedures are outlined by means of which one may acquire information of this kind. As long as no such procedures are outlined and connected with the intended meaning of (2), we do not regard «Qs1B-synonymity» as a designation of a workable concept in a theory of communication.

If fairly simple procedures were available for establishing interpersonal synonymity relations, we would not have bothered to introduce a concept like 'Qs1A-synonymity'. However, interpersonal synonymity hypotheses are problematic to such a degree that 'Qs1B-synonymity' is highly difficult to test. The test involves many doubtful auxiliary hypotheses. Because of these difficulties, 'Qs1A-synonymity' will be extensively used.

Questionnaires of Type Qs2

As questionnaires of kind Qs2, we class, roughly, those that invite the respondent to place an expression, T, in various imagined situations, and to consider for each situation whether he would have interpreted another expression, U, to express the same assertion that he considered T to express in those situations, provided U had occurred instead of T.

Qs2 has been used by myself and others as a supplement to a single Qs1 questionnaire or to a series of Qs1 questionnaires in which T and U have been held constant and the text has been changed. By using Qs2, the analyst asks much more of the respondent than he does by using Qs1. The answers should be taken with correspondingly more reserve. The material we have so far gathered by means of Qs2 questionnaires has, perhaps, been more useful for analyzing the limitations of questionnaire methods than for mapping out beliefs concerning the expressions T and U.

The first subtype of Qs2 questionnaires reads as follows:

Qs2. No. ---.

Let us consider the two sentences T and U.

VII. INTRODUCTION OF A GROUP OF CONCEPTS

T: ---.

U: ---.

Suppose you heard T uttered by a person who clearly put forth T as an assertion. Do you think you would interpret T in such a way that it expresses the same assertion as U, if U had occurred in the same context in which you in fact heard T uttered?

Suppose you hear T uttered under different circumstances, but always in such a way that it is considered to be uttered by a person who clearly puts forth T as an assertion. Underline that answer of the following three that you eventually believe is the right one:

Yes. In all situations of the kind mentioned.

Yes, in some, not all, such situations.

No. Not in any such situations.

The respondents answering Qs1 and Qs2 were encouraged to write comments, and from them the analyst could infer that, frequently, a kind of misunderstanding existed that reduced the value of the answers. Roughly, the respondents may be said first, to consider T in a definite context and then to consider how they would feel and think if somebody substituted U for T in that context. They immediately pose the question, Why should U be preferred to T? and they find that if T and U meant the same, T would not have been replaced by U. In other words, the respondents imagine the whole time that both T and U are already present within a situation prior to their being placed together in the questionnaire.

To avoid the confusion resulting from misinterpretation of the questionnaire, the analyst added the following instruction to Qs2:

Consider that you hear T uttered by a person who clearly puts forth T as an assertion. Consider, further, that he then utters U, either directly after T, or in a later part of a conversation or discussion.

The questions of Qs2 *are not concerned with such situations* in which you, within a certain context, hear T and, after that, U. The questions refer to definite contexts in which *only one of the formulations*, T, occurs. We ask you to imagine that U had occurred in the place of T, and ask you whether you would interpret T in such a way that it to you would express the same as U would have expressed to you if U had occurred in the place of T.

Referring to a particular set of questionnaires, Qs2 No. 1 and Qs2 No. 2 (quoted in chapter 8), in which T and U differed from each other only insofar as the one contained the expression «all numbers» and the other «all whole numbers», the additional instruction ended up with a related example:

A.VII.6. *Ds-Concepts of Synonymity Introduced by Reference to Questionnaire Procedures*

The following note in an answer is attributable to the misconception that we are concerned with a context in which a person exchanges T for U: «The person who puts forth T must have had a motive to precize «all numbers» by means of «all whole numbers». Therefore, I would not conceive T to express the same as U in any situations.»

Even with these additions, there were still persons who misconceived the intention of the analyst, and a new version of Qs2 was made. This version is identical to the original version except for the second sentence of the second paragraph. It reads in the new version:

Suppose you in that context had heard U uttered instead of T. You *only* hear *the one* formulation *not* first T and then U.

To what extent these reformulations helped convey the analyst's intention to respondents is discussed in chapter 8. The misconception considered above may be said to owe to the respondent's tendency to mix together his job as analyst with his job as an average member of a language community. As an analyst, his attention is focused on two expressions, T and U, within a particular kind of situation, but his job in this situation is to imagine situations in which T and U occur separately. The associations T and U released in the metalanguage of the questionnaire are taken to be associations that would also have been elicited if either T or U had occurred in the object language.

Just as two concepts, 'Qs1A-synonymity' and 'Qs1B-synonymity', were introduced in relation to the Qs1-questionnaires, we may introduce two analogous concepts 'Qs2A-' and 'Qs2B-synonymity' in relation to Qs2. Differences in results from different modifications of Qs2 may justify introducing the concepts by one definite version, for example, the third, which seems to cause the least amount of misunderstanding.

Questionnaires of Type Qs3

The questionnaire Qs2 does not ask respondents to imagine any kind of situation in which the crucial expression T might occur, but rather to limit their attention to cases in which T is used to express an assertion. Qs3 is simply Qs2 without that restriction. Qs3 was used mainly because we needed to use imperatives as crucial expressions.

Because Qs3 differs slightly from Qs2 in other ways, we shall quote the first version of Qs3 in toto:

VII. INTRODUCTION OF A GROUP OF CONCEPTS

Qs3. No. ---.

Let us consider the two sentences T and U:

T: ---.

U: ---.

Imagine that you utter, read, or hear T in some connection or other. Do you believe you would interpret T in such a direction that by T was meant the same as you would have understood by [Norwegian, «*lagt i*»] U, if that sentence had occurred where you in reality read or heard T?

To arrive at a reliable answer, imagine that you find or use T under different conditions.

Underline the answer you think is adequate (if any of them is adequate):

Yes. In all situations.

Yes. In some situations, but not in all.

No. Not in any situation.

To prevent the misconception arising from the respondent's imagining situations in which someone substitutes T by U, the analyst inserted a warning in the questionnaire, as was done in the third version of Qs2.

VII.7. Truth-Condition Concepts of Synonymity

In this section we shall consider some concepts with close relations to criteria of meaningfulness proposed by Pierce, James, Wittgenstein, Schlick, Carnap, and others.

Our preliminary formulations are:

- (1) Two sentences shall be said to mean the same if, and only if, the conditions under which the one is true are identical with the conditions under which the other is true.

An analogous formulation may be introduced for «not mean the same». The term «identical with» is replaced with «different from».

The extensive literature on criteria of meaningfulness and related issues contains material for precization and elaboration of (1) in several directions. The literature also offers valuable material for estimation of difficulties, theoretical and practical, that confront those who accept concepts related to (1) as a basis for normative or descriptive definitions of sameness of meaning. This is not the place to discuss that literature.

Let us consider the following possibility of a normative definition:

(2) «The sentence «a» for P_1 in S_1 means the same as the sentence «b» for P_1 in S_1 » means the same as «There is no set of conditions under which P_1 in S_1 would hold «a» to be true and not «b», or hold «b» to be true and not «a»».

Heteronymy might be introduced by a formulation like (2), except that instead of «there is no set» one would write «there is at least one set».

In philosophic and other debates in which (1), modified in the direction of (2) or in other directions, has been used to clarify meanings, it has been customary to ask people (believed somehow to be competent, for example, members of the Vienna Circle) whether expressions «a» and «b» fulfill the definiens requirement. In the case of a positive answer, one has considered it established that for the persons asked, «a» and «b», as occurring in S_1 (or in general), mean the same.

Accordingly, the following reformulation of the definiens of (2) might furnish the basis for a synonymy concept:

«Confronted with the question «Is there a set of conditions under which you, P , in S_1 would hold «a» to be true and not «b», or hold «b» to be true and not «a»?», P answers negatively.»

In relation to some important classes of sentences, such as predictions and complicated theories in the physical sciences, many people have difficulty applying the term «true». They seem to have no settled habits covering the use or interpretation of the term «true» outside certain subject matters, let us call them «matters of fact». Even in relation to such matters, there are difficulties of interpretation. To accommodate people having these difficulties, we have used the term «accept as tenable» or the shorter «accept». It is our feeling that thus modified the question furnishes a fruitful concept in many discussions concerning meaning. It seems at least to have considerable pedagogical value.

In practice—for example, in the philosophical seminar of Moritz Schlick in Vienna—truth-condition concepts were used as if based on a questionnaire. As an important step in the logical clarification of sentences used in a discussion, the users were asked to compare truth conditions of two sentences. If the users answered by reporting the same conditions for the two sentences, this was taken to mean that the sentences for those users

VII. INTRODUCTION OF A GROUP OF CONCEPTS

meant the same. Let us by the term «truth-condition questionnaires» refer roughly to such procedures of questioning.

Many versions of such questionnaires have been tried out. Here is one of them:

Qs5. No. ---.

Texts:

(1) ---.

(2) ---.

From these texts it is seen that they are different only insofar as one sentence in (1), let us call it T, is replaced by another one in (2), let us call it U₁.

Question 1:

Can you imagine circumstances (conditions, situations) in or by which you would accept T and reject U₁, or vice versa? Or, would you either accept both or reject both under every conceivable situation?

In the questionnaires of type Qs5 that so far have been used, further questions were added. They differed from question 1 only in that new formulations, U₂, U₃, . . . , were introduced, one in each new question.

Taking the answer that either both or neither of the formulations T and U₁ must be accepted as direct instances of confirmation of synonymy, we arrive at a concept, let us call it «Qs5A-synonymy». If the requirement is added that the respondents should have interpreted the questions as intended by the analyst, a concept 'Qs5B-synonymy' is introduced, corresponding to the concepts 'Qs1B-synonymy', 'Qs2B-synonymy', and so forth.

Another version of truth-condition questionnaires makes use of the expression «accept as true» instead of simply «accept».

A set of versions rather different from Qs5 has the name «Qs4 questionnaires». Here is one that has been used, with results reported in the next chapter:

Qs4. No. ---.

Text: ---.

Instruction: This text was presented to you as an example of a text containing the formulation «---» (T).

What I should like to know is the following:

- 1a. Do you consider it a necessary criterion of the truth of T, that «---» is true?

- 1b. Do you consider it a sufficient criterion?
- 2a. ---.

Questions 2 and 3 only introduce new comparisons, corresponding to U_1, U_2, \dots , in Qs5.

Some respondents were unfamiliar with the expressions «necessary» and «sufficient» criterion, and an explanatory note was added. While this note settled certain uncertainties, it also created fresh ones.

In questionnaire Qs5 the respondent is invited to use his imagination. It happens that the imagination is not used in such a way as would seem fruitful for the clarification of verbal habits. After studying controversies in which certain formulations, T and U, play an important role, the analyst may be in the position to help the respondent in the use of his imagination. He may present the respondent with a list of formulations representing conditions likely to be conceived to be relevant to T and U, and ask the respondent, for each condition, whether he, assuming the condition to be realized, would accept both T and U as true or reject them as false, or make a distinction between them. Such a questionnaire (Qs6) is of value before Qs5 is applied.

Here is a version of Qs6.

Qs6. No. ---.

[identical to Qs5 up to question 1; then:]

Consider the list, L, of formulations. Please answer, in relation to each member of the list, the following questions.

- 1a. Assuming this sentence, as interpreted by you, to be true, would you accept T as true?
- 1b. Or, as false?
- 1c. Assuming the sentence, as interpreted by you, to be true, «accept as true» is substituted by «reject as false».
- 2b. . . .

Questions 3a, 3b, 4a, and 4b are worded correspondingly, except that «accept as true» is replaced with «reject as false».

A concept 'Qs6LA-synonymy' may be introduced by taking identical answers to questions 1a, 2a, 3a, 4a and questions 1b, 2b, 3b, 4b as direct confirmation of synonymy of T and U for P in relation to the particular list L.

VII. INTRODUCTION OF A GROUP OF CONCEPTS

A more interesting concept may be introduced, which requires that T and U are synonymous, provided that no matter what list is presented to P, the answers would be as indicated above.

VII.8. Truth-Condition Concepts, Verification, and Certainty

When respondents read questionnaires Qs1, Qs2, and Qs3, the phrase «express the same assertion» absorbed much of their attention. They often felt justified in asking for explanations or precizations. In this situation it was tempting to resort to an explanatory note introducing the truth-condition criteria, but in the long run it was preferred to let Qs1, Qs2, and Qs3 function as independent questionnaires.

In the preceding section we gave some suggestions about the difficulties of application that make themselves felt when truth-condition criteria are adopted. Here we shall mention a difficulty of some philosophical interest.

It seems that many people, when invited to imagine circumstances under which they would consider T to be true, try to imagine circumstances under which they would consider T ultimately or definitively verified—in some senses of these difficult terms. Among such persons there are differences of opinion as to the existence of circumstances under which it would be justified to consider T ultimately verified. These differences of opinion, which play such a prominent role in philosophical debate, make themselves felt even among high school students.

These interpretations and opinions introduce difficulties for analysts in understanding and comparing the answers to truth-condition questionnaires.

Some respondents who try to imagine circumstances of ultimate verification of T seem to ask themselves whether these conditions are such that they represent ultimate falsification of U. The answer is naturally negative for nearly any pair of sentences, T and U, likely to be compared. Or, the circumstances of ultimate verification of T are compared with circumstances of not ultimate verification of U. This makes a negative answer less likely. The difference in tendency to answer negatively in the two cases affects the results of the truth-condition questionnaires.

Those who look for conditions of ultimate verification in some senses of that expression also seem to look for conditions of absolute or perfect cer-

tainty—in some senses of those terms. Thus, the highly important phrase «identity of conditions of truth» may be said to be sometimes interpreted in directions indicated by the expressions «identity of conditions of ultimate verification» and «identity of conditions of absolute certainty».

It may be asked, Do not the respondents interpret «T is true» in such a way that it means the same as «T»?⁹ To this, one might answer, Means the same as what? Somehow, the respondents would not tend to identify «T is true» with «T» without the explicit or implicit assumption that T when it occurs alone is asserted in some sense of this highly important word.

One might accordingly adopt the following version of the truth-condition questionnaire: «Can you imagine conditions under which you would assert T and not U, or vice versa?»

Such a wording works well to a degree, but the attention is focused on what might be meant by «assert». That term admits various interpretations, and respondents are led into the difficult question of differences between justifiable and nonjustifiable assertions. From there, the questions of verification and certainty are reached. Thus, the version using the term «assert» does not solve many of the difficulties of the other versions.

Several difficulties center on the expression «conceivable» or «imaginable» conditions.

If two sentences are declared synonymous for a person provided he cannot imagine this or that, one may ask how we can separate tests of imagination from tests of sameness of meaning. It might turn out that we find a high positive correlation between resources of imagination and a tendency to find heteronymities. If we, on the other hand, declare two sentences to be synonymous for a person provided there are («in reality») no noncontradictory conditions under which that person would accept the one as true and the other as false, there is need for an additional declaration in order to make a concept applicable: What is meant by «there are no conditions such that ---»? Who is going to judge? What do we know about another person's reactions under any conceivable conditions?

One may give good answers to these questions, but they are likely to involve complexities that we find justifiable not to enter into here.

The synonymity questions of Qs1, Qs2, and Qs3 are open to even more ambiguities than the truth-condition questions. The latter represent an important step in the direction of definite concepts.

VII. INTRODUCTION OF A GROUP OF CONCEPTS

VII.9. Cognitive-Weight-Condition Concepts of Synonymy

Instead of asking a person to imagine conditions under which he would accept a sentence, T , as true, one may write a list of attributes and ask the same question in relation to each item of the list. One may, for example, include the expressions «true», «highly probable», «strongly confirmed», «proved», «perfectly certain», «false», «highly improbable», «strongly disconfirmed», «disproved», and «perfectly uncertain».

Because the items on such lists, as we have used them so far, have certain vague characteristics in common, we have labeled the items «cognitive-weight expressions». We shall not here try to justify such a name. What seems important is that respondents who answer questions about truth or certainty tend to use those expressions in their arguments for or against an opinion and in reformulations of the questions about truth or certainty. By asking them to respond to cognitive-weight-list questionnaires, we obtain important information about attitudes toward the crucial sentences T and U . The truth-condition questionnaires can be conceived as cognitive-weight-condition questionnaires with only one item on the cognitive-weight list.

Just as in the case of the truth-condition questionnaires, a terminology may be introduced, according to which there is synonymy if the cognitive weight of the one sentence is always the same as that of the other, whatever the conditions imagined. Thus, we may form normative definitions of the following kind:

« T and U mean the same for P in S » shall mean the same as « P in S cannot imagine any conditions under which, for the list L , he would attribute a cognitive weight, W_i , to one of the formulations, but not to the other, and at least one of the weights is attributed to one of the formulations».

VII.10. Argumentational Synonymy

The comparison of truth conditions in relation to two sentences may be regarded as part of a much broader comparison, that of argumentational status. Two sentences will be said to have the same «argumentational status» in reference to a group of sentences if it holds good, for each member T_i of that group, that each member is a pro-argument, or a contra-argument, or irrele-

vant in relation to T_i . «Sameness of cognitive meaning» might then be introduced as another name for sameness of argumentational status. Questionnaires based on this vaguely formulated idea are impossible to answer without previous training in *pro et contra dicere*. Even when such training has been given, the questionnaires are difficult to answer. Here is one version:

Qs7. No. ---.

Imagine that you have found two texts, and that you know the author of the one has had no knowledge of the other author or of his text.

Text 1: --- T ---.

Text 2: --- U ---.

We are interested in just how you interpret T and U.

Questions:

Do you interpret T and U in such a way that

1. any argument you would consider to be a pro-argument in relation to T, you would also consider to be a pro-argument in relation to U?
2. If your answer to question 1 is positive, would you consider the strength of each pro-argument in relation to T equal to the strength of that argument in relation to U?
3. [similar to question 1 but concerning contra-arguments]
4. [similar to question 2 but concerning contra-arguments]

Just as in Qs4, we here resort to the respondent's imagination in a rather sweeping way: he is required to imagine arguments for or against T and U. The imagination may be helped by previous answers to Qs8, in which a list of possible arguments, prepared by the analyst, is handed over to the respondent. The list corresponds to the reference lists introduced in investigations of preciseness relations.

Qs8. No. ---.

[identical to Qs7 up to *Questions*, then:]

(A list, L, is handed to the respondent.)

Consider the list, L, containing formulations that possibly would, to you, express arguments for or against T, or for or against U, as you have interpreted T and U. For each item on the list L, we ask you to answer the following questions:

- 1a. Do you consider it, if established, as an argument pro T?
- 1b. Do you consider it, if established, as an argument pro U?
2. If you have answered positively to questions 1a and 1b, would you consider the strength of the pro-argument in relation to T equal to the strength of that argument in relation to U?

VII. INTRODUCTION OF A GROUP OF CONCEPTS

Questions 3a, 3b, and 4 correspond to questions 1a, 1b, and 2, except that they concern contra-arguments.

If answers to 1a, 2a, 3a, and 4a are the same as answers to 1b, 2b, 3b, and 4b, we shall say that for P in S (delimited in relation to the texts), relative to the argumentational reference list L, T and U «have the same argumentational status», or «are Qs8A-synonymous».

VII.11. Løvestad's Questionnaire

Ludvig Løvestad (1945) attempted to construct a strong precization of the expression «the physical law L_1 at the time t_1 was (or is) more testable (or: had a greater or more perfect testability) than the physical law L_2 at time t_2 ». On the basis of the strong precization, he constructed a quantitative measure of testability. This may be viewed as an explication of the expression «more testable than».

To find out to what extent the use of «more testable than» among physicists would correspond to the use of that expression in conformity with his strong precization and his explication, Løvestad constructed a questionnaire of the argumentational kind. He grouped a series of sentences into three classes: first, sentences that, as interpreted by him and if considered to be tenable, would constitute pro-arguments in relation to the sentence «The law of Boyle-Mariotte is more testable now than at the time it was first formulated», this sentence being interpreted in conformity with the precization constructed; second, sentences that would constitute contra-arguments; and third, sentences considered by Løvestad to be irrelevant.

A questionnaire was constructed in which twelve sentences belonging to these classes were listed. Here are the first three:

1. At that time, as well as now, k is conceived as a constant and p and v as the only variables in the law $p v = k$.¹⁰
2. One can today produce greater pressure and volume than at the time of Mariotte, and therefore one can test them over a greater field.
3. Although one could not at the time of Mariotte produce pressures and volumes as great as now, one could at that time, as now, suppose the numerical value of pressure and volume to vary from zero to a value of unlimited greatness, and thus one could at that time suppose the same field of application as now ---.¹¹ (Løvestad 1945: 66ff.; my translation)

Undergraduate, graduate, and postgraduate students were presented with these sentences and invited to answer the following question:

You are going to compare the testability (possibilities of testing) of the law of Boyle-Mariotte, $pV = k$, at the time it was formulated, and the testability today. You are requested to answer in relation to every assertion below, whether you think it can be taken as an argument for or an argument against regarding the law as more testable now than then. (Ibid.)

The interesting results of Løvestad's inquiry cannot be reviewed here. His questionnaire belongs to a kind that has been used for many purposes. It might be conceived as an example of the following skeletal form:

Qs9. No. ---.

Text 1: --- T ---.

Text 2: --- U ---.

The sole difference between these texts consists in the fact that in the second text, U is found at the place in which T is found in the first text.

In the following there is a list of sentences. For each sentence V_1 on this list we ask:

- a1. Does it, as interpreted by you, express an assertion that, if it were tenable, would constitute a pro-argument in relation to T, as you interpret T?
- a2. Does it, as interpreted by you, express an assertion that, if it were tenable, would constitute a pro-argument in relation to U, as you interpret U?
- b1. {like question a1, but substituting «contra-argument» for «pro-argument»}
- b2. {like question a2, with same substitution}
- c1. {like question a1, but substituting «an irrelevant assertion» for pro-argument»}
- c2. {like question a2, with same substitution}

Løvestad's questionnaire does not correspond exactly to this questionnaire because he considered his own precization of «more testable than» in the sentence about the Boyle-Mariotte law to be too complicated to be understood by respondents not proficient in methodology and symbolic logic. Consequently, he had to compare his own answers to a questionnaire of the kind Qs9 with the other respondent's answer to a questionnaire in which

VII. INTRODUCTION OF A GROUP OF CONCEPTS

only one text was offered, containing only the simple expression «more testable than» in the crucial sentence T.

The codification of the results of a questionnaire such as Qs9 is rather complicated. Among other things, one has to consider the following factors:

1. Differences in interpretation of the argument formulations among respondents, and between respondents and the analyst.
2. Differences in the auxiliary hypotheses needed to construct inference links between an argument and the crucial sentences. (Even if the crucial sentences T and U and an argument formulation V_1 are interpreted in the same way by two persons, there are plenty of reasons that their assessment of the argumentational relation between V_1 and T and U might differ.)
3. Differences in results based on one class of argument formulations and results based on a second reference class, the crucial formulations being the same. (Such differences justify a rather skeptical attitude toward attempts to generalize about the relation between T and U on the basis of a single questionnaire.)

VII.12. Recapitulation

In the foregoing sections, a number of ways of asking people about the relations between interpretations of expressions have been described. They have, in part, emerged as a product of discussions that have taken a similar course: they have developed into discussions about cognitive meanings of certain phrases, and it having been found unnecessary for the purposes of discussion to speak about cognitive meanings in general, the discussions have revolved around classifications of sameness of meaning. The participants in these discussions have been scientists, logicians, and philosophers.

Efforts to standardize certain important features of such discussions have led to the construction of questionnaires, samples of which have been introduced in a systematic way in the foregoing. Some are extremely simple and, for the purposes of studying usage, extremely naive. Nevertheless, at least among certain persons considered highly competent, the direct question

«Does «a» in your terminology mean the same as «b»?» is useful, and answers may continue to be relied on as symptomatic of existing usages. One may in discussions with those persons interchange occurrences of «a» with occurrences of «b» without disturbance in the argumentational system.

Other questionnaires are more sophisticated and more adapted to concepts of synonymy likely to be proposed by students of language. They are, on the other hand, extremely complicated to administer. The complexity will, in practice, have the effect that even if the information they yield is considered important, they will rarely be carried out as proposed in this chapter.

This does not mean, however, that they are unfruitful as a basis for the introduction of concepts or tests of synonymy. A highly technical, laborious spectrographical method of testing the assertion «In this container there is iron and only iron» may be used for the introduction of a fruitful concept of iron, even if those using the concept very seldom resort to the laborious techniques of subsumption. The standard techniques delimit the *claims* of those who speak about iron and use the concept. Only now and then, but in highly important situations from the point of view of research, is the laborious, complete test performed. Nevertheless, the whole conceptual structure of the sciences in question is dependent on the existence of such tests as a kind of supreme court in matters of terminology.

Thus, in cases of major disagreement among those who make hypotheses about sameness of meaning, the more complicated concepts proposed in the foregoing furnish tests that the analysts who disagree can accept as a basis of decision.

By interpreting synonymy sentences—in the terminology of chapter 1—in terms of the questionnaire concept ‘Qsxy-synonymy’, we relate a set of assertions to each sentence. On the basis of knowledge about the authors of such sentences, we venture to assert that their intended meanings are quite similar to those created by using certain Qsxy-concepts. The vast majority of synonymy sentences are, however, produced by authors who have hardly intended anything very similar to the questionnaire concepts. Such concepts may not be reached even by transintentional precization of the synonymy sentences. The Qsxy-synonymy concepts are, rather, explications (in the terminology of chapter 2).

If existing synonymy sentences are interpreted *as if* they were meant

VII. INTRODUCTION OF A GROUP OF CONCEPTS

to express assertions about Qsxy-synonymity of some kind, hypotheses are framed that are of interest and are testable.

Of greater import, however, is the aim of creating a suitable terminology for *future* use. The synonymity concepts introduced are thought to be of use in such future investigations. They are considered to represent fruitful classifications of phenomena. If a synonymity relation in the sense of one of the concepts is found, this should be a fairly reliable symptom of many other relations that contribute to our understanding of terminological and, indirectly, nonterminological phenomena. One field of phenomena is that of controversies in general and various specific kinds of disagreements (cf. chapter 3). In a discussion—learned or popular—knowledge about how the participants would answer the questionnaires greatly increases our information relevant to hypotheses about the extent and kinds of disagreement. Such knowledge renders it possible to make better predictions about the future course of the discussion and to explain better the development of the discussion in the past.

There are many obvious limitations to the applicability of the questionnaires. The questionnaire respondents must be willing to answer, and to answer honestly. Even if willing to do so, they may be more or less incapable of carrying out the task. Further, it seems rather difficult to formulate synonymity questions that are understandable and precise.

The questionnaires have not, however, been introduced in anticipation of unlimited applicability. They have been introduced because they are considered sufficiently useful at the present stage of research to be tried out.

B. Concepts of Interpersonal Synonymity

VII.13. Interpersonal Synonymity Hypotheses Based on Information About Intrapersonal Synonymity

All the introduced synonymity tests or concepts refer to usage by a single person. The standard sentence used in the reports based on the questionnaires is ««a» and «b» are Qsx-synonymous for *P* in *S*».

If we try to use the reports as evidence of opinions held by the respondent concerning the questions intended by the analyst, interpersonal syn-

onymity is involved. Thus, the statement that for P «a» and «b» are QsxB-synonymous involves hypotheses that the respondent interprets (or does not interpret) the synonymity question as the analyst wishes it to be interpreted. In practice, such hypotheses have been submitted to testing by extensive interviewing of the respondents. In certain cases it is thought that one can, with a high degree of certainty, establish that the respondents did not interpret the questionnaire as did the analyst. On the other hand, it is difficult to establish with a high degree of certainty that a respondent did interpret it as intended by the analyst. There is need for systematic procedures by which assertions about interpersonal synonymity can be connected with research, and not merely with guesses and intuitions.

Let us consider the formulation ««a» for p in s is synonymous with «a» for q in s». Small letters, p, q, for persons are used because of the formulas and the number of repetitions required in this and the following sections.

In symbols:

$$\text{Syn}(a\ p\ s, a\ q\ s) \text{ or } \neg\text{Het}(a\ p\ s, a\ q\ s)$$

As regards s, we postulate that a text is present to p and q, and that «a» is a part of the text.

If we can construct a satisfactory concept, or a class of such concepts, adapted to the above symbolized assertion, it is relatively easy to proceed to the more complex general case:

$$\text{Syn}(a_1\ P_1\ s_1, a_2\ P_2\ s_2)$$

In this chapter we can only introduce certain concepts and show their close relation to previously introduced ones. We shall add some words of motivation; but we cannot here confirm the fruitfulness of the introduced concepts. That would require description of applications to concrete cases, a task demanding considerable space. In dealing with applications, we shall come back to the question of fruitfulness.

Roughly speaking, the concepts of interpersonal synonymity to be introduced will be closely adapted to one of the usual ways in which we, in scientific discourse, try to make others understand what we mean by a sentence. Probably we find out what we ourselves mean by a sentence in a sim-

VII. INTRODUCTION OF A GROUP OF CONCEPTS

ilar way, only we condense our questions to ourselves in such a way that they are scarcely, if at all, articulated. The answers are likewise in a contracted form, as when people speak to themselves.

There is, as previously mentioned, no reason to believe that we have any methods for discovering our own usage other than those we use when investigating usage by others. We have, however, a much more extended and reliable knowledge of our own speech habits than we do of other people's habits—at least we are apt to believe so.

To find out one's own usage, it is convenient to treat oneself as another person. This has been done in psychology, for example, by Ebbinghaus. It is possible to extend the following account of interpersonal synonymy to intrapersonal synonymy, taking intrapersonal relations as a unique special case of interpersonal relations.

Suppose the text is the introductory treatise on theoretical mechanics by A. E. H. Love (1897), and that the formulation, «a», to be discussed is «Every body, and every individual part of a body, has a constant mass, and the mass of the body is the sum of the masses of its parts». Let us suppose that two readers, p and q, are physicists, and that they, upon reading the formulation «a» within the time interval t, agree to make an attempt to find out whether, or to what degree, they understood «a» in the same way within the time interval t. We suppose that during t they established a hypothesis of interpretation. Explicitly or implicitly, we suppose that they thought they understood what Love intended by the formulation «a».¹²

One of the ways in which p and q tend to explore each other's interpretations consists in their expressing what they understood by «a» in other words. They reformulate «a» and say, «I understood b by «a». Did you do that, or did you interpret «a» otherwise?» In «b», they have, for example, replaced the word «mass» with some definiens of «mass» (or more correctly formulated, «with a definiens expression in some normative definition of «mass»»). Then, they might replace the definiens of the definition of «mass» with an expression in which some terms of the definiens are replaced with some definientia of definitions of those terms. Thus, they might discuss how they interpret Love's introduction of 'mass': If we associate the number 1 with any particular material body A, then we can associate a definite positive number m with any other material body B, this number is the mass-ratio of the two bodies A and B. We call it «the mass of B»

(Love 1897: 87). When they use this text to construct a definiens formulation of «mass», their interpretation of the formulation will depend very much on their interpretation of the expressions «mass-ratio» and «material body». Both are explicitly defined by Love, and the investigation of interpretations of «a» naturally leads to the definiens formulations of those expressions, and so forth.

Maybe p would have understood by «b» the same as he understood by «a», within t, if the text had contained a strong popularization of «a». If p says to q that he by «a» understands the same as by «b», and q answers that he does not, this difference may more naturally be attributed to ambiguities of the popularization than to different interpretations of «a». Thus, in replacing «a» with other formulations, p and q ought not to replace it with just any synonymous formulations, arbitrarily selected—but which synonymities should be selected is the great question. In general, we may say that p and q should try to substitute for «a» sentences that there is no reason to believe are understood by p and q in still more different ways than is «a» itself. Further, the substituted formulations ought to be apt to disclose possible differences of interpretation of «a». In other words, a partial synonym «b» ought to be more (interpersonally) precise than «a» within the group of persons p and q and in the situation at hand. Let us suppose that p reflects, «How can «a» be interpreted otherwise than I did? I now see that there is a difference that might be relevant, but how shall I be able to tell q about this difference of interpretation I now conceive as possible? Perhaps I can do so by formulating «a» in the following way: I will ask if q by «a» means b and not c, or c and not b. This might prove helpful because «b» and «c» are very explicit in turning the attention to the difference d, and I have no particular reason to suspect that «b» and «c» are interpreted by q in such a way as to extinguish the difference d from his view». This last reflection is of great importance to the transition from intrapersonal to interpersonal preciseness.

Briefly, p ought to select precisizations of «a» that are apt to disclose possible differences in interpretation of «a», in that they permit only some of the interpretations that «a» permits. Asking q whether he thinks «a» is synonymous with these formulations, p may hope that in the case of q's answering positively in relation to a formulation «b» and negatively to a formulation «c», *the difference in meaning between these two formulations will be*

VII. INTRODUCTION OF A GROUP OF CONCEPTS

approximately the same for q as for p. He cannot be sure of this approximate identity, but he may from general considerations of the similarity of their education and training, or other similarities, have reason to suppose that «b» and «c» are able to disclose the difference intended by p, or one closely similar.

This procedure of reformulation does not lead to anything else than the establishment of *two maps of synonymy and heteronymy relations*, one map showing relations within the usage of p, and the other showing relations within the usage of q.

((31)) If there is a one-to-one correspondence of points on two intrapersonal synonymy maps, and the points are selected with due consideration of relations of preciseness and ambiguity *within each map*, we shall say that there is *maximum confirmation of interpersonal synonymy* of «a» in relation to p and q in s, and in relation to the reference class of formulations defined by the maps, that is, by the reformulations used.

When we compare two maximum confirmations, the one in relation to a reference class that is part of the other class, that confirmation will by definition be called the stronger that is maximal in relation to the most comprehensive reference class most comprehensively tested.

Strictly speaking, we ought not to say that by the foregoing definition, the formulation «Syn(a p s, a q s) holds good in relation to R, where R is the total reference class used» is operationally defined. We ought primarily to announce the operational character of the formulation «Syn(a p s, a q s) is maximally confirmed in relation to R».

The difference is of considerable interest, being associated with the general problem of semantical relations between «/-a» and «/-a has the positive cognitive weight of the class W», where «/-» is a sign of asserting, and W is a class of weight expressions obtained by studying use of the term «assert».

We do think it justifiable to use the first formulation as synonymous with the latter, but we acknowledge that in other fields of discussion, it is fruitful to make a distinction between them.

The introduced concept of interpersonal synonymy may be said to be equivalent to a concept of identical structure of intrapersonal synonymy

and heteronymity relations within a system of formulations making up highly qualified reference classes of the formulation investigated. This is, vaguely speaking, in agreement with tendencies to define intersubjective characteristics of scientific knowledge by means of identity of structure of systems.

VII.14. Systematic Exposition of a Procedure

The procedure to be described may be subjected to variation and may be carried out with various degrees of elaborateness. Some of the variations owing to differences of order and elaborateness are important enough to justify talking about different concepts. We shall here describe only one possibility without claiming that the details may not with profit be modified extensively.

The successive steps in the procedure are labeled A, B, C, etc., to make a survey easier.

A. *Preliminary Lists of Interpretations*

The person *p* makes a preliminary list of interpretations of «*a*». The list consists of statements, about each of which he guesses or infers from previous investigations that it expresses an assertion *q* could possibly find expressed by «*a*» in *s*.

The list, let us call it the «preliminary list of interpretations according to *p*», must be a heteronymous class according to *p*'s usage; no member must be such that any other member is a synonymic alternative of it for *p* in *s* (see chapter I, section 10).

An analogous list is made by *q*.

B. *Ordinary, First-Order Reference Class*

If «*b*» is a member of the preliminary *p*-list, this means that in *the way p interprets* «*b*», «*b*» expresses an assertion that *p* guesses *q* might find expressed by «*a*». Even if this should be the case, however, it is not certain that «*b*», as interpreted by *q*, expresses that assertion. That is, nothing guarantees that «*b*» for *p* in *s* is interpersonally synonymous with «*b*» for *q* in *s*.

If *p* has reason to believe, or guesses, that «*c*» would express to *q* what «*b*» expresses to *p*, he should substitute «*c*» for «*b*» in the *p*-list.

VII. INTRODUCTION OF A GROUP OF CONCEPTS

Similar changes ought to be made in q's preliminary list.

The resulting lists are then adapted to the other person in two ways:

1. Only such formulations are included that one of the persons guesses the other person might find to be synonymous with «a».
2. The formulations selected are reformulated if one of the persons has gathered evidence showing that what is to him expressed by the formulation adopted in the list is less likely to be thus interpreted than a certain other formulation. The latter is in that case included in the list, and the former is dropped.

Let us call the corrected lists (or the preliminary lists if it is found that no formulation ought to be changed on the basis of existing evidence) «the ordinary (first-order) p-class and q-class of reference».

C. Hypotheses of Interpersonal Synonymy, Defined on the Basis of Synonymy Agreements in Relation to the Ordinary, First-Order Reference Class

In relation to each member of the first-order p-class, q is presented with a synonymy questionnaire or a battery of such questionnaires. It is immaterial here which Qsx-concepts are used. For the sake of simplicity, let us suppose that QsI is used. Accordingly, q is simply asked whether «a» in s is for him (intrapersonally) synonymous with the list member at issue.

If the members of the reference class consisting of the p- and the q-class are called $a, \dots, a_1, \dots, a_n$, it is, by use of QsI, established which of the following four relations hold good.

- (1) $\text{Syn}(a a_i p s) \ \& \ \text{Syn}(a a_i q s)$
- (2) $\neg \text{Syn}(a a_i p s) \ \& \ \neg \text{Syn}(a a_i q s)$

«Syn» is in the formulas an abbreviation for «SynQsIA».

A case of (1) or (2) is called a synonymy agreement between p and q and is counted as a confirmatory instance of $\text{Syn}(a p s, a q s)$.

Each case of synonymy disagreement

- (3) $\text{Syn}(a a_i p s) \ \& \ \neg \text{Syn}(a a_i q s)$
- (4) $\neg \text{Syn}(a a_i p s) \ \& \ \text{Syn}(a a_i q s)$

is counted as a disconfirmatory instance of $\text{Syn}(a \text{ p } s, a \text{ q } s)$.

Suppose there are N agreements and M disagreements. The fraction

$$((32)) \quad \frac{N}{N + M}$$

will be taken as a measure of the degree to which $\text{Syn}(a \text{ p } s, a \text{ q } s)$ is confirmed in relation to the reference class R . If the respondents p and q give unqualified positive or negative answers to the Q_{s1} questionnaire, we shall have $N + M = n$.

If there is no synonymy disagreement between p and q in s as regards « a » in relation to R , we shall say that the hypothesis of interpersonal synonymy of « a » for p in s and « a » for q in s is confirmed with maximal strength in relation to the first-order reference class R . In that case we have

$$\frac{N}{N + M} = 1$$

Note 1: for the sake of simplicity we shall in the following assume that respondents always give unqualified answers. As a matter of fact, there tend to be a significant number of nonstraight answers, which complicates quantitative treatment.

Note 2: We do not do so here, but it might be fruitful to make an additional reference class of formulations not fulfilling the definitional characteristics of the p - and q -lists. The formulations in that list would, in other words, be such that each person thinks it not practically possible that the other person would interpret « a » as synonymous with it. However, p and q may «think» erroneously.

The value of the p - and q -lists as reference classes depends on whether the list members have small internal distances of meaning. If they are not synonymous for p or q in s , they should not be very far from each other in meaning. These assumptions are made on the basis of similarities among the semantical systems of people within the same language community, and similarity (however slight) between the use of one and the same formulation in different situations.

The advantage of relatively close relations of meaning within the reference class may also be based on the fact that comparatively small differences

VII. INTRODUCTION OF A GROUP OF CONCEPTS

between what p intends and what q intends by «a» in s would be more easily discovered, if they exist.

There might, however, be formulations outside any p- or q-list that would give us valuable hints; therefore, a broader list should occasionally be used as a check.

VII.15. Interlude

I can now imagine an impatient reader saying:

I recognize the value of schematical descriptions of concrete procedures. They connect the beautiful but airy castles of free thought with the dirt and sweat of earth. Do you really think, though, that you correctly grasped the nature of interpersonal synonymity in the last section?

Let us suppose you used the procedure described in the last section and that you got nonmaximal confirmation. It is not possible that you would nevertheless exclaim: This is just a matter of intricate terminology. I am sure the other person interpreted «a» just as I did. Or, after a maximal confirmation: This is very misleading. I am sure that he did not interpret «a» just as I did, despite these results!

We have a kind of intuitive knowledge of what is meant by saying that two persons mean the same by a sentence. «Synonymity» has an intuitive sense, just as «simultaneity» has. When you select your technical concepts, you use intuition as a guide. However, they are apt to make inessentials appear essential. External and arbitrary matters dominate the description of procedure.

Why not simply say that the procedures described, if certain results are obtained, strengthen the reasons for believing that interpersonal synonymity really exists between p and q as regards «a»? By defining synonymity by means of exhaustive procedures, you miss the thing itself, at least its most important aspects, namely, the properties intuitively known but not formulated.

I can only answer my impatient reader as follows: You do not seem to have had the depressing experience of obtaining pseudoagreements and pseudodisagreements caused by misleading intuitive hunches regarding distinctions of meaning. If you are not seriously convinced of the basic shortcomings of our intuitive use of language, for at least some purposes that you are deeply interested in, there can be no motive for you to continue reading this work. Intuitively, we may associate very many things of interest with terms such as «simultaneity», «intelligence», and «synonymity»,

but even if we associated the same things, so that an interpersonal relation was established, it cannot be the aim of concept formation somehow to cover all those associations in one concept.

The feeling that we, as we say, «know what we mean» and what others mean does not rule out the possibility that two minutes later we shall have to confess ourselves unable to find out even intuitively what we «knew» two minutes ago. It does not rule out grave deficiency of depth of intention. Let us take a famous example, that of the word «simultaneous». I have a very convincing feeling of what it means that two events are simultaneous: it means they happen at the same time. Moreover, I have the feeling I can «see» what is meant by that. Nevertheless, there are fields of discussion of considerable interest to some people in which «simultaneous» is defined by intricate procedures involving velocities of bodies and many other properties. These are inessential or even irrelevant to my intuition of the meaning of «simultaneity». The procedures leave out what may seem to be the very simple thing itself, the being at the same time. As a matter of fact, though, in every science, in every description that aims at a certain degree of accuracy and intersubjectivity, there goes on a continual process of emancipation from intuitive hunches insofar—*but only insofar*—as they have proved to be misleading. Complete emancipation would lead to nonsense. Probably no one acquainted with discussions on «the» meaning of «meaning», on the meaning of certain texts, and on a host of other questions involving communication, would deny that *conflicting* intuitions are appealed to by different persons, and that the intuitive answers often are answers based on no reflection, no critical scrutiny of the issues involved.

If I felt certain that somebody used «a» in the same sense as myself in spite of a strong disconfirmation arrived at by the procedures described, I would not trust the feeling without certain reservations. Its appearance would be a symptom that there are ways of using the expression «interpersonal synonymity» that would, if they were made precise, lead to other concepts than the one introduced here. Maybe some of them would be rather fruitful concepts. The feeling would constitute a valuable motive for improving the introduced concepts, or at least for changing the names of the concepts so that they would not give misleading associations.

If the procedures were not used to define concepts but to establish symptoms that certain relations fall under a concept intuitively known,

VII. INTRODUCTION OF A GROUP OF CONCEPTS

this would lead to perplexities as soon as somebody said, « Your operation gives less reliable symptoms than mine» or «Your operations do not really furnish symptoms of interpersonal synonymity, but only of something similar». Who is to determine just what *is* interpersonal synonymity as intuitively known? There is nothing *definite* to be found. Compare the discussions about whether this or that concept of intelligence measures so-called «real intelligence» or only furnishes symptoms of it, or even symptoms of something alien to real intelligence.

The discussion might be fruitful if the word «intelligence» as used in everyday life were precized in different directions so that one could say, for example, «The concept P45 of some psychologists is very similar to the concept Q48 arrived by the precizing «intelligence» in direction number 7, whereas the concept P49 is not. There is a very high correlation between people subsumable under concept Q53 and those falling under P59». On the basis of such findings, some concepts would probably no longer be named «intelligence», because this would be misleading for people who are not apt to use definitions but prefer to rely on associations connected with the conceptual designation, however misleading.

What is more embarrassing than lack of correspondence with previous vague and ambiguous usage is the vast number of different concepts, all of which seem to be nearly equal as regards fruitfulness for the same purposes. How are we to decide which ones to use as a conceptual basis? In physics it has been possible to work out a very small number of concepts that suffice to formulate in a few words a great many laws and correlations. As we approach the more complex finds of investigation—for example, economics, social psychology, language behavior—there seems to be no hope of systematizing large masses of knowledge on the basis of a few simple concepts. This may lead us to give up attempting to work with relatively precise linguistic tools—we shall then continue to rely on words with such a vast and vague multitude of meanings that they give a superficial impression of being able to bring together very different phenomena into useful classifications (consider «group», «propaganda», «learning», «demand», etc.). The alternative is to try to work with a large number of more or less complex concepts, hoping that someday it will be possible to undertake a reduction in their number and complexity.

I look forward—and not without impatience—to an account of em-

pirical work, which will make it possible to evaluate the fruitfulness of the concepts introduced in this work. Until that happens, there is not much to say for or against the concepts.

With this digression over, we may return to our topic.

VII.16. Systematic Exposition Continued

In the definition of section 14, each intrapersonal synonymy agreement

$$\text{Syn}(a_i p s) \& \text{Syn}(a_i q s) \text{ or } \neg \text{Syn}(a_i p s) \& \neg \text{Syn}(a_i q s)$$

and each synonymy disagreement count equally. They are simply added up as of equal importance.

In our search for more refined procedures, we may begin with certain modifications of the reference class R.

Suppose we find that

$$\neg \text{Syn}(a_i p s) \& \text{Syn}(a_i q s)$$

and suppose that p makes a list of heteronymous interpretations $a_{11}, a_{12}, \dots, a_{1j}, \dots$ of a_1 . Maybe a response by means of the questionnaire QSI shows that

$$(j): \text{Syn}(a_1 a_{1j} p s) \supset \neg \text{Syn}(a_1 a_{1j} q s) \& \neg \text{Syn}(a_1 a_{1j} p s) \supset \text{Syn}(a_1 a_{1j} q s)$$

This means that there is maximal disagreement regarding what is meant by the formulation a_1 of R. In scientific debate this probably would disqualify a_1 as a tool for elucidation of possible differences in p's and q's usage of «a».

Suppose that p, on the basis of the discouraging results reported above, eliminates a_1 and takes up $a_{11}, a_{12}, \dots, a_{1j}, \dots$ instead. Maybe he finds:

$$(j): \text{Syn}(a_1 a_{1j} p s) \supset \neg \text{Syn}(a_1 a_{1j} q s) \& \neg \text{Syn}(a_1 a_{1j} p s) \supset \text{Syn}(a_1 a_{1j} q s)$$

for example, maximal synonymy agreement in relation to the additional reference class.

VII. INTRODUCTION OF A GROUP OF CONCEPTS

In scientific discussion this result would probably be regarded as a much stronger confirmation of interpersonal synonymy than the strength of disconfirmation attributed to the initial result

$$-\text{Syn}(a_i p s) \& \text{Syn}(a_i p s)$$

We propose to construct concepts in accordance with this evaluation, which is implicit in scientific procedures.

Let us call R a «reference class of the first order», that is, a reference class whose members are not themselves made subject of controls involving reference classes.

((33)) The argumentative power of a member a_i of R in a discussion of the strength of confirmation attributable to a synonymy agreement

$$\text{Syn}(a_i p s) \& \text{Syn}(a_i q s) \text{ or } -\text{Syn}(a_i p s) \& -\text{Syn}(a_i q s)$$

or the strength of disconfirmation attributable to a synonymy disagreement

$$\text{Syn}(a_i p s) \& -\text{Syn}(a_i q s)$$

or

$$-\text{Syn}(a_i p s) \& \text{Syn}(a_i q s)$$

depends on the strength of confirmation obtainable as regards the interpersonal synonymy hypothesis

$$\text{Syn}(a_i p s, a_i q s)$$

((34)) Therefore, we propose that the initial hypothesis

$$\text{Syn}(a p s, a q s)$$

is by definition to be regarded as more strongly confirmed than the maximal confirmation obtained by a relation to R if the interpersonal synonymy of at least one member, a_i (of R), is maximally confirmed in relation to a reference class R_i , which is constructed in the same way as R .

((35)) If maximal confirmation of interpersonal synonymy is obtained in relation to all second-order reference classes, we shall

say that the conclusion as regards degree of confirmation of interpersonal synonymy in relation to R is maximally confirmed in relation to a complete system of second-order reference classes.

If, however, the use of second-order reference classes leads to cases of synonymy disagreement, this should be made the basis for changing R.

If the supposed interpersonal synonymy of a member a_i of the first-order reference class is strongly disconfirmed in relation to a second-order reference class R_i , it should be eliminated from R.¹³ Any deviation from

$$\frac{N}{N + M} = 1$$

is a serious matter, but does not necessarily destroy the value of a_i as an indicator.

If every instance of disconfirmation were to result in elimination, we should have to investigate the members of R_i in turn. Any confirmation of interpersonal synonymy of a member a_{ij} of R_i in relation to a third-order reference class ought in that case to be regarded as a justification for eliminating a_{ij} from R_i , which in turn would reestablish R as a workable reference class. Thus, the rigorous rule of eliminating any member of a reference class, provided at least one instance of synonymy disagreement appears, would result in a laborious chain of investigations of higher-order reference classes—a chain so long, perhaps, as to make it practically impossible, and quite unfruitful, to use the procedure described.

If a member a_{ij} of R is eliminated on the basis of strong disconfirmation of its interpersonal synonymy for p and q, the question arises of whether any, or perhaps all, of the corresponding members, a_{ij} , of the second-order reference class R_i should be included in R. If they should, this requires construction of a new reference class R'.

If evidence is available as to why such a member should not be included, it ought not to be included. The formulations a_{ij} are apt to be precisizations or near-precisizations in relation to a_i , and should therefore furnish valuable reference material.

The numerical value $\frac{N}{N + M}$ found in relation to R' may be very different from that found in relation to R. Theoretically, it is possible that it could change from 1 to 0 or from 0 to 1.

VII. INTRODUCTION OF A GROUP OF CONCEPTS

The greater the difference, the more reason there is to continue the process of testing $\text{Syn}(a p s, a q s)$, either by constructing higher-order reference classes or by simply adding members to the already constructed classes on the basis of guesswork or inferences of some sort.

((36)) In comparisons of the different numerical values $\frac{N}{N+M}$ obtained, that one is to be regarded as the most reliable indicator of which value, if any, would be found if the process of testing continued indefinitely, which is based on the most comprehensive classes, and where the test is continued to the highest order of reference classes.

The rule does not apply to the cases most frequently encountered in practice, namely that one test is superior in some respects—for example, in having some very comprehensive reference classes—whereas another test is superior with respect to higher-order classes.

It would be theoretically interesting, but scarcely useful in practice, to define « $\text{Syn}(a p s, a q s)$ » as the relation between $a p q$ and s holding good in the case that $\frac{N}{N+M}$ tends toward 1 with increase in comprehensiveness of reference classes of any order and with increase in the ordinal number of the highest-order class.

Let us use the symbol $/r/$ to represent the number of members of a reference class r , and by $/v/$ symbolize the ordinal number of the order of the higher-order r . We may introduce a concept 'degree of interpersonal synonymy', DS , in the following way:

$$((37)) \quad DS = \lim_{\substack{N \rightarrow \infty \\ M \rightarrow \infty}} \frac{N}{N+M} \quad \begin{matrix} /r/ \rightarrow \infty \\ /v/ \rightarrow \infty \end{matrix}$$

It is not our purpose to maintain that this quantitative concept is fruitful, and we shall therefore leave undiscussed the many practical and theoretical difficulties we should meet if we tried to apply it. We mention the context because fruitful quantitative concepts can be worked out with ((37)) as a convenient starting point.

((38)) In the following, sentences of the kind «If $\text{Syn}(a p s, a q s)$ ---, then ---» may be conceived as shorthand for «If $\text{Syn}(a p s, a q s)$ is

confirmed with maximum strength in relation to a reference class R, then ---».

Very often, we shall deal with relations in which this usage is convenient. In other cases, we shall write in full, for example, «If Syn(a p s, a q s) is confirmed by means of the following tests --- and to the following degree ---, then ---».

In section 14 we described under the headings A, B, and C three steps in the procedure of establishing hypotheses of interpersonal synonymy. We shall now continue the condensed description, which at the same time is part of the definition of «interpersonal synonymy» as the term is used in this work.

D. Preliminary Second-Order Lists of Interpretation

For each member of the ordinary, first-order reference class, p and q construct lists of interpretation of the same kind as described under heading VII.14, A.

E. Ordinary, Second-Order Reference Classes

For each member of the first-order reference class, an ordinary reference class is constructed in accordance with the rules laid down under heading B.

F. Hypotheses of Interpersonal Synonymy of Each Member of the Ordinary, First-Order Reference Class

Hypotheses of interpersonal synonymy are established in accordance with the procedure indicated under heading C.

G. New, First-Order Reference Class Checked by the Second-Order Reference Classes Described Under D–E

Members of the ordinary, first-order reference class that are disqualified by occurrence of synonymy disagreements listed under F, are dropped. The rest of the members of the ordinary, first-order reference class are replaced by their corresponding second-order reference classes.

The resultant total reference class will be called «a first-order reference class tested by second-order reference classes».

VII. INTRODUCTION OF A GROUP OF CONCEPTS

H. Hypothesis of Interpersonal Synonymy, Defined on the Basis of Synonymy Agreements in Relation to the First-Order Reference Class Tested by Second-Order Classes

Step H and the following steps correspond to step D and onward.

From step 1 on, there will be no step that involves new procedures. In principle, the process can be continued indefinitely. At each step corresponding to H, a new hypotheses is constructed, which is based on more comprehensive material than the foregoing hypothesis. Each hypothesis is operationally defined by the steps leading up to it.

The most general case of interpersonal synonymy

$$(1) \text{Syn}(a_1 p_1 s_1, a_2 p_2 s_2)$$

where

$$-\text{Id}(a_1 a_2) \ \& \ -\text{Id}(p_1 p_2) \ \& \ -\text{Id}(s_1 s_2)$$

may be defined by means of the procedures described above. It is, however, convenient to try to reduce the general case to the special case already discussed.

If

$$(2) \text{Syn}(a_1 p_1 s_1, a_2 p_1 s_2) \text{ or } \text{Syn}(a_2 p_2 s_2, a_1 p_2 s_1)$$

then (1) may be reduced to the special case:

$$\text{Syn}(a_2 p_1 s_2, a_2 p_2 s_2) \text{ or } \text{Syn}(a_1 p_1 s_1, a_1 p_2 s_1)$$

If (2) does not hold, but

$$\text{Syn}(a_1 p_1 s_1, a_1 p_1 s_2) \text{ or } \text{Syn}(a_2 p_2 s_2, a_2 p_2 s_1)$$

then we may change (1) into an interpersonal synonymy relation

$$(3) \text{Syn}(a_1 p_1 s_1, a_2 p_2 s_1) \text{ or } \text{Syn}(a_1 p_1 s_2, a_2 p_2 s_2)$$

If (2) does not hold, but

$\text{Syn}(a_1 a_2 p_1 s_1)$ or $\text{Syn}(a_1 a_2 p_2 s_2)$

then we may instead of (1) use an ambiguity hypothesis

(4) $\text{Syn}(a_1 p_1 s_1, a_1 p_2 s_2)$ or $\text{Syn}(a_2 p_1 s_1, a_2 p_2 s_2)$

for example,

$\text{Het}(a_1 p_1 s_1, a_1 p_2 s_2)$ or $\text{Het}(a_2 p_1 s_1, a_2 p_2 s_2)$

The foregoing reductions are convenient, but they do not make any difference as regards procedures for testing the hypotheses.

VII.17. *Interpersonal Relations of Interpretation and Preciseness*

Because interpretation and preciseness are defined here by synonymy, the definitions of interpersonal relations follow from the definitions in sections 14 and 16 together with those regarding interpretation and preciseness in chapter 1.

An established case of interpersonal synonymy between «a» for p in s and «a» for q in s implies an interpersonal relation of interpretation, but the converse does not hold. This is so because the interpretational relation does not say more than that *within* the type of situation s, a synonymy relation holds. If it holds in a definite subclass of situations, and not in every subclass of s, the general relation $\text{Syn}(y a p s, a q s)$ cannot be maintained.

As regards relations of preciseness, we have:

$$\begin{aligned} (5) \text{Pr}(a p s, a q s) = & \supset (\text{Ex}). \text{Synalt}(a x q s) \ \& \ \text{-Synalt}(a x p s) \\ & \& (\text{Ey}). \text{Synalt}(a y p s) \ \& \ \text{-Synalt}(a y q s) \\ & \& (\text{Ez}). \text{Synalt}(a z p s) \end{aligned}$$

This means that to establish interpersonal relations of preciseness, we shall have to work not just with one formulation, but with any formulation that possibly could be shown to be an x, y, or z of the kind satisfying (5).

VII. INTRODUCTION OF A GROUP OF CONCEPTS

The difficulties connected with a survey of that kind lead to the use of the reference-class method of chapter 2, section 4. If the reference class has n members, there will be separate problems of interpersonal synonymy as regards each of the members.

Although testing interpersonal relations of preciseness requires much work, this does not limit use of the concept to those, perhaps very few, cases in which the operations are performed in all their details. We must distinguish between maintaining a synonymy hypothesis as a fruitful working hypothesis, and testing such a hypothesis with the rigor demanded by the procedural definition. The definition delimits our claims, not necessarily our knowledge, and not at all our guesses.

C. Synonymy of Occurrence Analysis

VII.18. «Synonymy» Defined in the Terms of Occurrence Analysis

In the description of connotational occurrence analysis, we left undecided the question of how to interpret the concluding sentences, the hypotheses in the form of (complete) descriptive definitions of expressions subjected to analysis. One of the concluding hypotheses of the Zaslavski analysis is formulated (roughly) as follows: «total democracy» means to Zaslavski the same as «a kind of organization of society by which the possibilities of each member of the community to influence decisions and policies affecting it are maximized». According to the terminological stipulations of occurrence analysis, this Ds-formulation is meant to express an interpersonal synonymy hypothesis. On the one hand, we have Zaslavski represented by his text *La démocratie soviétique*. Taking as our point of departure the extremely complicated texture of usages of the term «democracy» since Aristotle, we are interested in localizing Zaslavski's usage within that texture. To avoid imposing on him a ready-made classificatory system of usages (for example, classification into Eastern and Western usage), we have tried to stick as closely as possible to the only direct source acknowledged in the analysis: the text itself, with its 192 *use* occurrences.

On the other hand, in an interpersonal synonymity investigation, we have the analyst and his intended public. The analyst tries to convey the intended cognitive meaning of «democracy» (supposing as a tentative hypothesis that there is one) in a terminology suitable to himself and his intended public. That is to say, the analyst's interpretation of the definiens expression of the quoted Ds-formulation should, if this formulation is a communicational success, be identical or closely similar to the interpretation that Zaslavski tries to convey to his readers.

This version of the problem situation in occurrence analysis suggests a need to delimit what is claimed when an identity or close similarity of interpretation is asserted. Proposals for such claims are described in this chapter. One may introduce concepts of interpersonal synonymity in connection with standardized questionnaire and interview techniques. By this connection, the large number of intrapersonal synonymity hypotheses (implied in our implicate formulations in the Zaslavski analysis) and the large number of interpersonal synonymity hypotheses (implied or directly formulated in our inferences and concluding descriptive definitions) acquire a status of testable hypotheses.

The case of Zaslavski is a good example of the practical difficulties encountered when we try a direct test in the way suggested by our Qs questionnaires: it is difficult, if not impossible, to get answers from Zaslavski himself.

Such difficulties, coupled with more fundamental considerations, lead us to attempt to delimit tests or concepts that are closely linked with the steps of occurrence analysis itself.

The concepts to be introduced below seem at first to be based on procedures that differ radically from the questionnaire techniques. There is, however, a close connection. If an author is alive, and one is interested in his terminology, questionnaires and interviews can augment the number of use occurrences of the terms at issue. By means of Qs1, the number of metaoccurrences are augmented, but other questionnaires are also adapted to the creation of new use occurrences. Thus, the questionnaire methods are, so to speak, tools by which synthetical or artificial texts—of special interest to occurrence analysis—may be created. As will be seen later, there are also some relations of interest between the occurrence concepts of synonymity and the already introduced concepts or tests.

VII. INTRODUCTION OF A GROUP OF CONCEPTS

VII.19. Introduction of a Concept of 'Occurrence Synonymity'

Let us consider the following text:

(1) «Wenn ein Aprodukt zweier Aahlen $a.b$ durch eine Logare p teilbar ist, so muss wenigstens der eine der Faktoren, a, b durch p teilbar sein.»

Suppose there is no other text from the hand of this text's author, and that the quoted sentence is the only occurrence sentence containing the term «*Logare*».

Suppose under analogous circumstances we find a second text by a second author:

(2) «Wenn ein Brodukt zweier Bahlen $a.b$ durch eine Mogare p teilbar ist, so muss wenigstens der eine der Faktoren a, b durch p teilbar sein.»

Let us further suppose that we wish to give answers to the following questions:

What is the intended cognitive meaning of «*Logare*» (if there is any)?

What is the intended cognitive meaning of «*Mogare*» (if there is any)?

Do «*Logare*» and «*Mogare*» mean the same?

After we have made two lists of implicates, let us suppose that we make the following hypotheses of translations and inferences:

1. «*Aprodukt*» and «*Brodukt*» mean the same as «product» in the terminology of the analyst. «*Aahlen*» and «*Bahlen*» mean the same as «natural number» in the terminology of the analyst.
2. *Eine Logare* is a member of a certain class of numbers (which class it is remains to be found).
3. *Eine Mogare* is a member of a certain class of numbers.

If these three hypotheses are assumed to be tenable, and no other inferences are made, there is no argument for or against «*Logare*» having a mean-

ing, M_1 , that does not apply to «*Mogare*» having that meaning. That is, there is, on the assumed basis, no reason for attributing different meanings to them. There is, however, an argument for regarding them as synonymous, namely the similarity of inferences 2 and 3. By saying that it is a pro-argument, we do not say anything about the strength of the argument. The strength (power of confirmation) may be taken to be very small, but significantly greater than zero.

With the foregoing as an anticipatory illustration, we now introduce the following concept:

(3) «*a*» is occurrence-synonymous with «*b*» within the occurrence classes S_a and S_b in relation to the two sets of occurrence inferences $F_1(a), \dots$ and $G_1(b), \dots$ shall mean the same as «What is said about 'a' or a's according to the set of occurrence inferences $F_1(a), \dots$, is the same (within the terminology of the analyst) as what is said about 'b' or b's according to the set of occurrence inferences $G_1(b), \dots$ ».

By 'a' and 'b' we refer to concepts that might be mentioned in the inferences, and by a's and b's we refer to denotata.

The occurrence classes S_1 and S_2 are supposed to have at least one member each. They may be delimited as in the above illustration by quoting two texts, or by some other technique.

The occurrence inferences concerning «a» or a's, that is, inferences about the designation investigated or about the things subsumable under a concept 'a' expressed by «a», are labeled $F_1(a), F_2(a), \dots$. It is presumed that they (in conformity with the requirement of step 3 of the occurrence analysis) have been made consistent.¹⁴ The same is presumed of the analogous set $G_1(b), \dots$.

If $a_1, a_2, \dots, a_i, \dots$ and $b_1, b_2, \dots, b_j, \dots$ are the members of the occurrence classes S_a and S_b mentioned in (3), $F_1(a), \dots, a_i$ will be said to be occurrence-synonymous with b_j in relation to the sets of inferences $F_1(a), \dots$ and $G_1(b), \dots$.

If the occurrence inferences from two occurrence classes—for example, from two texts written by different authors—are to be compared, it is convenient to formulate the inferences in such a way that similarities and differences, consistencies and inconsistencies, are brought to attention.

VII. INTRODUCTION OF A GROUP OF CONCEPTS

Many additional inferences may be included in the classes as a result of such a comparison, because attention is focused on new aspects of usage and opinions.

Suppose we find as continuations of the texts (1) and (2): «5 ist eine *Logare*» and «7 ist eine *Mogare*». We may view the new findings as confirmation of our previous translations and inferences. Let us include in the two sets of inferences the following ones: In the a-set: «The class of numbers '*Logaren*', intended by «*Logaren*», includes the number 5». In the b-set: «The class of numbers '*Mogaren*', intended by «*Mogaren*», includes the number 7».

In relating to the new sets of inferences, it is tempting to define «occurrence-heteronymous» in such a way that «a» and «b» in the above case have that property. We shall not do that, however, if we think it at all likely that what is said about the a's might also hold good for the b's. In the present case, I see no reason why 7 should not turn out to be a *Logare* and 5 a *Mogare*. There is no positive evidence in the occurrence sentences by which to decide the question. If the new inferences were such that what was said about the *Mogare* scarcely could hold about the *Logare*, or vice versa, this incompatibility should be expressed in the formulations of the new inferences. In using the following concepts, we have presupposed such a technique of formulation.

- (4) ««a» is occurrence-heteronymous with «b» within the occurrence classes S_a and S_b in relation to the two sets of occurrence inferences $F_1(a), \dots$ and $G_1(b), \dots$ » shall mean the same as «What is said about 'a' or a's according to the set of occurrence inferences $F_1(a), \dots$ is inconsistent with what is said about 'b' or b's according to the set of occurrence influences $G_1(b), \dots$ ».

Consider the example of an occurrence inference from one text unit that reads, «No plutocracies can be democracies in the sense of the author», and an occurrence inference from a second text unit that reads, «Some plutocracies can be bourgeois democracies in the sense of the author». Let «democracies» and «bourgeois democracies» be the expressions that we wish to investigate.

If we disregard the reference to authors in the occurrence inferences, and construct two new sentences by substituting one expression for the other, the following four sentences are formed:

«No plutocracies can be democracies.»

«Some plutocracies can be democracies.»

«No plutocracies can be bourgeois democracies.»

«Some plutocracies can be bourgeois democracies.»

The first and second sentences are consistent, as are the third and fourth. If we disregard the difference between the two expressions investigated, and interpret the text as if only one expression had been found at the occurrence places of the two expressions, then inconsistencies are made possible (provided the occurrence inferences are accepted as tenable).

The term «inconsistent» in definition (4) must be interpreted in connection with a procedure of substitution as outlined in this example. Heteronymy is asserted if there is inconsistency in the sense of inconsistencies within the class of sentences constructed by substituting the crucial expressions «a» and «b» for each other in the inference formulations and by eliminating the references to authors.

(5) ««a» is incomparable to «b» in respect to occurrence synonymy within the occurrence classes S_a and S_b in relation to the two sets of occurrence inferences $F_1(a), \dots$ and $G_1(b), \dots$ » shall mean the same as «What is said about 'a' or a's according to the set of occurrence inferences $F_1(a), \dots$ is different from, but not inconsistent with, what is said about 'b' or b's according to the set of occurrence inferences $G_1(b), \dots$ ».

In the survey of complex relationships, we may find the following symbol helpful as a condensed expression of the definiendum of (3):

$\text{Synocc}(aS_aF(a), bS_bG(b))$

Since the reference to authors and their intention is basic, in the occurrence inferences one may include the reference in the symbol:

$\text{Synocc}(aP_1S_aF(a), bP_2S_bG(b))$

In our general symbol for synonymy sentences with indications of reference classes, S_a and S_b correspond to the delimitation of situations

VII. INTRODUCTION OF A GROUP OF CONCEPTS

and $F(a)$ and $G(b)$ to reference classes of the kind introduced in earlier chapters.

Corresponding to the special cases of synonymy sentence is the case of one expression being investigated, but different classes of occurrences:

$$\text{Synocc}(aP_1S_aF(a), aP_2S'_aF'(a))$$

Other cases of interest are those of $P_1 = P_2$, and of P_1 being an author analyzed and P_2 being the analyst. In the latter case, the analyst asserting the occurrence synonymy is the one who has made the text containing the occurrences of «b». He is usually considered to know how he has used his term «b», and occurrence analysis with implicates and inferences might therefore be considered superfluous. In principle, there is no difference, however, between an investigation of past happenings produced by oneself and an investigation of happenings produced by others.

From the manner of arriving at the conclusion that two expressions are occurrence-synonymous, it follows that that relation must be reflexive, symmetrical, and transitive, provided the marginal references (the P's, S's, and F's) are held constant.

VII.20. Occurrence Synonymy and Connotational Occurrence Analysis

The Zaslavski analysis (pages 332–33) proceeds from an investigation of a text containing 192 use occurrences of an expression.¹⁵ In the symbols of the preceding section, P_1 is Zaslavski; text number 1 is *La démocratie soviétique*; and the crucial expression, «a», is «démocratie». The class S_a contains the occurrences a_1, a_2, \dots, a_{192} , that is, all use occurrences in the text.

The connotational occurrence analysis of the Zaslavski text may, if the concepts of section 18 are adopted, be said to culminate in the evaluation of tentatively asserted interpersonal occurrence synonymies, namely, synonymies between «a» in Zaslavski's text and rather complex expressions in the analyst's text. How the latter are interpreted the analyst may feel certain about and find unnecessary to investigate by studying his own terminology.

With regard to his intended public, however, the question is not as simple; but it is part of the analyst's job to make use of expressions (such as

«b» terms of the synonymity relations) that the members of his intended public do not need to subject to occurrence analysis. It should be enough for them to read the metaoccurrence b_0 in the tentatively asserted occurrence synonymity. That it is enough is the analyst's claim if he, as we have done in the concluding sections of our Zaslavski analysis, formulates tentative Ds-formulations as conclusions without adding something like the following explanatory note: «as to the meaning of the terms used in my definientia, they are intended to be used as you will find them used in the following text: ---». Notes of this kind are not rare in the literature of philosophic analysis, but the more frequent case is that in which the analyst merely puts forth his definientia as self-explanatory.

The lack of discussion regarding the formulations used as definientia of the descriptive definitions does not owe to a belief that they are unambiguous. If they were made more precise, however, their number would have to be much greater, and the nuances made explicit by the precisizations would mostly be such that the analyst could not find any evidence favoring one rather than another. By keeping the descriptive definitions vague and ambiguous—within certain limits—he avoids complicated surveys of possibilities that lead nowhere. By leaving the ambiguity unmentioned, on the other hand, he creates possibilities of misunderstanding owing to differences between himself and his intended public regarding how the scope and limits of the ambiguities are conceived.

Interpreting the conclusions of connotational occurrence analysis in terms of occurrence synonymity, we encounter the question, What is the set of inferences $G_1(b)$. . . ?

The analyst tries to pick out Ds-definitions that are consistent with all occurrence inferences, $F_1(a)$. . . That is, if «b»—the definiens formulation of the Ds-definition—is adopted and «b» is substituted for «a» in the text analyzed, it is the analyst's contention that if the author of the text had interpreted «b» as does the analyst, he would have accepted the occurrence sentences. From the new text, with «b» instead of «a», the analyst would make exactly the same inferences that he made from set $F_1(a)$. . . That is, the two sets of inferences $F_1(a)$. . . and $G_1(b)$. . . would be identical.

In this way the concepts of occurrence synonymity can be applied to the conclusions of connotational occurrence analysis—the descriptive definitions of usage.

VII. INTRODUCTION OF A GROUP OF CONCEPTS

Let us apply those views to the simple illustration of section 19. Suppose the analyst interested in connotations tentatively asserts this hypothesis: «*eine Logare*» in text (1) (with supplements) means the same as «a prime number». Provided that previously accepted translations are also used, we get the following form for text (1): «*Wenn ein product zweier natural numbers a, b durch eine prime number p teilbar ist, so muss wenigstens der eine der Faktoren a, b durch p teilbar sein; 5 ist eine prime number*».

The English words «product» and «natural numbers» mark out places in the text at which the analyst, by using auxiliary hypotheses, has translated parts of the original text into his own language. All English words in the text are supposed to be interpreted as intended by the analyst. If the author of the text were to use that interpretation, the analyst contends, he would accept the new text as intrapersonally synonymous with its original text. The analyst would make inferences from the new text that result in a set of inferences $G_1(b) \dots$, which assert (in the terminology of the analyst) the same about the b 's as the inference class $F_1(a) \dots$ said about the a 's.

Innumerable descriptive definitions are such that if the definiens « b » is inserted for « a », text (1) is made to assert things that are acceptable in ordinary arithmetic. Instead of «prime number» one might insert «natural number», or «number divisible by 3 and 5», or «5, 6, and 7», or «perfect number», or designations expressing any other finite or transfinite class of natural numbers that has 5 as a member. (In the esoteric terminology of Cantor, the cardinal number of descriptive definitions satisfying the conditions is a transfinite number, namely alef-one. All subclasses of a definite class [cardinal number alef-one] of prime numbers give descriptive definitions and satisfy the requirements of the occurrence inferences, together with those of arithmetic. The cardinal number of that class of subclasses is alef-one.)

Actually, text (1) is a transcription of a theorem stated in the *Encyklopädie der Elementar-Mathematik* (1906/07: 2:48): «[w]enn ein Produkt zweier Zahlen a, b durch eine Primzahl p teilbar ist, so muss wenigstens der eine der Faktoren a, b durch p teilbar sein».

It is instructive to see how many kinds of descriptive definitions of the term «*Primzahl*» result, if the definitions are used to reformulate the account of such numbers in the *Encyklopädie*, in theorems or arguments that are acceptable in arithmetic. This holds good, of course, only if metaoccur-

rences are ignored. (There are good reasons to ignore them in proofs: it cannot be proved mathematically that any normative definition ever has been followed.)

VII.21. Occurrence Preciseness

With ‘occurrence synonymy’ as a basic concept, concepts of ‘occurrence synonymic alternative’, ‘occurrence interpretation’, and ‘occurrence preciseness’ can be introduced. We shall not here make any systematic exposition but will follow closely the lines of chapter 1.

The term «synonymic alternative» was introduced in chapter 1 so that we would have a short name for all expressions that sometimes by someone are interpreted to mean the same as a given expression. A concept of ‘occurrence synonymic alternative’ can be constructed by letting the marginal references, including or not including the reference to inference classes, undergo variation. The former alternative will be preferred here.

Suppose we have found:

$$\text{Synocc}(aP_1S_aF(a),bP_2S_bF(b))$$

We then ask, Are there other expressions, «c», «d», . . . , that to the same or other persons, relative to the same or other occurrence classes and inference classes, are occurrence-synonymous with «a»?

Let us suppose we find other expressions by variation of marginal references:

$$\text{Synocc}(aP_1S_aF(a),BP_2S_bF(b)) \ \& \ \text{Synocc}(aP_1S_aG(a),cP_2S_cG(c))$$

$$\text{Synocc}(aP_1S'_aF'(a),P_2S_dF'(d)) \ \& \ \text{Synocc}(aP_1S_aF(a),eP_3S_eF(e))$$

‘Occurrence synonymic alternative’ may now be introduced as follows:

- (1) ««b» is an occurrence synonymic alternative of «a»» shall mean the same as «There is at least one pair of persons, one pair of occurrence classes of «a» and «b», one pair of inference classes $F(a)$ and $F(b)$ such that in relation to a set of such pairs, «a» is occurrence-synonymous with «b»».

VII. INTRODUCTION OF A GROUP OF CONCEPTS

In symbols:

$\text{Synoccalt}(b,a) = \text{D}$
 $(\text{Ex}) (\text{Ey}) (\text{Ez}) (\text{Et}) (\text{Eu}) (\text{Ev}). \text{Synocc}(\text{axyz}, \text{btuv}) \ \& \ \text{Pers}(\text{x}) \ \& \ \text{Pers}(\text{t})$
 $\ \& \ \text{Occl}(\text{y}) \ \& \ \text{Occl}(\text{u}) \ \& \ \text{Infcl}(\text{z}) \ \& \ \text{Infel}(\text{v})$

We may introduce, as analogous to the term «preciseness» of chapter I, a concept of 'occurrence preciseness':

(2) «*b*» is more occurrence-precise than «*a*» shall mean the same as «The class of occurrence synonymic alternatives of «*b*» is a genuine subclass of the occurrence synonymic alternatives of «*a*», and that subclass is not the zero class».

In the illustration on pages 386–87, there might be a relation of preciseness between «*a*» and «*b*», if, for example, «*b*» permits «*c*» and «*d*», but not «*e*», as occurrence synonymic alternatives.

In practice, it is unlikely that expressions in the vernacular will be found to stand in relations of occurrence preciseness to each other, because of the complexity of usage. Only if we severely limited the occurrence classes and inference classes, might the requirement of the definition of occurrence preciseness be fulfilled. Seldom, however, is there use for investigations on such a narrow basis.

The importance of the occurrence preciseness must be judged from its use in simplifications or models of usage within technical terminologies, and from its use as the simple limiting case of relations by which one expression, «*b*», permits rather numerous or important synonymic alternatives, and another, «*a*», permits very few or unimportant ones that are common to both; or, as simple limiting cases of relations by which the classes of occurrence inferences are nearly the same, the differences consisting in inferences that are of little importance.

The practical fruitfulness of the concepts introduced in this section is not yet established, because few attempts have so far been made to use them; this creates a situation that is rather common at the first stages of empirical investigations.

VII.22. Occurrence Analysis Disregarding Authors and Intended Meanings: Authoritative Systems as Guides for Interpretation

The connotational occurrence analysis described in chapter 6 and the occurrence synonymy concept of this chapter refer to intended meanings and opinions of an author and the intended meanings of the analyst. This does not imply that private states of consciousness are somehow the basic events related in the interpersonal synonymy hypotheses. It is not presumed in the analysis that intentions have an introspective nature and cannot be defined behaviorally or by a combination of behavioral and introspective entities. Nevertheless, the reference to intention makes the introduced concept of occurrence synonymy rather special.

In this section we shall introduce a concept that does not refer to intentions or opinions of persons using expressions in communication.

In theories of interpretation adapted to interpretation of laws in democracies, it is usual to talk of «the meaning» of a formulation as something independent of any intention expressed or implied by lawgivers. In mathematics, the formulations of proofs have an interest independent of what the authors mean to prove. In general, we are interested in a text more or less independently of exactly what its author or authors may have intended to express and also more or less independently of specific opinions they have held about subjects directly or indirectly determining the wording of the text.

In connection with precisizations and explanations of «meaning», as used to refer to intended meanings, there is a place for a concept of nonintentional occurrence synonymy.¹⁶

Suppose someone makes the following proclamation:

«This text, T, shall guide us; it shall be valid for us. In interpreting the text, however, we shall not try to fathom the exact meaning that its words had for its authors. We shall take the usage within our community (or: our competency group) as the basis for our interpretation of the words of each sentence or paragraph. Further, if usage is ambiguous, and the interpretations result in assertions that are more or less consistent with the opinions of our community, the interpretation to be considered the valid one will be the one that is most in harmony with those opinions».

VII. INTRODUCTION OF A GROUP OF CONCEPTS

If the text *T* is interpreted along the lines suggested by this proclamation, there will be a clash between the assertions of *T* and the opinions of the competency group only if all interpretations of a sentence that are consistent with the usages of the competency group result in assertions that are incompatible with the opinions of the competency group. The suggested manner of treating *T* makes it predictable that interpretations change with time, because of changes in usage and opinions within the competency group. One may, however, accept as a postulate the existence of a definite, consistent system of usage and opinions within the competency group at a definite time. In practice, one may accept a system of rules for guiding opinion surveys such that it is possible to identify and ascertain the opinion of the competency group on any question likely to emerge.

The quoted proclamation illustrates only one kind of background for the establishment of criteria of interpretation that lack reference to an author's intended meanings and opinions other than those that can be construed on the basis of his text. The so-called nonintentional occurrence analysis differs from that described in chapter 6 in the following particulars:

Step. 1. Occurrences are always delimited by reference to texts, not by reference to persons.

Step. 2. The implicates are constructed as illustrated by the following reformulations of the implicates quoted on pages 307–08.

The first implicate of occurrence sentence 21 might be thus formulated: «as used at occ. 21, the term «democratic» expresses—interpreted consistently with the system Σ of rules of usage—something that makes it meaningful to say about a state order that it is truly democratic, or that it is not truly democratic, or that it is democratic, or that it is not democratic».

The second implicate of occurrence sentence 21 might be thus formulated (cf. pages 307–08): «as used at occ. 21, the expression «state order» denotes—interpreted consistently with the system Σ of rules of usage—things that, with the exception of one, are subsumable under a class 'not truly democratic state order'».

It is here presumed that a system Σ , consisting of subsystem Σ' of rules of usage and a subsystem Σ'' of opinions, is given somehow. As it cannot be given explicitly and completely in the form of a system of sentences, it must in part be hypothetically structured. It must be presupposed, how-

ever, that there are rules such that for every occurrence, the system can be consulted. This means that every implicate must, in principle, be derived by rules, usage, and syntax ascertained not to be inconsistent with those that the competency group would seem to use. That is, the analyst must, by fresh investigations of the verbal behavior of the competency group or by use of generalizations already obtained and explicitly referred to as part of the system Σ , ascertain that his construction of implicates is not inconsistent with the system.

The standard form of implicates (page 310) may be reformulated thus: «at occurrence number x of the term « a » it expresses—if interpreted in accordance with the system of rules of usage—something that makes --- subsumable under ' a '».

It was said in the exposition of ordinary occurrence analysis that, when one analyzes the use of the term «state order» in Vyshinsky's text, all his opinions about state orders are relevant. Any limitation of the investigations to a narrower field can be justified only by limitations in research facilities. In the system-centered occurrence analysis, all that Vyshinsky says about state orders, except what he says in the chosen text, is in principle irrelevant. Moreover, what he says in the text is to be interpreted consistently with the rules of usage of the system and, as far as possible, in such a way that no opinions can be said to be expressed in the text that are in conflict with the opinions included in the system.

Step 3. A decisive step in the intention-oriented occurrence analysis is made when the analyst tries to translate the implicates and occurrence sentences (minus the «term « a »» under investigation) into his own language and that of the prospective readers of the amount of his analysis. No such step is made in the nonintentional analysis, since no author is recognized. The text has already, in the process of constructing the implicates, been interpreted in accordance with the authoritative canon of usage.

In the intention-oriented analysis, the interpretations leading to occurrence inferences (cf. 3, page 312) should not transgress the definiteness of intention of the author—a most difficult thing about which to have a well-founded opinion. In the nonintentional analysis, this is not a problem; the definiteness of intention of the competency group is here relevant, not that of the author or authors. It is, as a basic premise, taken for granted that the analyst can, by proper procedures, ascertain the usage and opinions of this

VII. INTRODUCTION OF A GROUP OF CONCEPTS

group, and therefore also make investigation of the definiteness of intention with in the group.

Just as in the case of intentional analysis, questions of consistency among inferences play an important role in shaping a definitive set of inferences on the basis of which descriptive definitions of usage are tested.

Step 4. This step is taken only if one wishes to conclude with tentative descriptive definitions of usage. In the nonintentional analysis, such definitions will not have the form adapted to the intention-oriented analysis (cf. pages 319–20). That form should be reformulated in the following direction: «the designation T_0 expresses the same as T_1 at occurrence numbers --- of the text, the same as T_2 at occurrences numbers . . . of the text, ---». T_1, T_2, \dots are here definiens formulations within the terminology of the system Σ . If we assume that the competency group in practice operates as one person, the descriptive definitions of the nonintentional analysis are intrapersonal synonymy hypotheses. The analyst must (of course) use his own terminology and try to understand both the text and the utterances of the competency group in his own terms, but the translations into the language of the analyst may be considered only as an episode: the conclusions are intended to be interpreted within the range of the authoritative system Σ .

Now that we have outlined a nonintentional occurrence analysis, we are prepared to compare an occurrence synonymy concept adapted to such an analysis with the already introduced concept.

In formulation (3) we need only change «within the terminology of the analyst» to «within the terminology of the accepted system» to make it adapted to the system-oriented analysis. The inconsiderableness of the change owes to the reliance of (3) on a concept of ‘sets of inference classes’ presumed to have been introduced in connection with step 3 of the ordinary occurrence analysis. An introduction of a concept adapted to the nonintentional analysis must, if made complete, refer to a concept of ‘sets of inference classes’ connected with step 3 of the system-oriented analysis.

VIII

Synonymity Questionnaires in Use

VIII.1. Scope of the Empirical Studies Reported in This Chapter

By Qsxy concepts or tests of the kinds introduced in chapter 7, synonymity sentences can be transformed into hypotheses that are, in principle, testable by relatively simple procedures. In practice, the questionnaire procedures schematically outlined in chapter 7 are not always applicable, and even in cases in which they might seem well adapted to the questions posed, they need careful discussion. In contemporary social science, the methodology of questionnaire methods has contributed much to the refinement of the rather crude techniques in use two or three decades ago, and it has also shown, by empirical investigations, how imperfections in the wording of the questionnaires and in other stages of the procedure influence results.

In this chapter it is impossible to report on more than a handful of the empirical studies that have made use of Qsxy questionnaires or related kinds. Each study that has been undertaken with the aim of contributing to discussions on usage would require extensive space to be reported reliably. Some of the studies whose authors have used questionnaires identical or similar to the Qsxy questionnaires are listed in the references starting on page 505.

This chapter will be devoted to the exposition of a series of studies illustrating the kinds of difficulties that immediately turn up, even when the simplest questionnaires, especially Qs1, are applied to concrete problems of usage and communication. The studies are selected not only because of the simplicity of the procedures employed, but also because of the interest in the results for assessing the prospect of a general hypothetico-deductive system concerning use regularities.

Among the theorems in such a system, tentatively outlined, some con-

VIII. SYNONYMY QUESTIONNAIRES IN USE

cern basic regularities of answers to different questionnaires. A group of the theorems affirms the existence of a high positive correlation between answers to pairs of questionnaires of the kind Q_{s1} , in which the crucial expressions T and U are substituted for each other. Roughly speaking, these theorems concern the empirical symmetry of Q_{s1} A-synonymity—the tendency to interpret T to mean the same as U, if U is interpreted to mean the same as T. Other theorems concern corresponding properties of transitivity.

VIII.2. Empirical Symmetry of the Relations of Q_{sxy} -Synonymity

The expression « Q_{sxy} -synonymity» is used as a collective name for the synonymity relations defined by the concepts or tests of chapter 7. Only Q_{s1} A, Q_{s1} B, Q_{s2} A, Q_{s2} B, . . . , Q_{s5} B are referred to in the following.

In formal logic a relation R is called «symmetrical in the class K» if, for any two elements x and y of the class K, the formula xRy («x has the relation R to y») always implies the formula yRx . If xRy always implies $\neg(yRx)$, the relation is called «symmetrical in the class K». (For elaborations, see Tarski 1946: 93ff.; Cooley 1942: 108.)

In this work we need a pair of closely related, but somewhat broader concepts. If yRx does not hold good for any two elements x and y of the class K, but for most, provided xRy holds for any two elements, we shall still be able to speak of the relation R as being symmetrical. To avoid misinterpretation of the term, we shall use the designation «empirical symmetry» or «synthetical symmetry».

If there is a sufficiently high positive correlation between xRy and yRx to warrant the assertion of an empirical theorem, R will be said to be «symmetrical». By this normative definition the possibility is not *per definitionem* excluded that xRy implies yRx . In that case the correlation must be expected always to be equal to 1. On the other hand, if correlations less than 1 are found, we may rule out the possibility of implication. «Symmetry» may accordingly be translated in the following by the designation «logical or empirical symmetry» or «analytical or synthetical symmetry».

For each of the synonymity concepts or tests introduced in relation to the questionnaires of chapter 7, there may be asked a question of the following kind:

VIII.2. Empirical Symmetry of the Relations of Qsxy-Synonymy

If an expression «a» is Qsxy-synonymous with an expression «b», what is the chance that «b» is Qsxy-synonymous with «a»?

In other words, the question of symmetry can be raised in relation to each concept or test introduced by the questionnaires.

In chapter 2, section 6, a term «synonymous» was introduced in such a way that if x is synonymous with y, y is *per definitionem*, and therefore by implication, synonymous with x. When the term is thus introduced, there is no need for investigations of empirical kinds to establish the symmetry of the relation synonymy. Such investigations would in any case be difficult to procure because of the imperfections of the normative definition of «synonymy»; see (1) in chapter 2, section 6. The definiens expressions contain as a central term the vague word «meaning». From the point of view of empirical research, the normative definition (1) is an *obscurum per obscurius*.¹

Introduced as in chapter 7, the relations of synonymy are not *per definitionem* symmetrical. It remains to be shown whether they are or are not symmetrical in an empirical or synthetical fashion.

One of the main contentions of this chapter may be thus roughly formulated:

On the basis of available evidence, Qsxy-synonymy relations are symmetrical. The symmetry does not, however, hold without exceptions.

As a matter of fact, many series of answers reported below contain a percentage of disconfirming instances of symmetry too high to be considered a normal percentage of exceptions to an empirical theorem. These series, however, are not considered a fair sample, for reasons that will be explained later. Other series show a satisfactory correlation between xRy and yRx for purposes of theorem construction.

In chapter 2, section 6, it was proved that if «synonymy» is defined in such a way that it is a symmetrical relation, and if «synonymic alternative» is defined as in chapter 1, section 10, then the relation of synonymic alternative will be analytically symmetrical.

From this it follows that if it is (empirically) found that a synonymy relation holds between certain expressions and that the relation is symmetrical, then the relation of synonymic alternative between those expressions will also hold good. Thus, confirmatory instances of an empirical theorem about symmetry of synonymy will also constitute confirmatory instances of an analogous theorem concerning synonymic alternatives. Because of

VIII. SYNONYMY QUESTIONNAIRES IN USE

this, we shall not mention anything about the relation of synonymic alternatives in the account about symmetry.

Some might object, against the program of testing symmetry theorems, that considering the triviality and obviousness of the symmetry of fruitful concepts of synonymy relations, the program is not worth carrying out. Such an objection seems to stem from a neglect of the requirements necessary to arrive at reliable knowledge expressed in systems of theorems. Whatever is not analytical should be tested. How many tests should be performed is another question. At least some testing must be done to show that the procedures involved are practicable. As for the question of fruitful concepts of symmetry, any fruitful concept that does not make the theorems about symmetry analytical will make them vulnerable to all kinds of complications inherent in empirical procedures. There will be exceptions, or at least doubtful cases.

VIII.3. Empirical Evidence of Symmetry of Synonymy Relations as Defined by Questionnaires

Questionnaires of Type Qs1

The general form of Qs1 questionnaires is given in chapter 7, page 399ff.

Text Used

All Qs1 questionnaires to be discussed in the following have a common text:

«There has been some discussion about the question of whether a greater number² than usual failed in logic at the preliminary examinations. [It is true that] a greater number than usual failed, but a greater number failed in psychology and history of philosophy than in logic».

The expression in square brackets (inserted here by the author) underwent variations; the rest of the text was kept constant.

Three types of Qs1 questionnaires, all using this text, were employed.

1. Qs1d Nos. 0.1–0.6 asked for synonymy between *designations*.
2. Qs1 Nos. 1.1–1.6 were the analogous questionnaires asking for *sentences containing designations*.
3. Qs1 Nos. 2.1–2.6 concerned *sentences*.

VIII.3. Empirical Evidence of Symmetry of Synonymity Relations

Crucial Sentences, T and U

The sentences T and U used in QsI Nos. 2.1–2.6 were the following pairs:

QsI No. 2.1	It is true that a greater number than usual failed. It is perfectly certain that a greater number than usual failed.
QsI No. 2.2	It is perfectly certain that, etc. It is true that, etc.
QsI No. 2.3	It is the case that, etc. It is perfectly certain that, etc.
QsI No. 2.4	It is the case that, etc. It is true that, etc.
QsI No. 2.5	It is perfectly certain that, etc. It is the case that, etc.
QsI No. 2.6	It is true that, etc. It is the case that, etc.

Instructions

The instructions were slightly different for each of the three kinds of questionnaires. The instructions for QsI No. 2.1 are stated fully in chapter 7, page 400. Those for QsI No. 1.1 read:

This text was offered you as an example of a text containing the expression [«it is true that»]. Let us call this expression T. What I should like to know is the following:

Suppose the expression [«it is perfectly certain that»] (let us call it U) had occurred in the place of T in the text. Would the sentence containing U have expressed to you the same assertion as the sentence containing T did when you read T?

In QsI No. 0.1 the last sentence reads, «Would U have expressed to you the same as T did when you read T?»

Order of Presentation of Questionnaires

The respondents were given QsI Nos. 0.1–0.6, Nos.1.1–1.6, Nos.2.1–2.6, or a mixture. The order of presentation varied. In some series, a questionnaire in which an expression «b» was substituted for «a» was not immediately followed by a questionnaire in which «a» was substituted for «b». Instead, a questionnaire containing a third expression, «c», was introduced.

Subjects Tested

The subjects tested were students. Most of them were sophomores, ranging in age from about eighteen to twenty. They were taking or had already

VIII. SYNONYMITY QUESTIONNAIRES IN USE

taken an introductory course in logic with some excursions into semantics. This is a required course for all students at the University of Oslo.

The subjects were not told about the aim of the questionnaires.

Main Results

Table 3 shows the results obtained from some of the Qs1 questionnaires (see table 4 for additional results).

In columns 2–5, four categories of answers are distinguished:

Syn(ab) & Syn(ba)	Affirmation of both synonymities. Classed as full confirmatory instance of the theorem asserting Qs1A-synonymity.
Syn(ab) & -Syn(ba)	Affirmation of the first, negation of the second. Classed as full disconfirmatory instance.
-Syn(ab) & Syn(ba)	Negation of the first and affirmation of the second. Same classification.
-Syn(ab) & -Syn(ba)	Negation of both synonymities. Classed as weak confirmation.

Column 6 subsumes all the answers that were difficult to classify. Column 8 gives the total number of cases of confirmations, full or weak; and column 9 gives the number of full cases of disconfirmation.

Preliminary Discussion of Results

Of 436 pairs of answer, only 9 are clear disconfirmatory instances of symmetry. This we take as a very satisfactory main result. More cannot be said until we discuss the nature of the disconfirmatory instances (section 7), below.

The unclassifiabiles—roughly 12 percent—are cases in which the answers to the synonymity questions were more or less obscure, ambiguous, or indirect. Much effort has been made to reduce such unsatisfactory answers, but with little success. The marked variation in number of «unclassifiabiles» from test to test owes partly to the use of different criteria of classifiability.

The figures indicating synonymities are rather small to warrant statistical discussion. It seems, however, that «true» and «perfectly certain» are not as often conceived as synonymous as are «is the case» and «perfectly certain», and «is the case» and «true». This is in agreement with results obtained by a considerable number of other questionnaires, most of which must be left unmentioned in this work.

No marked differences seem to be attributable to a shift from question-

Table 3: Symmetry of Qs1A-Synonymy Relations

Total	333	3	6	40	54	436	373	9

VIII. SYNONYMITY QUESTIONNAIRES IN USE

naires on designations to those concerning sentences. This justifies our tentative parallel treatment of designations and sentences.

Further Qs1 Questionnaires

The foregoing questionnaires all used declarative sentences as T and U. Pairs of questionnaires were also constructed to test symmetry relations between imperatives and between question sentences. The general schema of the questionnaires is the same as before; therefore, they are all classed as Qs1.

The text presented to the respondents in Qs1 No. 2.7 was «In the textbook of logic for the preliminary examination, some of the technical terms are defined. [In the lectures, those definitions are followed.]»

The instructions were the same as for Qs1 Nos. 2.1–2.6. The sentence in square brackets functioned as T, and for U we selected «In the lectures those technical terms are used in accordance with the definition».

In Qs1 No. 2.8, U was found in the text and T was introduced in the instructions.

The results of this pair of questionnaires, Qs1 Nos. 2.7 and 2.8, were then compared with the results of a pair containing imperatives, Qs1 Nos. 1 and 2. The text of No. 1 was «In the textbook in logic for the preliminary examination, some of the technical terms are defined. [Follow those definitions!]» In the instructions, the respondents were asked to substitute «Use those technical terms in accordance with the definitions!» for the bracketed sentence. The synonymity question asked, «Would U! have expressed the same imperative to you as T! expressed when you read T!?»

Qs1 No. 2 was exactly like No. 1, except that U! was substituted for T! and vice versa.

The text of Qsq1 No. 1, with question sentences, read: «After the preliminary examination, autumn 1949, A. N. said to some of the candidates, «In the textbook some technical terms are defined. [Did you follow those definitions?]» The question called T? was then placed in relation to U?, «Did you use those technical terms in accordance with the definitions?»

In the second questionnaire, Qsq1 No. 2, T? was replaced with U? and vice versa.

Main results

Table 4 displays the main results of the six questionnaires tabulated.

Table 4. Symmetry of Qs1A-Synonymy Relations (continued)

VIII. SYNONYMY QUESTIONNAIRES IN USE

Preliminary Discussion of Results

The frequency of disconfirmatory instances, 17 out of 139, is much greater than in the first series of experiments (9 out of 436). It is not clear why this is so. It may owe in part to the manner in which the questionnaires were presented: they were shuffled together with numerous other questionnaires of other types in such a way that the respondent, when answering QsI No. 2.7, for example, could not easily know that there was any connection between that questionnaire and QsI No. 2.8, even though he had already answered QsI No. 2.8. Thus, if he had been very uncertain whether to answer yes or no to No. 2.8, and finally answered yes, this decision may not have influenced him in the direction of a positive answer to QsI No. 2.7. The respondents were prevented from looking at questionnaires previously given and answered.

The large number of disconfirming instances might also be explained by the special text used in these questionnaires. The discussion of these possibilities is taken up in section 9.

During interviews with the seventeen people who gave disconfirming answers, sixteen of them modified their answers so that only one disconfirming instance remained. This kind of interview is discussed below (page 470).

In table 5, I have detailed the degree to which answers to synonymy questions of declarative sentences correspond to answers related to analogous imperatives and questions. In the first column, the questionnaires used are indicated. The rest of the columns are divided into two parts, according to a classification of all respondents into those who gave at least one pair of answers that yielded a disconfirmatory instance of symmetry, and those who did not give any such answer.

As might be expected from the results reported in table 4, the answers of persons confirming the symmetry theorem show a higher correlation with changes in questionnaires than do the answers of the other respondents. As many as eleven out of twenty answers by members of the latter category are different, whereas only ten out of seventy-five answers by persons confirming the symmetry theorem differ according to kind of questionnaire.

Let us call the following theorem a «correspondence theorem of QsIA-synonymy»:

«If a person declares T and U in a text to be synonymous, he will tend to declare T' and U' in the same text synonymous, if T' is an

VIII.3. Empirical Evidence of Symmetry of Synonymity Relations

Table 5. Comparison of Answers to Qs1 No. 2.7, Qsi1 No. 1, and Qsq1 No. 1

	Respondents Not Giving Disconfirmatory Instance of Symmetry			Respondents Giving Disconfirmatory Instance of Symmetry		
	<i>Same</i>	<i>Diff.</i>	<i>Unclas.</i>	<i>Same</i>	<i>Diff.</i>	<i>Unclas.</i>
Qs1 & Qsi1	26	2	4	8	3	1
Qs1 & Qsq1	23	5	4	5	5	2
Qsi1 & Qsq1	26	3	3	7	3	2
Total	75	10	11	20	11	5

imperative or question corresponding to T, and U' is an imperative or question corresponding to U.»

Here criteria of correspondence must be defined before the theorem acquires any moderately definite meaning. If criteria are such that the texts in questionnaires Qs1 No. 2.7, Qsi1 No. 1, and Qsq1 No. 1 are a set fulfilling the criteria of correspondence, the theorem is confirmed by table 5, provided the claim to validity is only a claim of rough regularity, let us say, «more than 80 percent regularity».

Questionnaires of Type Qs2

Questionnaires

Three pairs of Qs2 questionnaires were used. In each pair the crucial sentences T and U were substituted for each other. The two sentences used were:

«Not all numbers below 10 are divisible by 2 and 3.»

«Not all whole numbers below 10 are divisible by 2 and 3.»

Many respondents did not discover the difference in formulation at once but had to reread the sentences.

The three alternative answers—with abbreviations—were:

«Yes, in *all* situations.» Abbr.: a.

VIII. SYNONYMY QUESTIONNAIRES IN USE

«In *some* situations, not in all.» Abbr.: s.

«No, *not* in any situations.» Abbr.: n.

Qs2 Nos. 1 and 2 were formulated in accordance with the standard quoted in chapter 7 (see page 403 ff.). Confusion about these formulations among the respondents led us to prepare an additional instruction given as an appendix to the questionnaires. The questionnaires that included this instruction are called Qs2 Nos. 3 and 4. In the appendix it was stated at length that the questions did not relate to any situation or text in which *both* T and U occurred, but to a situation in which *either* T *or* U occurred.

Even with this additional instruction, some respondents seemed to misunderstand the question. The instruction was therefore again reformulated, the resulting questionnaires being called Qs2 Nos. 5 and 6.

In Nos. 1, 3, and 5, the expression «whole numbers» was used in U; in Nos. 2, 4, and 6, it was used in T.

Main Results

In table 6, which displays the results, the abbreviation «a» stands for a combination of two answers: the answer «all» to the first questionnaire presented, and the answer «all» to the second questionnaire. Abbreviations in the other column headings are analogous.

The answer «all» to both questionnaires is taken as an instance of full confirmation of symmetry of Qs2A-synonymy. The answer «some» to both questionnaires is taken as an instance of weak confirmation of the same. If, for example, a person distinguishes between two kinds of situations, the answer «some» to the first questionnaire might reflect his opinion that synonymy holds good in the first, but not in the second kind. The answer «some» to the second questionnaire might reflect his opinion that synonymy holds good in the second, but not in the first kind. Excluded by the answer «some» to both questionnaires are the disconfirmatory opinions «all» in relation to the first, and «none» or «some» in relation to the second, or vice versa. The uncertainty left in cases of «some» answers to both questionnaires justifies our taking the answers as confirmatory, but less strongly confirmatory than the straight answers «all». This also holds for «none» answers to both questionnaires. A theorem asserting asymmetry rules out such a combination. A theorem asserting symmetry does not exclude the combination. It is taken as weak confirmation.

VIII.3. Empirical Evidence of Symmetry of Synonymity Relations

Table 6. Symmetry of Qs2A-Synonymity Relations

Qs2 Nos.	aa	ss	nn	as	an	sa	sn	na	ns	Total	Confirmatory Instance	Dis- confirmatory Instance
1 & 2	2	11	7	0	0	4	3	0	1	28	20	8
3 & 4	6	6	1	1	0	1	0	1	0	16	13	3
5 & 6	6	22	11	2	0	1	1	0	2	45	39	6
Total	14	39	19	3	0	6	4	1	3	89	72	17

Table 6 shows a very high number of disconfirmations (8 out of 28) at the beginning of the investigations, then successive improvement with changes in the questionnaires (6 out of 45 at the end). However, even after two changes, disconfirmations make up more than 10 percent of the cases.

Questionnaires of Type Qsi3

Two pairs of questionnaires of the kind described on page 406, and called Qsi3 Nos. 1–4, were used. The «i» in «Qsi3» refers to the fact that T and U were imperatives:

«You shall not kill!»

«You shall under no circumstances kill!»

The first imperative was used as T in Qsi3 Nos. 1 and 3; the second, in Nos. 2 and 4.

The three alternative answers offered in Nos. 1 and 2 were listed as quoted on pages 461–62; in Nos. 3 and 4, the order of presentation was reversed:

«No, not in any situations.

In some situations, not in all.

Yes, in all situations.»

This variation in the order of presentation of alternatives was the only difference between the two pairs of questionnaires. The reasons for adopting such a modification are given in section 10, page 489.

VIII. SYNONYMITY QUESTIONNAIRES IN USE

Table 7. Symmetry of Qsi3A-Synonymity Relations

Qsi3 Nos.	aa	ss	nn	as	an	sa	sn	na	ns	Total	Confirmatory Instance	Dis- confirmatory Instance
1 & 2	8	41	2	0	0	3	3	0	0	57	51	6
3 & 4	11	24	9	0	0	0	2	1	0	47	44	3
Total	19	65	11	0	0	3	5	1	0	104	95	9

Main Results

The results are presented in table 7. Just as occurred in relation to Qs2, there is one case of «na» or «an», that is, of extreme asymmetry. In all, disconfirmatory cases make up somewhat less than 10 percent of the total.

Questionnaires of Type Qs4

Two pairs of questionnaires on indicative sentences were used, and a single questionnaire containing an imperative. One of them, Qs4 No. 1, is quoted here in full:

Text

Not all states are democracies. It is true that Norway is a democracy. It is not true that Spain is.

Instructions

This text was presented to you as an example of a text that contains the formulation «It is true that Norway is a democracy» (T).

What I should like to know is:

- 1a. Do you consider it a necessary condition for the truth of T that the following formulation is true: «It is perfectly certain that Norway is a democracy»?
- 1b. Do you consider it a sufficient condition?
- 2a. Do you consider it a necessary condition for the truth of T that the following formulation is true: «It is the case that Norway is a democracy»?
- 2b. Do you consider it a sufficient condition?

VIII.3. Empirical Evidence of Symmetry of Synonymity Relations

Qs4 No. 2 was made by substituting «It is perfectly certain» for «It is true» in T. In question 1 the expression «It is true» was used, and in question 2 «It is the case».

Questionnaires Qs4 Nos. 3 and 4 were strictly analogous to Nos. 1 and 2, but the texts were different. They were the same texts used for Qs1 Nos. 1 and 2.

The sentences T and U of Qsi4 No. 1 were the same as those of Qsi1 No. 1: «Follow those definitions!» and «Use those technical terms in accordance with the definitions!»

Because it was expected that the expressions «necessary condition» and «sufficient condition» would cause confusion, an appendix with definitions and examples was given to the respondents. Even with this precaution, many respondents with the ordinary qualifications complained about «difficulties», and «lack of clearness», and so on, and one-third of the answers were unclassifiable. The questionnaire was then mailed to a group of about sixty people known for their ability to answer difficult questionnaires or for having earned high marks in the preliminary examination in philosophy, logic, and psychology. Half of the members of what we shall call our «semantic panel» answered, and for the first time we got no unclassifiable answers.

Main Results

Table 8 shows the results obtained from the «semantic panel». Qs4-synonymity is defined in such a way that positive answers to parts a and b of a question in a pair of corresponding questionnaires can be classed as instances of full confirmation. As instances of disconfirmation we have taken the combination of positive answers to parts a and b in one questionnaire and a negative answer to one or both parts of the question in the other questionnaire. The distinction between weak confirmation and irrelevancy is somewhat complicated to trace in the case of Qs4. We have, therefore, in table 8 classed the weak confirmations as irrelevant.

The results of the two pairs of Qs4 questionnaires were highly satisfactory insofar as no cases of unclassifiable answers were obtained, and disconfirmations of symmetry accounted for less than 10 percent of the total.

The results of Qsi4 No. 1 were less favorable, perhaps in part because of the wording of the text sentences T and U. It was clear from interviews

VIII. SYNONYMY QUESTIONNAIRES IN USE

Table 8. Symmetry of Qs4A-Synonymy Relations

	Full Confirmation	Disconfirmation	Irrelevant	Unclassifiable	Total
Qs4 Nos. 1 & 2	22	1	8	0	31
Qs4 Nos. 3 & 4	24	2	5	0	31
Qsi4 Nos. 1.1 & 1.2	15	3	11	2	31
Total	61	6	24	2	93

with respondents that they found the application of the expressions «necessary» and «sufficient condition» doubtful or difficult.

VIII.4. Summary of Results

To test theorems of symmetry of synonymy relations as defined by questionnaire answers, we made use of thirty-three different questionnaires of types Qs1–Qs4. A total of 861 cases were obtained, of which 89 were unclassifiable or irrelevant. Of the remaining 772 cases, 714 (or 92 percent) gave confirmatory instances, and 58 (8 percent) gave disconfirmatory instances. The results are such that they warrant continued tentative use of a theorem that roughly may be stated as follows: QsxA-synonymy relations are empirically symmetrical.³

The figures mentioned above all relate to «synonymy» in terms of direct answers to the standard questionnaires; that is, they relate to QsxA-synonymy. If discussions and interviews are taken into consideration in order to fulfill the requirement of the QsxB-synonymy definitions, other figures are obtained. They are more favorable in relation to symmetry theorems.

VIII.5. Transitivity of Synonymy Relations: Questionnaire Concepts

In formal logic, a relation R is called «transitive» if xRz is implied by the conjunction of xRy and yRz . We need in this work a broader concept 'analytic or synthetic transitivity' or 'logical or empirical transitivity' that does not require that xRz follow with logical necessity from xRy and yRz . By asserting a theorem that a relation of synonymy is transitive, we shall in the

VIII.6. *Empirical Evidence of Transitivity of Synonymy Relations*

following not express anything more than that if $\text{Syn}(xy)$ and $\text{Syn}(yz)$, then $\text{Syn}(xz)$. The «if-then» connection—in this work left unprecized—may be empirical. It asserts something for all members of certain classes of individuals, but the question of whether the assertion holds good is an empirical, not a logical, question. As a matter of fact, we shall expect a certain number of disconfirmatory cases.

Similarly, «intransitivity» stands in what follows for a concept ‘analytic or synthetic intransitivity’. A Qsxy -synonymy relation is intransitive in this terminology if the following combination is found: $\text{Syn}(xy)$ and $\text{Syn}(yz)$ and $\neg\text{Syn}(xz)$.

Introduced in the manner of chapter 2, section 6, a relation of synonymy must *per definitionem* be transitive. On the other hand, the introduction of synonymy concepts on the basis of the questionnaires described in chapter 7 does not make synonymy relations transitive by logical necessity. It is a question of empirical investigation to find out to what extent, if any, there are regularities such that one may from $\text{Syn}(xy)$ and $\text{Syn}(zy)$ expect $\text{Syn}(xz)$.

Tentatively, we adopt a series of theorems to the effect that synonymy relations as defined by the previously introduced questionnaires and interviews are transitive. For each questionnaire there will be two separate theorems of transitivity: one uses criterion A for assigning confirmation or disconfirmation values to answers, and the other uses criterion B. The conjunction of these theorems may be stated roughly as: QsxA -synonymy relations are empirically transitive.

No transitivity theorems are asserted concerning the relation of synonymic alternatives. Only occasionally will it turn out that $\text{Synalt}(xz)$ holds good when one has found $\text{Synalt}(xy)$ and $\text{Synalt}(yz)$ to hold good. The reason for the lack of transitivity of this relation is easily seen from the definition of it by means of the synonymy relation (cf. also chapter 2, section 6).

VIII.6. **Empirical Evidence of Transitivity of Synonymy Relations Defined by Questionnaires**

In all, six trios of QsI questionnaires were used to test transitivity of synonymy relations. They are all questionnaires described in previous sections:

VIII. SYNONYMITY QUESTIONNAIRES IN USE

Nos. 0.2, 0.3, 0.6
 Nos. 1.2, 1.3, 1.6
 Nos. 2.2, 2.3, 2.6

Nos. 1.1, 1.4, 1.5
 Nos. 2.1, 2.4, 2.5
 Nos. 2.1, 2.3, 2.4

Each trio of questionnaires contains three pairs of crucial expressions, (x,y), (y,z), and (x,z). The expressions used, it will be remembered, are «it is true», «it is perfectly certain», and «it is the case». For each questionnaire and each person who answers, an instance of QsIA-synonymity or lack of synonymity is recorded.

As full-weight confirmatory instances of a theorem of transitivity, we class the following kinds of results (for the sake of brevity, we have left out the symbols for person and situation):

Syn(ab) & Syn(bc) & Syn(ac)
 Syn(ba) & Syn(bc) & Syn(ac)
 Syn(ab) & Syn(cb) & Syn(ac)
 Syn(ab) & Syn(bc) & Syn(ca)
 Syn(ba) & Syn(cb) & Syn(ac)
 Syn(ba) & Syn(bc) & Syn(ca)
 Syn(ab) & Syn(cb) & Syn(ca)
 Syn(ba) & Syn(cb) & Syn(ca)

As disconfirmations with full weight, we class results that can be formulated as above except for a negation of either the third or the second or the first relation:

-Syn(ab) & Syn(bc) & Syn(ac)
 Syn(ab) & -Syn(bc) & Syn(ac)
 — — —
 Syn(ba) & Syn(cb) & -Syn(ca)

As confirmations with less than full weight, we class the following kinds of answers, which are characterized by two negations and one affirmation of synonymity:

VIII.6. *Empirical Evidence of Transitivity of Synonymy Relations*

Table 9. Transitivity of Qs1- and Qs4-Synonymy Relations

	Full Confirmation	Partial Confirmation	Dis- confirmation	Irrelevant	Unclassifiable	Total
Qs1	243	37	11	8	64	363
Qs4	44	7*	3*	8*	0	62
Total	287	44	14	16	64	425

Syn(ab) & -Syn(bc) & -Syn(ac)
 -Syn(ab) & Syn(bc) & -Syn(ac)
 etc.

As irrelevant reports, we class answers characterized by three negations of synonymy:

Syn(ab) & -Syn(bc) & -Syn(ac)
 -Syn(ba) & -Syn(bc) & -Syn(ac)
 etc.

In addition to the Qs1 questionnaires, two pairs of questionnaires of type Qs4 were used, Nos. 1 and 2, and Nos. 3 and 4, each with two synonymy questions. They are described in section 3, on page 454ff. The expressions that were varied are the same as in Qs1, and the combinations of answers are as described above for that questionnaire.

The results from Qs1 and Qs4 are tabulated in table 9.

Cases of asymmetry of synonymy produce a complication in the transitivity material. For example, if a person declares (indirectly) that «true» and «perfectly certain» are synonymous, but not «perfectly certain» and «true», transitivity can be tested on the basis of the first *or* the second report. Occasionally, the difference will have an effect on whether confirmation or disconfirmation of transitivity is found.

The three figures marked with an asterisk in table 9 (7, 3, and 8) represent transitivity calculated with the Qs4 questionnaire when we used the expression «true» in its text and «perfectly certain» in its substitution question. When we used the questionnaire with «perfectly certain» in the

VIII. SYNONYMY QUESTIONNAIRES IN USE

text and «true» in the question (which gives the trios Qs4 Nos. 1.2, 2.1, 2.2 and Nos. 3.2, 4.1, 4.2), the corresponding figures were 8, 4, and 6.

This kind of complication also exists in the material obtained with the use of Qs1. There are possible combinations other than the six trios listed at the beginning of this section. Because the results would not have been significantly different from those presented in table 9, these complications have not been alluded to in that table.

In all, 425 cases were considered, of which 80 were unclassifiable or irrelevant. Out of the remaining 345, there were 331 confirmatory and 14 disconfirmatory instances.

The percentage of confirmations out of the total number of confirmations and disconfirmations is 96. This high percentage justifies the continued tentative use of the transitivity theorems of Qsxy-synonymy.

VIII.7. Interviews Used to Study Previously Given Answers

It takes from a few minutes to several hours for a respondent to answer a set of questionnaires. The question arises, If respondents take more time, does this lead them to modify their answers? Which modifications are likely?

The interviews to be described were motivated by a desire to make the respondents reconsider their answers in order to find out whether the answers adequately expressed their opinions, provided the persons can be said to have had opinions.

Because of limitations of time and resources, not all respondents were asked to review their answers. If some questions were left unanswered or if answers were detected at once as unclassifiables, an appeal to look once more was made. In some groups of respondents, all who gave disconfirmatory answers were asked to reconsider.

The methodological dangers of such checks are obvious: there is always the risk that respondents will be led by suggestibility or social pressure to modify answers in the direction they suspect is desired by the test leader. This they may do, not only to conform to what they think is expected from them, but also because they may escape further work by answering in such a manner. Interview techniques in general are beset by difficulties caused by irrelevant influences radiating from the test leaders, and it is scarcely

practicable to avoid such influences in our tests. What can be done is to test and map out the influences and correct results of questionnaire methods on the basis of our knowledge about those influences.

In the present case, our main, rather limited, objective was to find out what kinds of considerations, if any, were made by respondents who gave answers of the patterns classed as disconfirmations.

The approach of the test leader was as follows:

The respondent would first be assured that there was no mistake in his work, there being no reason to speak of errors, insofar as what was asked for was only how he interpreted certain words or sentences. We had no interest in finding out which were the so-called «correct» interpretations or answers.

The analyst would then go on to explain that answers of various kinds are more or less frequent, and that the respondent's answers fell into those that are infrequent. He would then ask, «Could you please reconsider them, just to be sure that what you have written expresses your opinion?»

Some respondents received the Qs4 and Qsi4 questionnaires by mail. Those whose answers gave negative symmetry or transitivity received a follow-up letter that read:

In the spring of 1951 you were kind enough to answer a questionnaire concerning your use of certain expressions. Questions of this kind are in principle not capable of being answered «right» or «wrong», and there will always be large variations among different people. Certain answers, or rather certain combinations of answers, were, however, so infrequent that in order to be quite sure, I wish to ask you if you would have given the same answer if you were asked today.

I enclose parts of your answers to the questionnaire and hope you have time and patience enough to look it through once more.

In reconsidering his answers, the respondent often asks questions about how the questionnaires are to be understood, what they ask for, and so on. The test leader answers, and may thus bring the interpretation of the respondent nearer to that of the analyst—a process that well might be effectively done by reformulation of the questionnaires.

Generally, the respondent will suddenly say that he has made a blunder: he was not careful enough; or he did not interpret the questionnaire as did the test leader, and thought that T was occurring and then U, and both on the same occasion; and so on. The disconfirmatory pattern is changed

VIII. SYNONYMITY QUESTIONNAIRES IN USE

into a confirmatory (or irrelevant) one without further intervention by the test leader.

In some cases, a respondent discovers that he wrote something he did not mean, or that his formulations are obscure or misleading at certain points and require changes. In the case of Qs4, the expressions «necessary» and «sufficient» condition sometimes gave rise to discussions with the test leader.

In only one case did a respondent feel no need to change anything, exclaiming that «there *must* be a difference» such that $\text{Syn}(T,U)$ but $\neg\text{Syn}(U,T)$. He was disinclined to indulge in time-consuming reconsiderations.

The «reconsideration interviews» resulted in all disconfirmatory cases being eliminated from answers to the (indirect) symmetry questions of the following pairs of questionnaires:

Qsi1	Nos. 1 and 2	10 cases
Qsq1	Nos. 1 and 2	3 cases
Qs2	Nos. 3 and 4	6 cases
Qs3	Nos. 1 and 2	9 cases
Qs4	Nos. 3 and 4	1 case
Qsi4	Nos. 1 and 2	3 cases

In Qs1 Nos. 2.7 and 2.8, one person (mentioned above) did not change his formulations, with the result that of four cases of disconfirmation, only three were eliminated.

In Qs4 Nos. 3 and 4, one person to whom the questionnaire was mailed for reconsideration lost the questionnaire. He filled out another copy. This time the answers were different, but still disconfirmatory, and he refused to spend any more time on it.

Disconfirmatory cases of transitivity, four in all, were eliminated from answers to Qs1 Nos. 2.1, 2.4, and 2.5; Qs4 Nos. 1 and 2; and Qs4 Nos. 3 and 4. No cases of persistence were found. Of the disconfirmatory cases of subsumption theorems (nine cases) related to Qs4, only seven were eliminated; the two remaining cases belong to the above-mentioned respondent who lost the questionnaire.

The same follow-up letter was sent to the persons giving disconfirmatory answers to Qs4 and Qsi4. They all changed their answers, giving now the answer «Yes» to all questions, and therefore there were no disconfirmations.

Nothing prevents the interview technique just described from being codified and added to the Qs questionnaires. Fairly large and complicated

questionnaires would be the result of such an integration. By means of such questionnaires, concepts of synonymy could be introduced that could be defined by reference only to direct answers and that would yield very few disconfirmations to the symmetry and transitivity theorems.

It is in no way suggested, however, that it is practicable to avoid all misunderstandings and blunders; and in the last resort, the analyst's conviction that all cases of disconfirmatory answers are based on misunderstanding or inconsistency or blunders of formulation, may be false. So far, however, no disconfirmatory answers have been found to contain reference to arguments that we deem convincing. That is, the answers do not seem to yield adequate information about usage and interpretation patterns of designations, declarative sentences, questions, or imperatives that are inconsistent with symmetry theorems asserting symmetry of occurrence synonymy.

VIII.8. Empirical Evidence from Metaquestionnaires

If a set of expressions from a Qsxy questionnaire other than its crucial ones are used as crucial expressions in a second Qsxy questionnaire, the latter is called a Qsxy metaquestionnaire in relation to the former.

Questionnaire MetaQs1I

The first metaquestionnaire, here called MetaQs1I or MetaI, answered by only a small number of people, has a rather complicated text that makes it understandable only to people already familiar with semantical questionnaires. It consists of three parts.

Part one is identical with Qs1 No. 2.1, concerning synonymy of «true» and «perfectly certain», except that the sign «U₁» is used instead of «U», and the answers offered to respondents are indicated thus:

«Answer 1: Yes. No. Don't know. (Erase what does not suit you.)»

Part two is closely related to Qs1 No. 2.6, concerning «is true» and «is the case», except that the sign «U₂» is used instead of «U», and the alternative answers are indicated as above stated.

Thus, the first two parts of MetaQs1I are merely a combination of two ordinary Qs1 questionnaires. (These parts were referred to collectively as Qs1, I, No. 1 in the material given to respondents.)

VIII. SYNONYMITY QUESTIONNAIRES IN USE

Part three reads as follows:

You have now answered the questionnaire QsI, I, No. 1. We wish to find out whether it has been formulated adequately. Our doubt regarding adequacy concerns in the first place our formulation of the questions, for example, the question:

«Would U_1 (or U_2) have expressed the same assertion to you as did T when you read T?»

On page 4 you will find a series of interpretations of the question formulation (let us call it S_0). For the sake of easy survey, we suppose the interpretations to have emerged by interpreting four parts of S_0 , namely a_0 , b_0 , c_0 , and d_0 :

a_0	—	would U have expressed --- assertion
b_0	—	the same
c_0	—	to you
d_0	—	as did T when you read T

Suppose that in the questionnaire QsI, I, No. 1 instead of S_0 , you had found a question formulation in which each of the parts [of S_0] were replaced with various interpretations mentioned on page 4 (a_1 – a_4 , b_1 – b_3 , c_1 – c_5 , d_1).

Imagine that only one of the parts of the sentence was exchanged with another, or also two, three, or four, in such a way that all combinations of interpretations of the parts occurred. We are, however, interested only in combinations that make good sense. For example, it scarcely makes good sense to place together a_3 , b_0 , c_4 , and d_0 . In that case, this sentence emerges: «Does U according to customary usage mean the same as T did when you read T?» On the other hand, it makes good sense to combine a_3 , b_0 , c_4 , and d_1 : «Does U according to customary usage mean the same as T?»

Then three questions are put:

Question a: For which combinations of interpretations (if for any) would you have given a different answer than you actually gave under «Answer 1»?

Question b: For which combinations (if for any) would you have given a different answer from that you actually gave under «Answer 2»?

Question c: Which combinations, if any, would not have expressed the same question to you as did S_0 when you read S_0 ?

Question a refers to answers to QsI No. 2.1 in part one of MetaQsII, and question b refers to QsI No. 2.6 in part two of MetaQsII. At the end of MetaQsII («page 4») is found the list of interpretations.

VIII.8. *Empirical Evidence from Metaquestionnaires*

a ₀	would U have expressed --- assertion
a ₁	would U have expressed the
a ₂	would U have meant the
a ₃	does U mean the
a ₄	could U have expressed --- assertion
b ₀	same
b ₁	absolutely the same
b ₂	roughly the same
b ₃	fairly accurately the same
c ₀	to you
c ₁	(nothing)
c ₂	as you understood U
c ₃	as you understood U when abstracting from things you possibly have figured out after having looked into this scheme
c ₄	according to customary usage
c ₅	according to philosophic usage
d ₀	as did T when you read T
d ₁	as T

This list of combination units was followed by a list of examples. Some of the examples are here quoted because our statistics relate to the individual items of the list.

a₀b₀c₃d₀: Would U, as you understood U when abstracting from things you possibly have figured out after having looked into this scheme, have expressed the same assertion as did T when you read T?

a₃b₀c₁d₁: Does U mean the same as T?

a₀b₀c₄d₁: Would U, according to customary usage, have expressed the same assertion as T?

In the list of examples, seven more combinations were given:

a ₀ b ₃ c ₀ d ₀	a ₃ b ₀ c ₅ d ₀	a ₄ b ₀ c ₀ d ₀	a ₀ b ₀ c ₁ d ₁
a ₀ b ₂ c ₀ d ₀	a ₂ b ₀ c ₀ d ₀	a ₃ b ₀ c ₄ d ₁	

VIII. SYNONYMY QUESTIONNAIRES IN USE

It was, of course, not expected that the respondents would report in detail on all 240 combination possibilities. On the basis of previous experience, it was expected that most respondents would at once discard a number of possibilities because they would not lead to a difference in the cognitive contents of the synonymy question, or at least would not lead to different answers.

Main Results

Thirty people gave complete answers. Of these thirty respondents, twenty-nine agreed that if the synonymy question «Would U_1 have expressed the same assertion to you as did T when you read T?» had been replaced by $a_0b_0c_1d_1$, that is, by «Would U have expressed the same assertion as T?» this would not have made them answer differently than they did. In relation to $a_3b_0c_4d_1$, «Does U mean the same as T according to customary usage?», only two changes in answers were recorded. This supports the hypothesis that it makes little difference to respondents whether one asks them about ordinary usage or their own usage.

Also, for $a_0b_0c_3d_0$, only one instance of difference in answer was recorded, but in this case in relation both to the substitution «is true» — «is perfectly certain» and the substitution «is true» — «is the case». The other exemplified combinations were reported by more than one person to cause changes in their answers.

On average, 4.6 persons reported an inclination to change answers if the synonymy question in part one (concerning «true» — «perfectly certain») was changed in the eleven directions exemplified at the end of MetaQsI. The analogous average with regard to part two (concerning «true» — «is the case») was 3.8 persons. Thus, the percentage change in answers attributed to the eleven reformulations was found to be 14.0. The change in formulation that would cause the greatest number of changes in answers by far—according to the respondents—was $a_3b_0c_5d_0$, which included the term «philosophic usage». If that example of change had been left out, the percentage change in answers would have been reduced to 10.8.

Inspection of the kinds of reformulations exemplified at the end of MetaQsI suggests that synonymy question formulations may be modified within wide limits without appreciable changes in answers. *Answers are largely invariant to a great number of modifications.*

The importance of this conclusion lies partly therein, that it warns against using answers as if they were highly specific to a particular interpretation of the question posed, for example, in relation to interpretations that the analyst from general considerations expects to indicate «how the respondents interpret the question».

On the other hand, an assertion that one would answer affirmatively (or negatively) to two question formulations does not furnish much evidence that the formulations were interpreted to have exactly the same meaning. The long series of modifications of question formulations without corresponding changes in answer may be taken to furnish *some* evidence supporting the hypothesis that the formulations were interpreted as questions with only slight differences in meaning.

Questionnaire MetaQsII

MetaQsI asked respondents to consider vast numbers of sets of modifications of the synonymity question—a procedure that invites serious objections on humanitarian grounds. It may also be objected that perhaps some of the respondents did not understand the technique of substitution or that their answers were not based on close inspection of more than a portion of the combinations. It is difficult to check whether respondents have taken their job sufficiently seriously. (The questionnaire MetaQsI was given only to students who were judged to be both conscientious and gifted.)

A new questionnaire, MetaQsII, was designed to make the procedure easier for respondents. Rather than ask them to consider the eleven examples of modifications of the original synonymity question, we used twelve independent questionnaires, in each of which one modification of the original version was formulated in detail. The whole series of twelve—very similar—questionnaires was called MetaQsII. The complicated list of combination possibilities of MetaQsI was left out.

Thirty people went through this set of questionnaires.

Main Results

To what extent do the respondents' answers vary with modification in the formulation of the synonymity question?

The number of respondents who changed their answers when the syn-

VIII. SYNONYMY QUESTIONNAIRES IN USE

onymity question changed was greater than in the case of MetaI. On average, 10.7 persons changed their answers when the synonymity question in part one (concerning «true»—«perfectly certain») was changed in the eleven directions. The corresponding number for part two (concerning «true»—«is the case») was 8.3. The percentage change in answers was 31.7. If the synonymity question including the term «philosophic usage» had been left out, the percentage would have been 26.7.

A Differential Procedure

The technique of asking people how they would react under certain nonexisting conditions has obvious weaknesses from a methodological point of view. To find out a little about the influence of these weaknesses, we constructed a test in which each modification of a questionnaire was handed over to separate groups of people.

Ten of the twelve questionnaires of MetaQsIII were distributed, each to 30 people. No person received two or more questionnaires. Thus, 300 people were involved.

All questionnaires of the group of ten were exactly alike except for the variation in synonymity question. We used the same synonymity questions that were used in the MetaQsII questionnaires, except for the question containing the term «philosophic usage» and one of the questions containing the term «common usage».

Our main interest in what may be called «the differential procedure» is in comparing the results with the results of MetaI and MetaII. We shall, therefore, abstain from discussing the results of this procedure in isolation and proceed to a general comparison.

Comparison of Results of MetaI, MetaII, and the Differential Procedure

This comparison is not without complications, and a fairly complete table is therefore needed. In the second column of table 10, we have given abbreviated versions of the synonymity questions. They can be assembled in their complete form from the combinations indicated on page 473ff. Synonymity question No. 1 is the «standard» used in QsI and in the first two parts of MetaQsI.

From the third column onward, the table is divided into two main

parts, the first related to synonymy questions concerning the pair of expressions «true» — «perfectly certain» and the other to the corresponding pair «true» — «is the case».

The division of each of these main parts into three subparts corresponds to the three procedures. The columns report numbers of changes of answer—with the answers to No. 1, the standard form of synonymy questions, being taken as the point of departure.

Two quantities are calculated to give a picture of changes: one is recorded under «≠» with a «d» added and gives simply the difference between the number of «Yes» answers to synonymy question No. 1 and the number of «Yes» answers to No. 1, plus the difference between the corresponding numbers of «No» answers, plus the corresponding numbers of «I do not know» answers. These sums are not directly comparable to the numbers found as results of the MetaI questionnaire. If, for example, twenty-two people answer «Yes» and eleven answer «No» to both synonymy question No. 1 and synonymy question No. 2, this does not imply that every person has answered the same to those questions. Maybe those eleven who answered «No» to No. 2 answered «Yes» to No. 1, but at the same time eleven of those who answered «Yes» to No. 1 answered «No» to No. 2. This means that twenty-two persons have changed their answers, but without effect on the sums reported under «d». On the other hand, if only one person changes an answer from «Yes» to «No», this results in a difference of two in the sum of differences (≠d column), there being one less «Yes» answer, and one more «No» answer. The number of persons making changes is therefore reported under «≠p» and separated from the number of changes reported under «≠d». (The material obtained with the use of MetaI does not permit us to determine the quantity «≠d»; and from the material obtained by the differential procedure, we cannot determine «≠P».)

One of the easiest things to account for is the smaller number of respondents changing answers and the smaller number of changes in relation to the expression pair «true» — «is the case». All questionnaires used have consistently pointed to a closer similarity of meaning between «true» and «is the case», and more people taking them as synonymous, than that between «true» and «perfectly certain». The higher and more strongly held «Yes» scores of «true» — «is the case» account for many differences be-

Table 10. Comparison of Meta-results

tween results relating to «true»—«is the case» and «true»—«perfectly certain».⁴

The main and most important result is that fewer people say they would change answers than actually change answers: more than twice as many respondents answer otherwise than they actually do to synonymity question No. 1 than declare that they *would* if certain changes were made.

If, now, this comparison between MetaI and MetaII is related to the results of the differential procedure, it is found that the last-mentioned results lie somewhere in the middle between MetaI and MetaII.

Taken at face value, the comparison shows, roughly, that people asked whether they would have given other answers *if* a certain nonexistent condition were realized, *underestimate* the extent to which their answers actually would have changed. Further, people placed in a situation somehow approximating that nonexistent condition and involving answering a number of questionnaires with very small differences in text, tend to react with different answers to these differences more often than under the condition in which they cannot compare closely similar texts.

An «oversensitiveness» to differences presented as they were by MetaII seems simple to explain: each of the small differences in synonymity questions stood out in relief against the backdrop of identical contexts. In MetaI, however, the identity of context was carefully explained to the respondents, yet there was a comparative «insensitiveness» to the differences. It is not so easy to account for the great difference in answers to MetaI and MetaII. If MetaII led to oversensitiveness, why did not MetaI do the same?

One factor that may have played a considerable role was the impressiveness of the effort made in the MetaII procedure to fix the respondent's attention on every single variety of synonymity question. Each variety had its own slip of paper, its own questionnaire. Maybe the respondents were induced to think, «If it is worthwhile to print questionnaires that are identical except for a very small number of words, these must have rather different meanings!» Of course, nothing like this was suggested by the test leader, but nevertheless respondents may have felt an urge to differentiate clearly in their reactions to the different sheets of paper. The questionnaire MetaI consisted of much less paper and was more condensed. This may have given the respondents less motivation to proceed carefully and to react differently to different questions.

VIII. SYNONYMITY QUESTIONNAIRES IN USE

Whatever reasons are considered plausible, the result remains that differences in procedure—exemplified by MetaI and MetaII, and the differential procedure—may yield considerably different answers.

VIII.9. Difficulties of Questionnaire Procedures

In this section, we discuss some of the obstacles that endanger the fruitfulness of the «method of synonymities» (chapter 1, page 14ff.). They are so grave that it is quite natural to think that further use of the method must be viewed as unwarranted from the point of view of scientific method. Our conclusion will be, however, that continued use is warranted, partly because the method has yielded some results of interest and can be perfected, and partly because experience with other methods has convinced us of the very considerable difficulties encountered, whatever avenue of attack is chosen.

General Considerations

The first problem to be considered may be stated as follows: The persons used as test subjects presumably have greater than average intelligence, but they nevertheless succumb to *inconsistencies* in their answers. This may lead to replies being classed as disconfirmations of theorems of QsxA-symmetry or -transitivity.

An interesting example of such a case is the reply of respondent 5 to Qs11 and Qs12. He there entertains the opinion that «it is true» is a statement the validity of which depends on the kind of information available to those who use the expression. Thus, at the time of Holberg (an eighteenth-century Danish-Norwegian author), it was in many cases true that the earth was flat, since the information those persons had, who might have said «it is true that the earth is flat», was of a kind making it justifiable to assert the flatness. Many philosophers and logicians would at once object to the possibility or probability that the respondent «really» uses the expression «true» in this way. I think such an objection a priori is unwarranted, but let us see how this opinion on the part of the respondent influences his further reply.

He says that he uses «it is perfectly certain» independently of the kind of information. Then he infers that from the perfect certainty of some-

thing, the truth can be inferred, but not vice versa. This, he thinks, is the reason that he would interpret the sentence in the text Qs1 No. 2.1 («It is true that ---») to express a different assertion from «It is perfectly certain that ---». He answers «No» to both Qs1 No. 1.1 and Qs1 No. 1.2, but to Qs1 Nos. 1.2 and 2.2 he answers «Yes» (thus creating an instance of disconfirmation of Qs1.9-symmetry). He explains that he so does because *if* something is perfectly certain, *then* it is true.

It was assumed that respondent 5 had (vague) ideas of identity of assertions with which the last-mentioned inference could not possibly be consistent, and subsequent interviews confirmed this. His total reply was therefore not taken as a disconfirmation of Qs1B-symmetry theorems.

The kind of inconsistency to which respondent 5 succumbed may be roughly formulated thus: sometimes it is taken as a sufficient criterion of x being synonymous with y, that if y is true then also x is true; sometimes the same relation is only taken as a necessary condition.

The case of respondent 5 has been reported to stress that respondents certainly are sometimes inconsistent, but that the analyst cannot without very close analysis hope to be able in all cases to distinguish peculiar but consistent replies from inconsistent ones. Analysts tend to overestimate the frequency of inconsistencies. There are more usages under the sun than is suspected by learned men.

The case of respondent 5 also reveals how inferences of a general and highly speculative nature enter into the seemingly easy question about how a person interprets a text he has read, let us say, at most, thirty seconds earlier. Some respondents may be expected to try to arrive at the exact interpretation by taking up the much more general question of how they interpret a certain expression no matter what text it occurs in. In this respect, some of the respondents resemble logicians and philosophers when they answer questions about how they interpret and use the word «true».

Not only factors such as «insufficient» intelligence or general education, limited time and energy, and lack of special knowledge about the theory of knowledge, logic, linguistics, and semantics are to be held responsible for unclear and doubtful answers, but also the nature of the questions asked: nobody today seems to have a theory of interpretation and tools for finding interpretations that would make their answers to Qs1 acquire the status of fairly precise, reliable knowledge. This holds good even more con-

VIII. SYNONYMY QUESTIONNAIRES IN USE

vincingly as regards Qs2 and Qs3. There is, of course, some difference of degree, but basically the students and the specialists in logic and related fields are on the same level.

Difficulties of Qs1

A second problem is that the choice of variable expressions in Qs1—«true», «perfectly certain», «the case»—makes that questionnaire somewhat difficult to answer. Even well-educated generalists have rather vague ideas about the relation «T and U express the same relation». This makes many uncertain as to what to answer; they may find «Yes» and «No» equally justifiable answers. To this are added the particular difficulties, already mentioned, of complex differences in the usage of «true» and «perfectly certain». Out of sheer uncertainty, a respondent may answer «Yes» and «No» in such a way that transitivity of synonymy is denied. The respondents are «inconsistent» in their choice of «Yes» and «No» answers because both answers seem equally justified.

Instead of speaking about inconsistencies, one might in this situation just as well speak of absence of opinions, and define in such a way that a certain degree of stability is required. If the marginal reference, «s», of synonymy relations $\text{Syn}(\text{abps})$ is a reference to a small time interval, let us say, one minute, there would be no inconsistencies because $\text{Syn}(\text{abp}_1\text{s}_1)$ would not contradict $\neg\text{Syn}(\text{abp}_1\text{s}_2)$. Answers given several minutes apart would be referred to synonymy hypotheses with different marginal references.

If the respondents are led to adopt definite criteria of synonymy, some of the difficulties vanish, of course, but in the case of Qs1, this would defeat one of the purposes of the questionnaire: to explore how the term «express the same assertion» is used.

Even in the case of no concept of synonymy being forced on the respondent, the symmetry and transitivity relations of their answers are confirmed, as we have seen (tables 3–7).

Let us glance at the details of a group of twenty-eight replies to the sequence of questionnaires Qs1 Nos. 1.1, 1.2, 2.1, 2.3, 1.4, 1.5, 2.4, 2.5. They all concern Qs1A-synonymy relations between «true», «perfectly certain», and «the case», as described on page 455ff.

Sixteen replies contain only «Yes» as answers to the eight questions.

There is, of course, not much to be learned from such short replies, but we take them as a symptom of symmetry and transitivity of those respondents' (perhaps very vaguely conceived) concept of identity of meaning. We also take the answers as symptoms of how, in a particular situation, those respondents would interpret the expressions and sentences referred to in the synonymity questions.

Six replies contain «Yes» and some comments. Some of the comments belong to kinds that are of general interest. Thus, in the answer «Yes, but ---», is «but» meant to indicate a modified, conditioned answer, an answer with a reservation that makes the reply *strictly to the question asked* a different one from plain «yes»? Or is «but» here only meant to indicate some kind of phenomenon that makes a sort of contrast to the state of affairs affirmed unconditionally by «yes»? Interviews revealed that the second alternative usually holds good, but in some cases, the «Yes, but ---» is meant as a reply different from «Yes. But ---». Some cases are borderline cases.

Three of the respondents with «Yes, but ---» answers said that «perfectly certain» is stronger than «true». Asked to make more precise what kind of strength is referred to, they adopted various directions of precization, some leading to the conclusion that «perfectly certain» and «true» express different assertions, some leading to the conclusion that they express the same assertions.

Two of the respondents with «Yes, but ---» answers stressed that the use of «it is true that ---» is dependent on previously expressed doubt. It is a sort of reaffirmation or affirmation in the face of denials. Interviews showed that the «Yes, but ---» was to be interpreted as «Yes. But ---», not as «Yes, but ---». The answers were taken as a symptom that if those respondents had been invited to use proposed criteria, their answer would have been «Yes. But ---». It is of interest to note, however, that the possibility of «Yes, but ---» is not to be excluded a priori: to some people «it is true that ---» as occurring in the questionnaire might mean «it is doubted, yet true that ---».

The other (qualified) positive answer contains only «without doubt» as a comment.

The «Yes, but ---» difficulty can largely be avoided by supplying detailed instructions about how to separate «Yes, but» from «Yes. But». Such

VIII. SYNONYMITY QUESTIONNAIRES IN USE

instructions cannot but be complicated, however, and may annoy some respondents. The possibility of suggestion must also be taken seriously into account.

Let us leave the «Yes, but ---» complication and inspect the comments made in replies, whether positive or negative.

Of the four persons saying that «perfectly certain» is *stronger* than «true», two gave the already mentioned «Yes, but ---» kind of answer, whereas two answered «No». By subsequent interviews it was established that «stronger than» to some means «having stronger power of persuasion», and this makes the «stronger than» seem irrelevant if our criteria are adopted. In relation to other criteria of identity of meaning of assertions, the persuasive power may of course be relevant. To others, «it is perfectly certain» implies that it is «shown» («proved») to be so, something not implied by «it is true that». This interpretation of «stronger than» seems in at least one case to explain the answer «No, «perfectly certain» is stronger ---».

The most important thing to note in connection with the distinction between 'stronger than' interpreted in such a way that it is relevant to our criteria and interpreted so as to make it irrelevant, is, I think, the complexity of unsolved and even unaddressed questions raised by the respondent when struggling with borderline cases. Of these there are so many that the replies in terms of the distinction «express same assertion versus express different assertions» lose much of their value. There is nothing that suggests that the replies of specialists in semantics (including lexicographers and semanticists in the sense of Carnap-Morris) would be much easier to evaluate.

A third group of difficult comments are those in which it is asserted that one of the three expressions (roughly: true, certain, the case) is *more precise than* the others. Different concepts of «preciseness» are involved, some making the assertions of relations of more or less preciseness relevant to our criteria of identity of meaning, others making them irrelevant.

Concluding, we may say that there are three main special difficulties confronting those who try to classify replies to the synonymity questionnaires Qs1 Nos. 1.1–1.6, and Nos. 2.1–2.6 into positive and negative:

1. the «Yes, but ---» answers,
2. the «x is a stronger expression than y» answers, and
3. the «x is more precise than y» answers.

By means of extra instructions, subsequent interviews, and «metaquestionnaires», the special difficulties have been overcome in most cases, leaving from 3 percent to 6 percent of cases in which classification into positive or negative has been persistently uncertain.

Not all those uncertain cases affect classification of replies into confirming and disconfirming ones of the A-variety. If it is doubtful whether the reply to a pair of questions «Syn(ab)?» and «Syn(ba)?» is positive or negative, we can in most cases say, «If the reply to the first question is interpreted to be positive (or negative), the hypotheses of interpretation used lead to the same conclusion with respect to the second question». Thus, the uncertainty does not lead necessarily to doubtful classification of symmetry confirmations.

Difficulties of Qs2

A third problem affecting the fruitfulness of the «method of synonymities» is that the replies to Qs2 clearly show a source of misunderstanding of synonymity questions that not only seriously lowers the value of the replies to Qs2, but may be reckoned as one of the chief sources of superficial answers to questions of interpretation, whether in the form of questionnaires or otherwise.

Just as in the case of Qs1, the respondent to Qs2 is invited to interpret a text containing T, then to imagine that he has *not* read that text, but one in which U occurs instead of T. The question posed concerns the relation of the interpretation of T and U under the assumption, of course, that there is not one text containing both T and U. It is essential that the respondent not interpret U in the light of T, and vice versa, but independently of each other. Alas, that is exceedingly difficult to explain to most people.

Unhappily, Qs2 opens with T and U appearing close to each other in print. It is inevitable that respondents concentrate their attention on the difference between them, and it turns out that after having seen the sentences close together, many respondents can no longer think about them separated from each other. Additional instructions (see page 404) that explicitly mentioned the source of confusion and warned against it in strong terms, did not always succeed in making respondents avoid the pitfall.

The effect of this confusion concerning contexts, the «natural context»

VIII. SYNONYMY QUESTIONNAIRES IN USE

and the «analyst's context», is dramatically illustrated by the following example.

Suppose we ask some students about the meaning of «year 1949 B.C.» and «year A.D. 1949». Most will answer that the first expression connotes a definite year before Christ and the second a definite year after Christ. If it is then asked what the expression «year 1949» connotes, the previous questions will make some of them answer that it has no definite meaning, because of the scale before or after Christ; the Jewish or Mohammedan scale might even be meant. Some might say that it has a definite meaning, namely «year 1949 after some year or other conceived as year 1». Thus, it might be a class name.

Now, after all this discussion of calenders, we introduce T and U:

T: There was at least one eclipse of the moon in 1949.

U: There was at least one eclipse of the moon in A.D. 1949.

If we ask the students how they would have interpreted these sentences if they had read them in different contexts, and whether they would have interpreted them to express the same or different assertions, they tend to give the answer «*different*». It is plausible for us to suppose that the answers are *misleading*: if the respondents had not had their attention fixed on certain *possibilities* of differences in interpretation, their answers would have been more correct. That is, if the experiment were carried out, and the respondents made to read either T or U in some contexts, let us say once a month, and to list their interpretation without having an opportunity to compare T and U, the result would probably show an overwhelming majority of interpretations of T and U to mean the same assertion.

In the case of Qs2 No. 1 and No. 2, T and U were:

T: Not all numbers below 10 are divisible by 2 and 3.

U: Not all whole numbers below 10 are divisible by 2 and 3.

Many persons must (characteristically enough!) read the sentences twice before they detect the difference in wording. Once they have discovered the difference, the possibility of interpreting T as referring *not just to whole numbers* stands out clearly, and affects their answers to the synonymy question.

VIII.10. Effect of Reversal of Order of Sentences in Qs3

That this really happens was clear from subsequent interviewing. Some of the respondents changed their answer after having conceived clearly the idea of thinking of the texts as separate texts that are not comparable in the natural context, but only in the subsequent context of the analyst.

Because of the difficulty of abstracting from the analyst's context, Qs2 was changed.

The importance of the confusion lies in the circumstance that whenever a person is asked how he would interpret two sentences, the proximity of the two sentences in the experimental situation will affect the reply: the respondent's attention is at once concentrated on the difference in wording and he is led to imagine that this difference will result in different interpretations of the sentences, even in natural contexts in which the sentences do not occur near each other.

The result of the confusion is a vast overestimation of the definiteness of intention: respondents are led to believe that because there is a difference in wording, the sentences will be interpreted differently and in such a way that interpretations correlate highly with each difference in wording.

Another result is to lead respondents to deny that vast numbers of differently worded sentences may be interpreted the same way without there being reason to accuse the interpreters of superficiality in attention to what «really» is said.

Still, another result is a strengthening of belief that there is a literal sense of words and sentences, which is the real and exact sense, the sense in which linguistically careful and conscious people understand the words and sentences.

VIII.10. Effect of Reversal of Order of Sentences in Qs3

The extensive experimentation with modifying the wording of questionnaires has had but one aim: to make the respondent understand what the analyst tries to communicate to him in the questionnaires. Because of the formidable difficulties met with, it has been considered premature to take up systematically another aspect of importance to the questionnaire technique: that of suggestion, of leading questions, and so on.

Dr. Leo Apostel submitted to us a series of notes concerning possible weaknesses of the questionnaires with regard to suggestibility. At least one

VIII. SYNONYMITY QUESTIONNAIRES IN USE

Table 11. Effects of Reversal of Order of Response Choices, Qs3

Order	Response			Total
	«All»	«Some»	«None»	
a, s, n	25	89	9	123
n, s, a	23	50	21	94
Total	48	139	30	217

of his points was considered important enough even at the present preliminary stage of research to warrant a reformulation of the questionnaires Qs2 and Qs3. In those questionnaires, two positive answers («Yes, in all situations»; «Yes, in some but not in all») are listed before the negative answer is put forth. New versions of Qs3 (called Qs3 No. 3b and Qs3 No. 4b) were used in which the order of possible answers was reversed. As is shown in table 11, the change is correlated with a statistically significant difference in the answers given by respondents.

Although one might have expected the order reversal to cause the number of «Yes. In all situations» responses to drop considerably, such was not the case. If the change in answers is attributable to the change in order, the latter has made the respondents less prone to answer «Yes, in some but not in all», rather than less inclined to answer «Yes, In all situations». The change in frequency is highly significant from a statistical point of view, with $\chi^2 = 11.37$.

VIII.11. Effect of Training on Classifiability of Answers, Qs5

A slight modification of Qs5 was used with «Norway is a democracy» as crucial sentence T, and three different formulations representing U: «Norway has government by the people» («*folke-styre*»); «Norway has a form of government by which the total adult Norwegian population is assured an influence on decisions of significance to the society»; and «In Norway, all who are equally gifted have an equal chance to obtain a higher education».

Two groups were tested. One consisted of fifty-five students at the sophomore level; the other, of thirty-one students who had obtained high marks in courses in logic and history of philosophy or were otherwise known to be well versed in these disciplines. The results of the test are shown in table 12.

VIII.11. *Effect of Training on Classifiability of Answers, Qs5*

Table 12. Classifiability and Training, Qs5

Qs5	Less Trained				More Trained			
	<i>Syn.</i>	<i>Not Syn.</i>	<i>Unclas.</i>	<i>Total</i>	<i>Syn.</i>	<i>Not Syn.</i>	<i>Unclas.</i>	<i>Total</i>
T/U ₁	7	19	29	55	6	23	2	31
T/U ₂	8	20	29	57	3	26	2	31
T/U ₃	1	25	29	55	0	29	2	31

The relations of synonymy answers are about the same in the two groups, but there is a tremendous drop in the number of unclassifiable answers in the better-trained group. The questionnaire Qs5, or at least the version used in the experiment under consideration, must be considered inapplicable to the students with the ordinary sophomore training.

Experience with postgraduate students of logic, philosophy, and linguistics indicates that fresh difficulties arise with «overtraining»: answers tend to consist of lengthy comments concerning the questionnaires or of assurances that the respondent cannot answer because he lacks insight into his own usage, or because of related factors. Thus, the percentage of unclassifiable answers tends to decrease with training up to a certain point, and then increase again.

Twenty-nine answers out of fifty-five were unclassifiable in the less trained group (table 12). One might suspect that the classifiable answers, for example, the straight positive or negative ones, were based on a rather superficial understanding of the questionnaire and that the proportions of such answers largely owe to chance factors. There is an interesting argument against this. It is a rather weak argument, but not too weak to be taken into consideration. A comparison of the twelve quantities under the headings «Syn.» and «Not Syn.» reveals a close agreement in percentages of answers between the less trained and the more trained. This is a symptom of resemblance in interpretation, and if the more trained have been penetrating in their interpretations, the classifiable answers of the less trained might be considered to be representative of a satisfactory degree of understanding.

When we do not take up a number of considerations that already have been shown to be important to the questionnaire technique, it is only be-

VIII. SYNONYMITY QUESTIONNAIRES IN USE

cause of the necessity to work with a priority list. Our first grave question has been, Can synonymity questions be formulated in such a way that they are *understandable* to at least some sectors of a language community, for example, undergraduate or graduate students of certain branches of knowledge? Can the intention of the analyst be roughly conveyed to these persons? How about the small sector of the community consisting of professional students (including professors) of language, logic, and philosophy?

Negative answers to these questions are particularly grave because, so far as I can see, logical analysis and semantics are largely carried on by a kind of embryonic questionnaire method, the analyst asking himself about how words are used. His intended public is mostly made up of students, if not himself alone. Occasionally other analysts read his papers, and this normally leads to controversy in which charges of misinterpretation play an important role.

VIII.12. Concluding Remarks

It is tempting to adapt a questionnaire to the specific task it serves and to ignore the question of how to find standard forms such that what can be found out about the efficiency of one questionnaire can be expected to hold with respect to others. When concepts of a rather sweeping character, such as those of synonymity, are introduced in terms of questionnaire techniques, the search for general forms of questionnaires develops into a major concern. The questionnaires used to obtain the material discussed in this chapter are examples of very simple questionnaire forms. The simplicity and the generality have been obtained partly by deliberate neglect of many methodological requirements that at a later stage of research must be considered to be of high priority.

The primary objective of this chapter has been to offer a sample of material collected by use of the simplest questionnaires, and thereby to furnish a basis for an opinion about what can and cannot be performed by means of such questionnaires.

Secondarily, our objective has been to stress, by means of detailed reports about procedures and findings, that if statements of sameness of meanings are considered to be synthetical, one shall, sooner or later, have to connect synonymity concepts with procedures of some kind, and from that

VIII.12. Concluding Remarks

time on, it will be necessary to carry out time-consuming work of a rather unphilosophic kind. If someone should be induced, by imperfections in the works reported on, to make improvements, much will be gained. The important point here is to get out of the deadlock created by too much sophisticated theoretical discussion about subject matters with empirical aspects.

Series Editor's Introduction

Arne Naess — A Wandering Wonderer: Bringing the Search for Wisdom Back to Life

[The pre-Socratics'] attitude, in the main, was genuinely scientific whenever it did not merely embody the prejudices of their age. But it was not *only* scientific; it was imaginative and vigorous and filled with the delight of adventure. They were interested in everything—meteors and eclipses, fishes and whirlwinds, religion and morality; with a penetrating intellect they combined the zest of children.

From this point onwards, there are first certain seeds of decay, in spite of previously unmatched achievement, and then a gradual decadence. What is amiss, even in the best philosophy after Democritus, is an undue emphasis on man as compared with the universe.

Bertrand Russell, *History of Western Philosophy*

When the full scope of Arne Naess's philosophical contribution is examined carefully and placed in context, it will very likely be viewed as one of the twentieth century's most significant and enduring.¹ Naess has made bold and innovative contributions to conventional academic philosophy and social research, particularly in the areas of behaviorist epistemology, empirical semantics and communication theory, scepticism, scientific and cultural pluralism, Gandhi and Spinoza scholarship, normative systems theory (as a general approach for exploring premise-conclusion relations), and the very idea and relevance of total systems (total views in Naess's *lingua*). Perhaps even more significant—although one should not view it as distinct or decoupled—has been his commitment to reconnect philosophy to life experience. This effort is similar to Bertrand Russell's in that it has been particularly pronounced in later life. Naess, however, carries this com-

SERIES EDITOR'S INTRODUCTION

mitment to expand philosophy's sphere of concern to life in general and the Earth. Essential to this endeavor, is the mature Naess's radical initiative to reconceptualize reason expansively, to integrate reason with emotions and feelings *in practice*. In some cases this includes using mythopoetics to make a case or communicate a point.² What makes Naess so special is that even while paddling against the current, he exhibits tremendous optimism and openness, joy, and a disarming, infectious playfulness.

Naess strives to *live his philosophy*. For more than thirty years, he has sought to reshape the philosophical debate by drawing from and building on his previous work to outline a nondualistic, nonanthropocentric philosophy of life that affirms the ultimate unity and interdependence of all living beings, while maintaining their individuality. His philosophy celebrates the Earth's richness and diversity—both cultural and biological. That said, one of the main purposes of the *Selected Works of Arne Naess* (SWAN), however, is to provide you, the reader, with the resources to make your own informed judgment regarding the significance of Naess's philosophical legacy.

At age ninety-two, Arne Naess has lived a long life filled with wonder. In his words, he has “seen life”—traveling the world, spending significant periods of time on every continent. He has experienced the world somatically and intellectually in concert as one mind-body—as a being—and seen more than most of us can imagine.

When Naess was born, Archduke Francis Ferdinand was alive, automobiles were in their infancy, and most homes did not have running water. Home refrigerators had just begun to be produced. Television and computers were only imagined. Only a few years before, after being contemplated for millennia, the first controlled and sustained powered flight took place, ushering in a period of ever-accelerating transfer of materials and information, but not necessarily a commensurate increase in knowledge or wisdom.

Consider that Naess has lived through two world wars (and too many “limited” conflicts to count), the rise and fall of the Soviet Union and East Germany, the “liberation” of India and Pakistan, the onset of climate change, and the hastening of “global terrorism.” He has been the beneficiary of tremendous medical advances and unprecedented economic growth, and he has seen the ravages caused by escalating consumption, globalization, and disparities in both income distribution and access to resources. He is part and product of humanity's largest growth spurt. And he has witnessed the most significant loss of cultural diversity and the onset of

what may become the planet's greatest extinction crisis—but is surely the greatest extinction crisis ever caused by one of Earth's own species. Naess has also seen and, at times, participated in the many hopeful responses to these ills—the peace, social justice, and ecology movements; nonviolent actions to support antiglobalization efforts and protest dam building; voluntary simplicity; conservation biology; wildlands philanthropy; bio-regionalism; green business and architecture; ecological design, economics, engineering, and restoration; and sustainable agriculture, forestry, and fisheries management.

Everyone is influenced by the times and events of his or her day. The “prejudices of our age” filter into our lives and work more or less consciously and actively, but at a minimum they enter passively. What is the mature Naess's approach to philosophy, how is it a uniquely self-aware and responsive product of his day, and why should it be seen as monumental?

Naess likes to see himself as a “philosopher of life.” The thought of simply being an academic philosopher—living a life of the mind—makes him restless and uneasy. For Naess, “wonder” is both the point of departure for philosophy and the focus of the enterprise. He is the philosophical equivalent of a hunter-gatherer using his wits and intuition to seek out food (for thought) in a fecund landscape. As they were for the ancient Greeks, science and philosophy are inextricably intertwined for Naess. Science, as the application of reason through empirical investigation, cannot be separated from rational reflection on the nature of reason, and vice versa. For the mature Naess, though, philosophy and science are also distinct. Philosophy is the unique realm in which we take up the deepest, most profound, and most fundamental problems. From Naess's vantage, which defines philosophy openly and discursively, the questions that have fascinated and plagued people for millennia have not changed much and they are not likely to change significantly in the future.

Naess's view of philosophy includes the traditional epistemological question “What can we know?” and the ontological question “What main kinds of things are there?” But it also includes “How do we measure?” and “How do we know?” as well as “What is the relationship between the knower and the known?”³ These are questions that are likely to vary with cultural and social circumstances, but this does not, for Naess, imply cultural relativism. By its nature, this view of philosophy runs counter to the dream of the logical empiricists; it cannot be restricted to investigations of

SERIES EDITOR'S INTRODUCTION

“fact” or “logic.” It is imbued with fundamental valuations. Being a philosopher, for Naess, is thus a deeply personal and intimate matter that requires us to engage all of our powers and experience. It should also include questions such as “What are your aims in life?” and “What’s driving you?” as well as encourage a practice of deep and open argumentation by asking repeatedly, “Why do you hold that *p*?” in order to unearth underlying premises and hypotheses. For Naess, all these questions have an empirical component. He sees it as a duty for a philosopher to extend research into the creation and use of empirical methods to address these aspects, unless these questions can be adequately addressed by an existing empirical science, in which case it is fine for a philosopher to perform research here, but it no longer constitutes a *duty*.

In Naess’s view, philosophy is ultimately concerned with how *we*, through our experiences, perceive the world, the world’s relation to ourselves, and the basic features of the condition of people. It is the realm in which we pose sophisticated questions to address perennial problems, probe them from different angles (in Naess’s case, from as many angles as possible), and test and apply the insights to real life—to what we do and decide every day. Its purpose is not to arrive at definitive answers. The purpose of philosophy, rather, is to help us understand what *we* believe in from our innermost perspective, expand this perspective continually, and facilitate communication—so that we might contribute toward improving the state of affairs of the world.

While initially attracted to Bergson’s *les données immédiates de la conscience* (the immediate data of consciousness), Naess grew disenchanted when he recognized that one becomes lodged in an endless circular loop and never exits consciousness. Naess clearly believes that the unexamined life is not worth living (his life is a testament to Socrates’ edict), but he appreciates that disembodied, introspective examination comes at great peril. A mind-centered focus on “examination”—where subjects exist separately from objects, theory is isolated from praxis, and knowledge is decoupled from wisdom—very quickly degenerates into meaninglessness. Worse yet, separating people from and raising people above nature and the coevolutionary process that created us—and provides for our sustenance—can be inimical to life and the evolutionary process.

Nature, that which is, the reality of the pre-Socratics, is Naess’s philosophical palette, not the “world” of his own consciousness as has become

the norm with so many contemporary philosophers since Descartes. Popper and others posit the existence of three worlds that correspond to the development of our commonsense view of reality. World I is the physical world, the "external world," the world of our sensory impressions. World II is the world of all conscious experience, the psychological world of the "immediately given," which incorporates our feelings and intentions. World III emphasizes the logical content of reality. Naess finds these multiple views of reality unconvincing and potentially dangerous. With a worldview inspired by Spinoza's *Ethics*, he is fundamentally opposed to the notion of multiple worlds.

Naess's mature philosophical approach and contributions are shaped by full engagement with a relational reality, in which no firm subject/object, substance/property, universal/particular, fact/value dualities exist. John Muir's famous, deceptively simple aphorism sets the stage: "When we try to pick out anything by itself, we find it hitched to everything else in the universe." Reality as we experience it, according to Naess, is a dynamic, multilayered manifold of hierarchically related gestalts—of which we are always a part. It is the opposite of atomism. Contrary to the dominant, Western way of viewing reality, there are no extrinsically connected discrete objects or "things in themselves" in the sense of Kant's *Ding an sich*. With Naess's "gestalt ontology," there is no dualistic "I" standing outside of reality looking in. Living beings, individuals in the sense of Spinoza's modes, are spatiotemporal manifestations of "one substance," nature or reality. As Naess points out in *Freedom, Emotion, and Self-Subsistence* (SWAN VI), Spinoza's medieval terminology of substance, mode, attribute, God, and Nature is dispensable. In addition, Naess goes on to characterize "living beings" broadly to include individual organisms as well as ecosystems, rivers, mountains, and possibly Earth (Gaia).

Naess's view of reality calls for a gestalt shift. His gestalt ontology does not stop with gestalt psychology's simple notion of holism, where the whole is more than the sum of the parts. It goes on to add that the internally related subordinate gestalts are themselves more than mere parts. There are no parts as parts or wholes as wholes; higher-order wholes are not reducible to lower-order wholes. The concrete contents of reality have gestalt character. For Naess, we experience reality spontaneously and our experience of the world is made up of gestalts. "[This] is the world we experience. Nothing is more real."⁴ People create abstract structures to reflect

SERIES EDITOR'S INTRODUCTION

on or analyze spontaneous experiences and their structure; they are the interrelations between spontaneous experiences. Mind and body are mental contrivances and conveniences—abstract structures in Naess's parlance—for helping us to describe, model, or understand certain states of affairs. They are not the contents of reality. Only individual occurrences of spontaneous experience make up the concrete contents of reality.

What are the consequences of Naess's "ontological realism" as expressed in the form of gestalt ontology? First, living organisms have different levels of access to reality, based on their capacities, experiences, and backgrounds. This implication of "reality is one" plays a central role in the mature Naess's approach to philosophy of science. One of his main thrusts is to undermine the claim that the exact physical sciences show all that is, that they have a privileged view of reality. In his view, science creates extremely abstract structures of what is real, but those structures do not actually *describe* any of reality's concrete contents (descriptions are themselves normative). Jakob von Uexküll, the famous ethologist of the early twentieth century, whom Naess read closely in his youth, helps clarify this notion. "As the spider spins its threads, every subject spins his relations to certain characteristics of the things around him, and weaves them into a firm web which carries his existence."⁵

Different people experience reality differently, yet we often, incorrectly, speak of *different realities* as if they existed. By the same token, identical accounts of reality in no way imply verification of that view by correspondence; from Naess's perspective, such accounts by themselves are merely a sign of cultural poverty. "God" could have created the Earth and life 6,000 years ago, but the evidence to support this case is thin and the evidence to support evolution is stronger, in part because biological science and paleontology generally employ a greater level of depth of intention and thus aspire to maintain higher standards for the evaluation of evidence. Radical pluralism and scientific possibilism do not imply scientific or ethical relativism.

There are at least four other key implications of Naess's gestalt ontology. First, the existence of one, interdependent reality tends to curb solipsism. Second, the world we live in spontaneously can no longer be characterized as merely subjective. Expressions such as "the social construction of nature" become oxymoronic. Third, individual organisms exist as knots in a biospherical web or net. Reality is not anthropocentric; it is not particular

SERIES EDITOR'S INTRODUCTION

to humans. Fourth, humanity can no longer justifiably be seen in opposition to a separate object—nature. This insight tends to temper any “natural” tendencies toward anthropocentrism. As with Leopold’s Land Ethic, people become plain members and citizens of the biotic community, albeit ones with unique powers and proclivities and thus special responsibilities. We are all individual beings, yet we vary in the extent to which we are integrated into the whole.

Humans are massively altering the gestalt character of reality, diminishing it, making it less complex. We do this, Naess argues, without necessarily recognizing we are doing it or the extent to which we are doing it. Thus, we are unable to evaluate the tradeoffs of making such decisions. Naess argues that we generally act simply according to how we “see” reality, but there are aspects of reality that may not be available to us. These aspects are no less there because they are currently unavailable to us, yet they can be destroyed very easily. Sometimes we also confuse our abstract structures of reality (models, data, concepts, etc.) with the contents of reality and vastly underestimate the complexity of internal relations between gestalts, leading ourselves to believe, incorrectly, that higher-order wholes can be reduced to lower-order wholes. It is Naess’s hope that by embracing gestalt ontology, we are encouraged to cultivate our opportunities and faculties for experiencing reality more fully—for experiencing more complex, higher-order gestalts. It is also his hope that we will openly and more carefully consider, in advance, how a proposed research program, action, or decision might affect other peoples’ (or other life-forms’) opportunities for rich spontaneous experiences (consider, for example, the possible impacts of ostensibly beneficial research on nuclear fission or molecular biology). In the end, however, we should remember Naess’s own caution—his description of gestalt ontology is itself an abstract structure. As Naess says, “For me reality has always been something slippery to handle. I seem to grasp it firmly, but like an eel, or even a small lively trout in shallow water, firmness of grasp does not guarantee against escape.”⁶ But does reality really have gestalt character?

Truth—as in *the* truth—is not a defensible notion for Naess. For too many academic philosophers, wonder has been extinguished and replaced by a belief that definitive answers have been found, that the original, initially vexing questions can be laid to rest. Naess is under no such illusion. He views humans as essentially fallible and he sees this domain of fallibility

SERIES EDITOR'S INTRODUCTION

as extending to mathematics and formal logic. This may be why he so freely returns to previously explored material (sometimes just after writing it) and looks at it afresh, with new and frequently competing and even conflicting insights. For Naess, truth is something we seek continually without expecting or believing that it can be found. He seeks peace of mind (*ataraxia*) by suspending judgment (*epoché*). While necessity requires him to take firm positions in life, he often resists taking such positions in his written philosophy. Having reached a general state of mental suspense (*isothenia*), he prefers, as a mature sceptic, anticipating his own tendency to come up with counterarguments and counter-counterarguments, to suggest alternative paths, inspire new ways of looking at things, and foster informed, open-minded debate. This *zetetic* inclination, although nascent in many of his earlier works, was made explicit and became a central theme in his philosophical writings in the 1960s.

For Naess, passivity has no place in philosophy or life. In his famous debate with Sir Alfred Ayer, Naess defines Spinoza's *amor intellectualis* as a "kind of loving attitude towards what you have insight into, while considering it in an extremely wide perspective."⁷ For the mature Naess, *amor intellectualis* involves using his technical and intellectual training to articulate, in direct and forceful ways, his attitudes and evaluations on matters of practical consequence. Like Spinoza and Gandhi, Naess is concerned with human salvation in this world, but Naess, with his concept of "wide-identification," expands this concern to both humankind's relationship to life in general and the self-realization of all life-forms for their own sake. Whether it be understanding how lay people conceptualize truth or experts characterize democracy; considering how our approach to science not only shapes how we do science, but the nature of scientific outcomes too; using philosophy to improve practical communication; facilitating thoughtful debate on the potential dangers of Norway joining the European Union; or discussing the ethics of climbing, the meanings of sustainable development, or distinctions between different approaches for addressing the ecological crisis, Naess seamlessly connects philosophical questioning to activeness in relation to the questions.

Naess's philosophical career can be seen, in one sense, as an attempt to bridge C. P. Snow's two cultures. Believing that the central questions of philosophy are here to stay, he has developed his philosophy over seventy years in part through his effort to relate these questions to the issues of his

rapidly changing, trying, and tumultuous era. Naess's lifelong commitment to integrate interests in nature, science, and logic is evidenced by the mature Naess's championing of philosophical approaches in which both metaphysics and science contribute to all-embracing systems of thought. This approach is particularly prominent in Naess's development of normative systems theory, a strategy for promoting systematic reflection on premises and conclusions. Recognizing that all philosophical questioning must stop somewhere, Naess calls the essential intuitions that serve as bedrock assumptions for our total views, ultimate norms or ultimate premises. Further, recognizing that our philosophical conclusions as well as our lifestyles and everyday actions often appear inconsistent with these ultimate premises, Naess has developed a strategy for using premise-conclusion strings to help identify potential norm conflicts as well as to help assess whether potential agreements and disagreements are real or pseudo. Use of this technique figures prominently in Naess's approach for improving communication, in his approach for exploring both the philosophical basis for Gandhi's *satyāgraha* (active nonviolent resistance) and the Gandhian premise "Any human conflict can be justifiably resolved through nonviolence," as well as in his own Ecosophy T.⁸

With regard to total views—broad philosophical systems like Spinoza's, which attempt to communicate our deepest insights and communicate views of life—Naess argues that although the existence of complete, explicit total views is absurd, it is equally absurd to presume to criticize a total view without adopting one (at least implicitly). After relinquishing the possibility of creating a consistent empirical theory of knowledge, Naess came to believe that any theory of knowledge presupposes all major philosophical disciplines, at least on the metalevel. One cannot have a theory of knowledge without presuming a particular reality, at least implicitly, and this necessitates having an ontology, metaphysics, ethics, and so on. This has practical consequences too. We never simply act solely as a philosophy professor who specializes in logic or ethics; we are always, at least partly, mother, daughter, lover, scientist, . . . , and philosopher. If we accept the premise "For every decision we, explicitly or implicitly, take all things into consideration," then the notion of total views or total normative systems can be seen as very "useful fictions," which, if articulated, might help us to improve decision making.

Naess is careful to point out that he sees his own total view and others

SERIES EDITOR'S INTRODUCTION

as fragmentary and constantly evolving—ever “on the way.” Moreover, even if we could have a completely formed and integrated total view, we could not count on being able to articulate it. There will always be a tension between the Spinozistic goal of clarity and the pragmatic reality that in this world we can never wait until all the facts are in. None of these issues, however, justifies abdicating our responsibility to try to articulate our own total views. The mature Naess is a radical pluralist. He believes in defending coherent systems, without claiming that their relation to reality is definitive. While he is committed to the importance of models and systems, he is opposed to the idea that there could or should be a definite worldview. Naess's hope is that there will be no definite scientific worldview in the future.

No Western philosopher since Descartes—except perhaps Spinoza, who has also been a primary inspiration for Naess—has had the potential to help us drastically reshape our relationship to each other and life in general: not by spelling out *a* clear and coherent total system—to be taken as *the* truth—but by challenging us to articulate our fragmentary total views and connect the abstract problems of philosophy to issues of contemporary social and political conflict. In Naess's view, “[t]he full meaning of a theory can only reveal itself in practice, and practice is blind without theory.”⁹ To be a philosopher of life, one must embrace both theory and practice and engage them in dance.

In Norway, Arne Naess is regarded as a national treasure, a seeker and a seer, a “minor prophet,” in his own words. His radical pluralism and endorsement of diversity are demonstrated by his complex character. He has a proclivity for being aloof and charming, somber and joyful, accountable and carefree, arrogant and modest, slippery and precise. In a world of contradictions—breathtaking beauty *and* ineffable squalor and suffering—Naess is no exception. He is an antiguru guru. He strives for high levels of consistency and integration in his philosophy but accepts that in his personal life he cannot live up to his philosophical systems' requirements. He strives for definiteness of intention, yet he appreciates vagueness and eschews dogma, refusing to be pinned down to a particular viewpoint or placed in a particular philosophical camp. This stance is further supported by his sometimes maddening tendency to revise, revise, and re-revise. As a consequence, one cannot go to any of his books or articles and find the “definitive” Arne Naess. He is a

troublemaker too, but the kind of troublemaker people want to have around because he challenges orthodoxies with an elfin irreverence. Naess stands out because his frequently outlandish and controversial views are felt deeply, reasoned carefully, and conveyed playfully.

Naess has had a profound influence on Norwegian academic life and the society as a whole. From 1939 to 1954 he was Norway's only professor of philosophy. He was chiefly responsible for organizing courses for the *examen philosophicum*, introductory examinations in logic, methodology, and history of philosophy that an entire generation of undergraduates (roughly 100,000 people) were required to take, regardless of their disciplinary focus. His unique paradigm of inquiry—emphasizing open-mindedness, empirical analysis, pluralism, a thorough grounding in philosophy and the history of ideas, and a vital concern for contemporary problems—is credited with shaping the intellectual fabric of postwar Norway. At a press conference for Naess's eightieth birthday, the Norwegian Minister of Education testified to the significance of the Norwegian version of Naess's *Communication and Argument*, one of the primary texts for the *examen philosophicum*. "We have all read it. We *still* cheat in argumentation, but now with feelings of guilt."¹⁰

Naess is also credited with rekindling the study of philosophy in Norway and with forming the Oslo school of philosophy. The section on Scandinavian philosophy in *The Encyclopedia of Philosophy* elaborates:¹¹

The philosophical milieu in Norway today [circa 1967] is determined by an internationally known and original philosopher. . . . Arne Naess . . . is the originator of a radical type of empirical semantics and the leader of the so-called Oslo group. . . . The empirical methods applied by the Oslo group employ carefully worked-out questionnaires. By the help of such questionnaires and by teamwork, philosophers of the Oslo group have carried out investigations of such expressions as "truth," "democracy," and "private enterprise." . . . If it is correct that Norwegian philosophy has had a dead period,¹² it is equally correct to assert that, primarily because of Arne Naess, Norwegian philosophy is now in the middle of a period of life and growth.

When asked to comment on this passage, Naess was emphatic about inserting an addendum to the last sentence.¹³ He was proud to convey that contemporary Norwegian philosophers pursue a wide variety of directions and employ a diversity of approaches, many independent of Naess's own line. This point is borne out by the more than forty-four permanent teaching positions currently at the University of Oslo's Institute of Philosophy

SERIES EDITOR'S INTRODUCTION

and the broad spectrum of approaches these philosophers pursue, from the analytic tradition to phenomenology and from existentialism to hermeneutics. As one of Naess's successors, Alastair Hannay, in his section on Norwegian philosophy in the *Oxford Companion to Philosophy*, has commented, "Norway enjoys a varied and vigorous philosophical life. . . . Philosophy's place in Norwegian academic life, as in the society at large, is due in large measure to Naess."¹⁴

The reach of Naess's contributions to philosophy and social research extends well beyond Norway. Significant international recognition has also come his way for these contributions. He has received the Peer Gynt Prize awarded by the Norwegian Parliament (2004), the Nature and Environment Prize from the Nordic Council (2002), the Nordic Prize from the Swedish Academy (1996), the Mahatma Gandhi Prize for Non-violent Peace (1994), and the Sonning Prize for contributions to European culture—Denmark's version of the Nobel Prize (1977). He has even been honored by five festschrifts, one each for the occasions of his seventieth, eightieth, and eighty-second birthdays and two for his eighty-fifth birthday.¹⁵ He is the founding editor of the influential journal, *Inquiry*, created to promote collaboration between philosophers and social scientists. He is also a renowned mountaineer and climber, an occasional nonviolent political activist, and father of the deep ecology movement. His social concern, sense of wonder, and trickster nature have all contributed to his success at numerous academic posts around the world—preferably near mountains or deserts—from Berkeley to Jerusalem and Helsinki to Hangzhou. He is, to this day, still a frequent international speaker.

Even with this high level of accomplishment, the significance of his work as a whole—as a gestalt—has yet to receive broad-scale appreciation outside of Scandinavia. There are many explanations for this situation.

The overarching reason has likely been the general inaccessibility of his oeuvre. This inaccessibility has many facets. Naess has been incredibly prolific, producing over four hundred publications, more than thirty of which are books. These publications span topics from argumentation theory to zeteticism, with adventures along the way at such seemingly incongruous destinations as climbing ethics, cultural anthropology, and deep ecology. His range of topics—in abundance, breadth, and depth—is trying, at best, for our increasingly compartmentalized and specialized academic communities.

In addition, the bulk of his most significant works have been out of

SERIES EDITOR'S INTRODUCTION

print for quite some time. Many of the earlier editions of the books were edited poorly and documented sparsely. A significant portion of his important articles and book chapters appears in obscure or difficult-to-find books and journals, and much of his work has remained unpublished (at least two hundred papers and several book-length manuscripts). Naess's main works appear in three primary languages, German, Norwegian, and English, although he has also written in Danish, Swedish, and French. Finally, Naess's prose can be dense and opaque, if not downright confusing. Although this trait is by no means unusual for a philosopher, when blended with Naess's appreciation for vagueness and ambiguity, his aversion to authoritative stances, and his tendency to revisit topics by reconsidering earlier viewpoints, the already high entrance fee can become prohibitive.

The boundless range of Naess's interests and the general inaccessibility of his entire oeuvre have led some scholars to view him rather pejoratively as a dilettante. Some of these critics view him as flitting from one area of interest to another, not mining any to its logical conclusion; some see him as throwing away a great talent in logic; some view his social research, especially his work with questionnaires on lay people's and experts' perceptions of philosophical concepts and his use of statistics, as outside the realm of serious, professional philosophy; and still others see him as inappropriately conjoining his philosophy with activism. His breadth has even led a few of the more extreme critics to dismiss his work out of hand. Although some of the criticisms detailed above do have merit, in my view Naess gives the dilettante a good name.

To address this range of concerns, the *Selected Works* project was conceived. The project was the brainchild of Douglas Tompkins. "Miracle Doug," as Arne refers to him, is the founder of the Foundation for Deep Ecology and is himself a renowned climber and kayaker in addition to being a wildlands philanthropist who has helped protect immense tracts of land in Chile and Argentina, some as large as Yosemite. The *Selected Works* would have simply remained a "great idea" without Doug's generosity and support. The project was initiated in 1994 and commenced editorial work in 1996 under my direction.

In the introduction to his *Four Modern Philosophers: Carnap, Wittgenstein, Heidegger, and Sartre* (1968), Naess decries the condition whereby the philosophical life of an individual is set by the local philosophical scene, by provincial biases, or by what is easily accessible.¹⁶ Such accidents of envi-

SERIES EDITOR'S INTRODUCTION

ronment should not, in Naess's view, play a pivotal role in shaping a budding philosopher's development. I see the *Selected Works*, at least in part, as a response to this predicament.

The purpose of the *Selected Works* is to bring—for the first time—the full scope of Naess's philosophical contributions to the English-language audience in one collection of highly readable and meticulously edited volumes that adhere to the highest standards of contemporary academic philosophical publishing. The *Selected Works* is, however, by no means exhaustive; it is not a collected works.¹⁷ We have simply aspired through careful selection to offer a representative and relatively expansive collection of Naess's principal writings. As such, the *Selected Works* is the definitive repository of Naess's oeuvre, chronicling the development and progression of his thinking for scholars, students, and critics alike.

In the remainder of this essay, I attempt to sketch briefly one possible version of an intellectual biography for Arne Naess. I endeavor to trace some key influences on Naess's philosophical development, discuss the evolution of his philosophical outlook, and touch on the relevance and significance of each volume in the *Selected Works*. I close with a short note on our editorial approach.

From Scientism to Wisdom: Toward a Philosophy of Life

The philosophic researcher should be task-minded, not discipline-minded,
and should follow his questions wherever they lead.

Arne Naess, "Norway"

Arne Dekke Eide Naess was born in 1912 in the dining room of a large house with a wild, expansive garden. The house was on the outskirts of Oslo in Slemdal, a short walk from where Naess lives today. Arne was the unplanned fourth child of a wealthy family from Bergen. Before he was a year old, his father, who was ill with cancer, had died. Overwhelmed, his mother, Christine, entrusted little Arne to the family's governess. This is where his first memories begin.

Arne speaks of Mina, his governess, endearingly. She is described as satisfying little Arne's every wish, be it procuring live flies for his bath or bringing a trunk filled with bottles on a family trip so that he could continue his water-play experiments. Sometime before Arne was four, Christine dismissed Mina, ostensibly for spoiling Arne too much. This initiated a deep

rift between Arne and his mother, which was never to be mended. It also set in place a sense of loss, alienation, and resistance to emotion that profoundly influenced Naess's early personal and philosophical development.

Significantly later, after an intensive six-day-a-week, fourteen-month psychoanalysis with Freud's noted collaborator Dr. Edvard Hitschmann, Naess came to understand his impenetrable shell that keeps others at arm's length (*Panzercharakter*, in Freudian terms) as resulting from a reaction to his mother's unreliability and emotional hysteria. His effort to keep his mother at a distance morphed into a general aloofness and distancing. The adolescent Arne began to favor an "objective," bureaucratic approach to language. He saw art, music, and poetry as being seduced by emotion, by beauty and form, but viewed science and philosophy as realms from which such emotions should be banished. This prejudice would take decades to overthrow. At this time he also developed a single-mindedness and resistance to inconvenience and pain that to this day make it easier for him to concentrate and focus. As Hitschmann pointed out, however, this inward turn has a flip side, a certain self-destructive or masochistic bent that was later to plague him, particularly in his relationships with women and his children.

Much of Arne's early childhood was spent at the seashore, and this is the period in which his interest in nature and experimentation began to flourish. Feeling somewhat distanced in his relations with people, he identified with nature, especially little sea creatures. He waded in shallow water for hours, inventing experiments to test nascent hypotheses about the behavior of small sole, tiny translucent shrimp, and crabs. He describes these experiments as engendering an early enthusiasm for diversity and a tendency to suspend judgment on the nobility or status of different beings. He loved these creatures for their unique qualities and their amusing adaptations and limitations. They inspired a certain egalitarianism, which took hold and later influenced his philosophical approach in profound ways.

Young Arne was restless. He had an early penchant for "collecting" and organizing large groups of numbers, stones, and stamps. He started climbing trees in the family's little "wilderness" before he was five and soon progressed to big firs and spruces. He found that he enjoyed being able to watch people from above. Arne outgrew trees fast. His desire for perspective and the opportunity to survey broad areas was rapidly transferred to mountains. At the age of five, he began going to his mother's small moun-

SERIES EDITOR'S INTRODUCTION

tain cottage in the town of Ustaoset, high in the Hardangervidda between Oslo and Bergen. By the age of eight, he had adopted Hallingskarvet, a bread-loaf-shaped mountain about three and a half hours' walk from Ustaoset, as his surrogate father. In his teenage years, this obsession for expansive perspectives translated into a lifelong passion for mountaineering. When Naess was sixteen or seventeen he climbed the 106 tallest mountains in Norway. It was around this time that he was first introduced to Spinoza's *Ethics* by a Norwegian Supreme Court justice that he met in the mountains. Naess's desire for a broad and open perspective, for seeing things in totalities (god's-eye view), translated to his studies. Young Naess read widely in economics (especially value theory), science, philosophy, history of philosophy, and the Earth's biological history.¹⁸ This commitment to cultivate an ever-expanding perspective would later potently influence his approach to philosophy.

Arne's youth was spent captivated by piano, study, and mountains. His decade-older brothers took it upon themselves to toughen up their timid younger brother, as well as introduce him to the ways of the world and scholarship. When Arne was only eight, his eldest brother, Ragnar, left for America to study for a Ph.D. in chemistry at MIT. Ragnar later went on to receive one of the Harvard Business School's first degrees and became a successful stockbroker in the United States. Erling studied economics and went on to create an international shipping empire; he became famous for his assistance to the Norwegian government-in-exile during the Nazi occupation. His sister, Kiki, married a German doctor and after the Second World War returned to Norway to become a physical therapist. From Kiki he learned the power and significance of offering encouragement to others. During his early years and well into adulthood, Arne's tight-knit relationship with his siblings provided security and support for him to "find his own way" — *sva mārga*, to use one of his favorite Sanskrit terms. Although he tended not to seek their financial assistance, his wealthy and generous brothers offered a sense of comfort, safety, and the occasional extravagance, which in later life made it easier for him to live his bon mot, "simple means, rich ends."

Naess studied philosophy, mathematics, and astronomy at the University of Oslo. At nineteen, after completing the equivalent of an undergraduate degree, he left Oslo to continue his studies in Paris. Naess was put off by the adoration Bergson received in Paris, but ultimately left to seek

broader vantage points, cheaper living, and better climbing opportunities. After completing two master's theses at twenty-one, one exploring discussion about the concept of truth and the other exploring the use of behavioral psychological principles to judge truth validity, Naess left Oslo again, this time for Vienna. In Vienna he took master classes in piano, where, following his trickster nature and as a response to the strict taskmaster Fuchs, he "learned" new material. When he ran out of pieces he had long since mastered, he quit. Thinking that it was necessary for philosophers to have high levels of self-knowledge, he underwent intensive psychoanalysis with Dr. Edvard Hitschmann. As a part of that process he assisted with the treatment of patients in a psychiatric hospital and developed tremendous empathy for the suffering of humankind. While in Vienna, he was also warmly welcomed at the famous Schlick seminar.

The logical empiricists' friendly, equiminded approach to discussion made a great impression on Naess, but he was not equally affected by their ideas.¹⁹ The young Arne was impressed by the preciseness, empirical nature, and lack of emotion in science—he wanted to practice philosophy with a scientific bent and he wanted to test philosophical hypotheses with experiments. He was already interested in perennial philosophical problems and did not believe that most of them were ultimately pseudoproblems that could be solved by investigating inconsistencies in language. His most significant philosophical issue with the logical empiricists was not that they were empirical, although he believed they were misguided in thinking that any philosophical problem could be wholly empirical, but that they were ultimately antiempirical in their belief that a logical grammar of language was more suitable for investigating the use of terms than statistical analysis of their actual use. Naess's detailed critique of the logical empiricists' position and reflections on his personal experiences attending the Schlick seminar appear in volume VIII. In this critique, Naess expresses a concern that in their interpretation of terms, many philosophers (not just the logical empiricists) were artificially constricting the range of possible interpretations and thus unintentionally reducing potential insights regarding the diversity of tenable positions on problems of vital concern. This perspective presaged his later views, particularly those expressed in *Interpretation and Preciseness* (SWAN I), and his later approach to cultural anthropology and philosophy of science. Naess sums up his general perspective on the state of philosophy at the time with the following remark: "The

turn of (Western) philosophy in [the twentieth century] towards language rather than cosmos, towards logic rather than experience in the broadest sense (like that of William James), is a turn into a vast blind-alley."²⁰

While in Vienna for fourteen months in 1934 and 1935, Naess made final revisions to his doctoral thesis, *Erkenntnis und Wissenschaftliches Verhalten* (Knowledge and scientific behavior).²¹ Although Naess drew inspiration early on from Russell and Whitehead, his doctoral thesis can be seen, in part, as support of the American Pragmatists (James and Dewey) in opposition to Russell and early Wittgenstein. According to Dewey, the main purpose of his philosophical writings was "to reintegrate human knowledge and activity in the general framework of reality and natural processes."²² Naess did just this by creating a radical and unique approach for exploring how high science is performed, a sort of science of science. At this point, Naess believed it was possible to use such an approach to obtain a complete account of all science within one system. Inspired by the ethologist Uexküll's "special biology" (*Umweltforschung*), Tolman's "objective" behavioral psychology ("molar" behaviorism), and the cultural anthropologist Malinowski's work on speech and nonverbal behavior, Naess took on the standpoint of a neutral, nonparticipant spectator and outlined a program for an empirical metascience of science, an ethological approach to epistemology of science.

Naess used the idea of a dispassionate visitor from another solar system coming to study Earth-based scientists to demonstrate the possibility of completely describing both the activity of researchers and the contents of knowledge without drawing on the subjective models that governed traditional epistemology and presupposed knowing subjects or minds. The idea was to study or rather "witness" science similar to the way experimental psychologists study rats, but without falling into the trap of imposing their own experience of reality and their preexisting conceptual models of reality ("maze epistemology"), or their scientific pretensions. In the view described in *Erkenntnis*, knowledge is cognition—it is an activity with intention—and this helps to dismantle the subjectivist dualism between the content of knowledge and the activity of research. Naess's interest was in describing these patterns of research activity. He argued that the *terminology* associated with scientific activity—which is bound to the subjective-reality model—changes in leaps and bounds, not the *patterns of research activity*, which are in constant, but gradual, flux. With this argument that

change in science happens gradually, by generalization and differentiation, Naess foreshadowed his response to Kuhn well before *The Structure of Scientific Revolutions* was published in 1962.

With *Erkenntnis*, Naess also anticipated ideas that later became prominent in linguistic philosophy, such as the importance of ordinary language over formal systems and the importance of using observation of contrasts and discriminations to build up understanding of systems. In the end, presaging his own radical pluralism to come, Naess seems to relax his early position on the importance and possibility of creating a metascience of science from the “far outside” and ultimately comes to view subjective and behavioral models as two different point-of-departure formulations in an indefinite plurality of equally valid approaches for a metascience of science. This refined perspective is taken up in Naess's 1965 article “Science as behavior” (in SWAN IX), which returns to the prospects and limitations of creating a behavioral metascience to study the scientific enterprise, but this time from the “near outside.”

At age twenty-four, after receiving his Ph.D. from the University of Oslo for his work on science as behavior, Naess returned to his interest in the problem of truth. A particular concern was the inadequacy of philosophers' intuitive methods for capturing how lay people conceived and used the term *true*. In 1937 and 1938 he developed and tested an empirical approach for using questionnaires and statistical analysis to investigate non-philosophers “commonsense” views on the notion of truth. He then related these notions to philosophers' theories of truth. Naess found an amazing diversity of views among the amateurs. He also found that their views, although typically devoid of philosophical pretensions, generally covered the views represented by professional philosophers. This work elicited substantial controversy, most of which came from philosophers who viewed it as undignified to use questionnaires and statistics to investigate one of the great problems of humanity. Naess's results were published as “*Truth as Conceived by Those Who Are Not Professional Philosophers* (1938). A summary of this work is presented in Naess's “Common Sense and Truth” (in SWAN VIII). Naess's continued application and refinement of these techniques would evolve into empirical semantics.

In 1937 Naess fortified his lifelong fascination with the arctic climate Hallingskarvet by building Tvergastein, his now-famous rustic and remote hut, at its base, a three-and-a-half-hour trek from the train station at Us-

SERIES EDITOR'S INTRODUCTION

tao set. He outfitted the hut with Rube Goldberg oil lamps that also served as stoves for warming tea and with an eclectic library of teach-yourself language manuals, Sanskrit-English dictionaries, astronomical and wildlife field guides, novels by Dostoyevsky and Ibsen, letters of Spinoza, and a complete philosophy library. Following his passion for amateur science he also created “institutes” of petrology, chemistry, zoology, hydrology, and botany at Tvergastein. Naess has written the bulk of his work at Tvergastein and spent the equivalent of about twelve of his ninety-two years living there. The enormous open views at Tvergastein afforded Naess the distance and perspective he so craved while insulating him from philosophic fashion and dogma. Here he had the luxury, freedom, and good fortune to pursue his own interests free from the banalities and distractions of academic life. After completing what is now Tvergastein’s main room, Naess went on to perform postdoctoral research at Berkeley (1938–39) with the pioneer of empirical psychology, E. C. Tolman. At Berkeley, he went from studying the behavior of rats faced with many possible alternatives to studying the behavior of the scientists studying the rats.

Naess returned to Oslo in 1939 to be appointed to the University of Oslo’s Chair of Philosophy at the age of twenty-seven. On April 9, 1940, German forces invaded Norway; it would remain under Nazi rule for the next five years. This was a harrowing time for academics throughout Europe. Arne tried to maintain his unruffledness, pouring himself into research and curricular reform initiatives intended to widen and expand the perspective of university undergraduates. He tried to stay at Tvergastein often, and this afforded him some peace and solace in a world of great tension. Before long, however, even he was drawn into the resistance movement. In the fall of 1943 he played a central role in foiling a Nazi attempt to deport University of Oslo students to concentration camps for “reeducation.” The University was subsequently closed and Naess became even more committed to the resistance movement and his research. By this time he had developed great admiration for Gandhi’s catalytic 1930 *satyāgraha* campaign, the march to Dandi in protest of the British salt tax. Naess was greatly impressed with Gandhi’s idea of trying to meet one’s opponent in a manner that would calm passions and facilitate truthful communication. He thought such an approach could have had a significant effect on quenching the Nazi expansion, *if* the necessary infrastructure to support *satyāgraha* had been created in European countries. After the war,

Naess used these insights in his efforts to bring together suspected torturers and the families of torture victims to gain a sense of closure on the fate of their loved ones—and to avoid having the “traitors” subjected to equally horrid persecution. In 1948 Naess was invited to be the scientific leader of a new UNESCO project created to explore ideological controversies between the East and the West. He was soon off to Paris again, this time to pursue his interest in using philosophy to address questions of social and political importance.

The Cold War was a tinderbox and two core ideological conflicts revolved around use of the terms *democracy* and *freedom*. Naess was asked to address both but countered that UNESCO's requirement that he deliver a report within one year made it essential for him to consider *democracy* first. His goals were to clarify what people mean when they use the term *democracy* and to understand the causes of ambiguity and confusion that result from its use. After an extensive literature review, which chronicled historical usage of the term, Naess and his assistant, Stein Rokkan, prepared a thirty-question survey that was distributed to almost 600 international experts in the fields of philosophy, law, history, political science, sociology, economics, communications, and logic. Naess used the roughly 100 replies to create an empirical study of “agreements” and “disagreements.” The study demonstrated *democracy's* richness, diversity, and multiplicity of meanings and thus undermined its misuse in both the East and the West. This incited detractors from every ideology, who roundly criticized the resulting report, *Democracy in a World of Tensions*, which according to Naess “was promptly sold out and never reprinted by UNESCO due to the politically dangerous character of its items.”²³ Naess's “Analytical Survey of Agreements and Disagreements,” along with two other pieces on ideological convictions and rationality, appears in SWAN IX.

The UNESCO democracy study was the first and last international, large-scale application of Naess's empirical semantics approach. He was originally interested in doing another study on “cultural diversity,” but neither this nor the “freedom” study came to fruition. Naess learned—much to his chagrin, and as his superiors had warned—that UNESCO was a place for writing reports; it was no place for conducting research. Naess's frustration with the UNESCO experience and his wanderlust for the perspective of mountains led him to daydream first, and then to “pursue non-essentials”:²⁴

SERIES EDITOR'S INTRODUCTION

The arguments against abandoning the imaginary joys of the Himalayas for an actual expedition seemed strong to me, and so they still do. But in the autumn of 1948 the longing for the mountains pushed aside all sensible considerations. For the first time since I was twelve years old, I had to do without a summer holiday in the mountains. The safety valve guarding one against exaggerated climbing expeditions was thus removed. Added to this came the great disappointment in my own work. Lured by UNESCO's plans of philosophical research into international ideological conflicts, I had been tied up in Paris for nine months. Such large-scale extravagant schemes prove, however, impracticable. Too much nationalism and too little belief in research prevented UNESCO from getting the number of nations to subscribe to such long term schemes. By the way of compensation, I indulged at night in delightful trips to the Alps. As the situation got worse, this was, however, not sufficient compensation; the material was exhausted. Then my fantasies took me to the Caucasus. Later I had to go all the way to Persia, Afghanistan, Hindu Kush and India, and so I was committed.²⁵

Although Naess's research interests and total view continued to evolve after 1953, the general philosophical approach of the mature Naess, outlined at the beginning of this essay, was basically in place. Naess has described his philosophical work as falling into four periods or phases. From the mid-1930s until about 1940, he focused on philosophy of science. Then until about 1953, he concentrated on empirical semantics. A short period, surrounding the publication in 1968 of his major work on the zetetic scepticism of Pyrrho, ends when, at the pinnacle of his philosophical career, he sought early retirement in 1969 to devote himself more fully to ecological issues and activism. Naess has commented that this effort to be more actively engaged in social and political conflicts reflects his desire "to live rather than function." This view adequately reflects coarse, general trends, but it fails to do justice to Naess's philosophical approach, which has him mine a larger range of topics and return to them in a helical fashion throughout his life. I would rather describe his work as falling into thematic areas that were picked up, sometimes put on ice, but returned to periodically throughout his life. Although I concur that the period after his formal retirement can be seen as emphasizing ecological philosophy and activism, the two decades between 1960 and 1980 also represent a period of considerable productivity on conventional academic philosophical topics. It was in those decades that Naess produced important work, especially, on

scientific and cultural pluralism, Gandhi and Spinoza scholarship, history of philosophy and philosophy education, and normative systems theory. He has written on a wide range of important philosophical topics even into the 1990s and beyond, during which time he produced, among other works, his *Life's Philosophy* (2002; coauthored with Per Ingvar Haukeland), introductions to the philosophy of Gandhi (2000) and Spinoza (1999), and *Introduction to General Relativity and Its Mathematics* (1998; coauthored with Øyvind Grøn).²⁶ An adequate sketch of Naess's subsequent research interests and philosophical development can be gleaned from the following brief discussion of the volumes in the *Selected Works* and the discussion, at the end, of how his earlier work figures into the evolution and exegesis of deep ecology.

Naess's best-known philosophical work is likely *Interpretation and Preciseness*, published in 1953 (SWAN I). It is an attempt to convince the world of analytical philosophy about the types of approaches that are necessary, from the standpoint of a radical empiricist, to adequately interpret terms and point-of-departure statements (T_0 statements), given the manifold of plausible interpretations. It highlights the role and potential of experience in relation to intuition and reflection by requiring that every direct or implied hypothesis regarding the actual use of terms, phrases, or sentences be testable. In addition, it responds to the ostensibly antiphilosophical sentiment in *Erkenntnis* by clarifying the function of and relationship between point-of-departure statements and precizations. In Naess's semantics, the most general statements, T_0 statements (words or sentences), are phrased in ordinary language and are intended to be philosophically neutral. T_0 statements serve as points of departure for investigations of possible interpretations. When a new interpretation of an expression eliminates some of the ambiguity of a preceding interpretation, without adding any new ambiguity, it is said to be a "precization." Thus, a sentence T_1 is more precise than a sentence T_0 when every plausible interpretation of T_1 is also a plausible interpretation of T_0 but at least one plausible interpretation of T_0 is not a plausible interpretation of T_1 . This process of using successive differentiation to better understand people's interpretations of terms, phrases, or sentences can go on almost ad infinitum; it is limited only by time, resources, imagination, and willing test subjects. With this process, however, Naess has created a formal approach for classifying different statements (interpretations) based on users' "depth of intention," the point at which they no longer, explicitly or implicitly, accept or embrace higher levels of precization. A focal point is

SERIES EDITOR'S INTRODUCTION

Naess's approach of directly employing surveys to explore systematically and empirically the meanings of terms, phrases, or sentences based on their occurrences. Naess also created a formal procedure for comparing occurrences, both interpersonal and intrapersonal, that involves performing tests for different forms of synonymy. Naess has applied his empirical semantics approach to explore the meanings of "truth," "democracy," "it is the case," "certain," "perfectly certain," and "extremely probable" (see SWAN VIII for additional details on and applications of empirical semantics).

In *Scepticism* (SWAN II), published in 1968, Naess takes on the generally accepted position that scepticism, if widely embraced, leads to the intuitively false conclusion that we cannot know anything. Naess explores the variety of historical interpretations of scepticism in light of Sextus Empiricus's outline of Pyrrhonian scepticism. Three categories of philosophical positions on the question of truth are considered: Dogmatists claim at least one truth, Academicians negate the possibility of finding any truths, and Pyrrhonists neither assert that they have found any truths nor assert the impossibility of finding one. Naess takes a sympathetic view of this last group, arguing that this form of zeteticism can represent both a viable philosophical position and a way of life that supports positive mental health. What ultimately sets this position apart is not that supporters are fundamentally opposed to making acts of assertion, to stating that "something is the case," but that they do not make such assertions with the conviction of truth. Naess also uses empirical semantics to demonstrate support for this position on rational and epistemological grounds. Distinguishing between one's philosophical view and the necessity of firm, socially responsible action in everyday life, he also responds to the common notion that this radical nondogmatism generally leads to paralysis of action. In the end, Naess argues that adopting this updated view of Pyrrhonic scepticism could lead to quite the opposite, a more open-minded approach to philosophy and life. Further elaborations on particular aspects of Naess's Pyrrhonism along with a response to Rescher's reappraisal of scepticism appear in SWAN VIII.

Which World Is the Real One? (SWAN III), which was first published in 1969 and revised in 1982, is, in part, an attempt to reinvigorate appreciation and study of the broad variety of philosophical outlooks and total views that exist in Chinese, Indian, Greek, Western, comparative, and recent philosophy. It makes use of Naess's empirical semantics, developed in *Interpretation*

and Preciseness, to argue that it is an illusion to assert that combined scientific and philosophical or “purely” philosophical syntheses of such total views can exist. Naess argues that the results of science cannot be integrated into any single world picture, in part because such attempts at synthesis are necessarily fragmentary and because valid multiplicities of syntheses exist. He also takes up the question of the comparability of total views. Such comparisons, although important, are inevitably shaky because, despite admirable aspirations for standing back to obtain a meta-perspective, real people can never totally throw off their own total views; regardless of how explicit those views may be or of how conscious of them their holders are, biases are unavoidable. We always have our own perspective to contend with. For Naess the inevitable conclusion is that pluralism is inescapable and nothing to lament. He combines these points of view with a discussion of cultural anthropology to argue for the critical importance of supporting the flourishing of rich cultural diversity. Additional articles elaborating themes related to the significance of maintaining cultural diversity and its relationship to ecological sustainability appear in SWAN X.

In *The Pluralist and Possibilist Aspect of the Scientific Enterprise* (SWAN IV), published in 1972, Naess suggests that scientific theories must be understood in the wider context of the plural rationalities from which they spring. Science is not autonomous. Nor can it be seen justifiably as arising independently from the general enterprise of building philosophical systems. Furthermore, the relationship of models to reality is always indirect. This volume should be seen as an effort to erode the popular misconception of science as infallible and a viable surrogate for religion, not as an attempt to build a unified theory of science within one system, which Naess had long since rejected. Because no theory can ever be either fully verified or falsified, there exists a significant freedom of choice in both modes of exploration and theories that one can tentatively adopt. The notion of “fundamental theories” is immediately called into question. As the undemonstrated (and often undemonstrable) assumptions upon which theories rest are changed, a huge multiplicity of possibilities for future theory development arises, thus possibly helping to inspire a renewed enthusiasm in science by broadening our concept of rationality and restoring the role of imagination. Articles extending or elaborating on the ideas in *The Pluralist and Possibilist Aspect of the Scientific Enterprise* appear in SWAN IX.

Naess's third book on Gandhi, *Gandhi and Group Conflict* (SWAN V),

SERIES EDITOR'S INTRODUCTION

was published in 1974. This book develops an intellectually rigorous presentation of the theory of *satyāgraha*—the way of militant nonviolent resistance—as a strategy for conflict resolution. This work is a paradigmatic example of Naess's approach to research and writing. As the eminent Norwegian social scientist and peace researcher Johan Galtung has suggested, Naess's 1955 *Gandhi's Politiske Etikk* (Gandhi's political ethics)—with Galtung—and his 1965 *Gandhi and the Nuclear Age*, along with his articles that analyze or extend on Gandhi's work (see SWAN IX and X), act as exercises or drafts for this, his major work on Gandhi.²⁷ Using Gandhi's own recorded accounts, Naess explores the norms and hypotheses tacitly employed by Gandhi in his nonviolent campaigns and then uses these to create the first philosophical and logical systematization of Gandhi's approach to militant nonviolence. A careful investigation of Gandhi's two ultimate norms (as interpreted by Naess), "Seek complete self-realization" and "Seek truth," and his belief in *advaita* (nonduality), along with a consideration of their parallels to Spinoza's unity thesis, will reveal interesting insights into Naess own characterization and use of "Self-realization!" as the single ultimate norm of his Ecosophy T. Naess also considers Gandhi's approach to nonviolent conflict resolution in light of contemporary reactions against the use of nonviolence by Frantz Fanon, Malcolm X, Stokley Carmichael, C. V. Hamilton, and Sartre. He then examines Gandhi's ideas and intentions regarding group conflict in light of the ideas and intentions underlying other modern philosophies of conflict, including those of Luther, Nietzsche, Tolstoy, and Jaspers.

In *Freedom, Emotion, and Self-Subsistence: The Structure of a Central Part of Spinoza's Ethics* (SWAN VI), Naess uses symbolic logic to present a formalization and partial reconstruction of a small but important part of the *Ethics*. Spinoza's system is embedded in the seventeenth century and expressed in Medieval Latin. Two of Naess's goals are to bring empirical analysis to bear in trying to interpret and update Spinoza's system and to make Spinoza's insights more accessible and relevant to contemporary readers. To perform his reconstruction, Naess draws heavily on a small book he produced in 1962, *Equivalent Terms and Notions in Spinoza's Ethics*, which lists and discusses 243 equivalences that are directly asserted or suggested by Spinoza in the *Ethics*, according to Naess.²⁸ Accepting the transitivity of the equivalence relations as a general rule, Naess argues that a vast array of structural relations can be elucidated (many of these are often only suggested or implicitly asserted by

Spinoza). One of Naess's key conclusions is that every living thing is to some extent "in itself" and to some extent "in something else" due to the presumed gestalt nature of reality. Another is that the terms *substance*, *attribute*, *God*, *mode*, and *Nature* are "expendable"; Spinoza's basic nondualism is made clearer by Naess. A third conclusion is that *to be active* and *to understand* cannot be systematically distinguished in the *Ethics*. This notion, which has important implications for philosophy of science, is also embedded in Naess's conclusion in *Erkenntnis* that knowledge is cognition—the content of knowledge and the activity of research cannot be cleanly separated. Naess uses his analysis to explicate three main themes of Spinoza's system: the importance of a notion of uncoerced freedom (not coerced by externals), the importance of developing and acting on strong emotions to make progress in achieving higher levels of freedom, and the importance of joy that activates the complete person (as opposed to joy that simply activates part of the body or the soul). By clarifying the semantic structure of a central part of the *Ethics* with his own logical structure, Naess explains that there exists a wide variety of possible interpretations of the contents of the *Ethics*. Articles on Spinoza's determinism and its relationship to freedom, Spinoza and Māhāyana Buddhism, "Spinoza's Finite God," and other Spinoza-related topics appear in SWAN IX. Articles that explore Spinoza as an inspiration for deep ecology appear in SWAN X.

The English translation of *Communication and Argument: Elements of Applied Semantics* (SWAN VII), which was first published in 1966, is largely a popularization of the central ideas in *Interpretation and Preciseness*. The English edition is a somewhat watered-down version (no exercises) of the Norwegian edition that from 1941 to 1969 was used by nearly 100,000 university students in the *examen philosophicum*. Its purpose, to quote the *Times Literary Supplement*, is " . . .to teach people in a democratic society to think clearly, coherently, and above all responsibly." Naess's hope is that teachers use controversial examples from current events—the more emotional the better—to confront students with their own confusion and encourage them to strive for higher levels of depth of intention. The final chapter outlines six "Gandhian" rules of effective discussion, which emphasize avoiding six forms of "irrelevance in discussion."

The first two volumes of selected papers (SWAN VIII and IX) contain important material that is not covered by the preceding volumes, material that complements them, or material that builds on or reevaluates positions

SERIES EDITOR'S INTRODUCTION

taken earlier. Volume VIII includes sections on "Empirical Semantics and 'Truth,'" "Zeteticism," "Empiricism, Possibilism, and Pluralism," and "Metaphysics, Morals, and Gestalt Ontology." Volume IX includes sections on "Democracy, Ideology, and Rationality," "Philosophy of Science," "The Philosophy of Peace, Gandhian Ethics, and Communication," "Spinoza," and "Philosophical Development, Environment, and Education" (which includes an autobiographical article describing key influences in Naess's philosophical evolution, "How My Philosophy Seemed to Develop" and an interview, "Deep Ecology and Education"). A number of the especially significant articles have already been referred to, where relevant, in the discussion of Naess's philosophical evolution; other articles are discussed in the notes.

Today, Naess is, perhaps, best known for his "deep ecology" writings, the topic of *Deep Ecology of Wisdom* (SWAN X). This work began with a short unpublished paper written in 1965, "Nature ebbing out" (in SWAN X), and continues to this day. As the primary architect of deep ecology, Naess has more than seventy-five published articles and book chapters and more than sixty unpublished pieces on this topic. His only book-length discussion of deep ecology began with a short mimeograph, *Økologi og Filosofi* (Ecology and philosophy), published in 1971. The fifth revision and expansion of this initial work resulted in the 1976 classic, *Økologi, Samfunn og Livsstil* (Ecology, community, and lifestyle), which has been translated into Swedish, English (1989), Italian, Japanese, and Czech. This book has not been included in the *Selected Works* because it is widely available and currently in print.

Volume X is the first comprehensive collection of Naess's work on deep ecology—it includes a broad array of articles on its history, influences, theory, development, practice, and prospects. This volume shows how deep ecology represents the integration and culmination of Naess's lifelong interests in philosophy, social research, activism, science, and nature. It demonstrates how Naess, in his explication and elaboration of deep ecology, draws extensively from both his life experience and his research on empirical semantics, scientific and cultural pluralism, Pyrrhonic scepticism, Spinozistic nondualism and activeness in relation to problems, gestalt ontology, normative systems theory, total views, and Gandhi's concepts of self-realization and nonviolent communication. Volume X also shows how Naess's approach to deep ecology has unfolded over time, with substantial emendation, in part as a response to the worsening ecological crisis, in part to answer criticisms that deep ecology was turning into a cult or religion,

and in part to address the considerable confusion and controversy that arose from his use of provocative terminology and philosophical vagueness.

Ever since he coined the term *deep ecology* with his now famous paper "The shallow and the deep, long-range ecology movement: A summary," (in SWAN X) given at the 1972 Third World Future Conference in Bucharest, Naess's central concern has been to use philosophy and philosophical thinking to help humans overcome the ecological crisis and, ultimately, to restore the Earth to a state of rich and flourishing biological and cultural diversity (see volume X). A basic premise is that some ethical norms, particularly those grounded in spontaneous experience, can be tentatively accepted as objectively valid. An example for Naess would be the statement that "Every living being has an equal right to live and flourish, *in principle*." This statement in no way denies that maintaining our existence necessitates killing living beings. Another key premise is that the human potential for caring is not static or limited—it can be both extended and deepened. The ecological crisis is embedded in an ecocultural crisis. Its resolution will necessitate cooperation and collaboration among the peace, social justice, and ecology movements.

Naess does not see himself as "inventing" deep ecology. Rather, he gave a name and a philosophical framework to a minority tradition, a nascent social movement that has been with humanity since at least Buddha, Chuang Tzu, Saint Francis of Assisi, Thoreau, John Muir, and Aldo Leopold, and is epitomized by Marjory Stoneman Douglas's 1947 *Everglades: River of Grass* and subsequent crusade to save the Everglades.²⁹ This movement finally came of age in the contemporary era after Rachel Carson's *Silent Spring*. Naess's work on "deep ecology" can be subdivided into three main thematic areas.³⁰

What I refer to as Naess's deep ecology approach (deep ecology as an ecophilosophical approach) represents his contributions to deep ecology theory—it is essentially an outline of a general philosophy of life, which draws considerable inspiration from Gandhi and Spinoza. The focal points are encouraging ultimate beliefs that support our capacity to identify with all living beings and Naess's general, pluralistic, normative systems-based strategy for assisting individuals in the process of weaving their ultimate beliefs, descriptive and prescriptive premises about the world, ecological science, and philosophy into systematic conceptual structures for relating to the world—ecologically inspired *total views* or *ecosophies*.

His work characterizing and supporting deep ecology as an international, grassroots social and political movement, along with his work enter-

SERIES EDITOR'S INTRODUCTION

ing into the fray, addressing conflicts, implications, and practical applications of the theory, falls into the realm of contributions to the “deep ecology movement.” Supporters of the deep ecology movement are not united by a commitment to deep ecology as an academic ecophilosophy (which they may not be familiar with or embrace), but by their willingness to endorse the eight-point deep ecology platform, prepared by Naess and Sessions in 1984.³¹ Finally, work discussing his personal systematization of a deep ecological total view falls into the realm of “Ecosophy T.”

Naess coined the terms *deep ecology* and *shallow ecology* in 1972 to juxtapose what he regarded as two radically different approaches for problematizing (*Problematisieren*) and responding to the ecological crisis. In proposing the deep/shallow contrast, he made a technical semantic distinction directed at our level of problematizing—the extent to which we can, and do, coherently and consistently trace our views, practices, and actions back to our ultimate beliefs or bedrock assumptions. Naess starts with a premise, which he has investigated empirically, that at the level of their ultimate beliefs, people generally identify with and appreciate nature. He then uses this to argue that many regrettable environmental decisions are made in a state of “philosophical stupor,” in which narrow concerns are confused with, and then substituted for, more fundamental ones.

The “shallow,” currently more influential approach to environmentalism is identified with treating the symptoms of the ecological crisis, such as pollution and resource degradation. This reform-oriented approach is grounded in technological optimism, economic growth, and scientific management, not in ultimate premises that plumb the relationship between people and nature. It thus ultimately fails to address the philosophical, social, and political roots of the ecocultural crisis.

The “deep” approach, on the other hand, while in no way discounting the exigency of addressing pollution and resource degradation, adopts a broader, long-term, more sceptical stance. Doubtful about technological optimism, critical of limitless economic growth, and decidedly against valuing nature in purely instrumental terms, it asks if the shallow approach’s proposed solutions take into consideration the nature of reality and the complexity of the problems its adherents hope to rectify. Stressing the importance of addressing the fundamental roots and coevolving causes of the ecological crisis, deep ecology posits that along with humans’ special capacities for reason and moral consciousness come special responsibilities,

particularly in relation to the flourishing of nonhuman life and the ecocultural sustainability of the planet.

The deep ecology approach calls for expanding our sphere of concern to all living beings—charismatic or dull, gargantuan or tiny, sentient or not. It acknowledges that every living being has value in itself and views the flourishing of nature and culture as fundamentally intertwined—as part of one reality. This *wide-identification* is characterized by the perception that all life is interdependent; common goals bind all living beings to the life process. In Naess's view one can arrive at wide-identification by drawing on a broad diversity of philosophical or religious ultimate premises, with roots ranging from Christian Stewardship to the Gaia Hypothesis to Naess's own ontologically inspired "Self-realization!" In its most expansive form, wide-identification is the intuition that nature's interests and our own coincide, as with Naess's "Self-realization!"—something akin to a blending of the Hindu *ātman* with a biospherical Pareto-optimality principle. Simply stated, this principle asserts that the increased realization of any individual or species rests on advancing (or at least not hindering) the realization potential of all other individuals or species.

By juxtaposing these two, almost caricatured perspectives, Naess employs a technique of Gandhian nonviolent communication designed to confront core disagreements. The central premise is that society's potential to overcome the ecological crisis rests on guiding discussion and debate to its root causes. One of the primary root causes, Naess asserts, is the widespread disjunction between people's core beliefs and their actions. People, in general, neither comprehend how their practices and everyday lifestyle choices harm the environment, nor recognize how these consequences may be in direct conflict with their core beliefs—this is the primary weakness of the shallow approach. A crucial, underlying hypothesis of the deep approach is that teasing out the presumed inconsistencies between an individual's actions and his or her fundamental beliefs, while possibly engendering serious ancillary conflict along the way, will ultimately generate progress toward ecocultural sustainability.

Naess contends, as I have pointed out earlier, that humans act as if we have total views whether or not we make such structures explicit. Because our decisions regarding society and nature are guided by our total views, Naess maintains, we *should* attempt to articulate them. By making these structures explicit, we expand both our opportunities for fruitful debate and

SERIES EDITOR'S INTRODUCTION

interchange and our possibilities for creating policies that are consistent with our collective ultimate beliefs. This focus on praxis (responsibility and action) separates the deep ecology approach from more descriptive inquiries into environmental philosophy that focus on axiological questions, such as extending "rights" to certain nonhuman life-forms or grading intrinsic value. The ontologically inspired deep ecology approach attempts to counter the perception of fundamental people/environment and spiritual/physical cleavages. Its primary strategy for overcoming the ecological crisis is to help individuals avoid pseudo-rational thinking.

In relating this notion of persistently asking deeper questions to the ecological crisis, Naess broadens his concept of "depth." In the context of deep ecology as an ecophilosophical approach, depth refers to both the general level of problematizing we employ in seeking out the underlying, co-evolving causes of the ecocultural crisis and the extent of our willingness to consider an expansive array of social and policy responses, even if they necessitate changes that constitute a radical departure from the status quo. Rather than calling for a new environmental ethic or a radical change in fundamental values, Naess's approach to ecophilosophy centers on transforming practice and policy by challenging us to develop more thoroughly reasoned, consistent, and ecologically inspired total views. This work represents a culmination of his effort to integrate reason and emotion. He has created the foundation for a new and promising human/nature relationship that positions humans as plain citizens with special abilities and unique responsibilities and nature as mentor, measure, and partner rather than servant. The current state of global ecological unsustainability has made Naess state that he is optimistic about the twenty-second century but pessimistic about the twenty-first; humans have a long way to go.

Deep ecology has been criticized for being too critical of pragmatic efforts to address acute environmental problems. It has also been accused of being inherently fascist, antihumanist, antifeminist, and against having indigenous peoples share wilderness areas with nonhuman life-forms.³² As the articles in volume X will show, none of these criticisms are compatible with a sophisticated reading of Naess's writings on deep ecology as an ecophilosophical approach. This is not to suggest that deep ecology as an ecophilosophical approach has clear answers. In inspiring many people to reconsider their value priorities and more consistently relate them to their lifestyles and everyday actions, deep ecology opens more questions than it answers. Three

key issues for future research loom on the horizon. First, how can society motivate value priorities for ecological sustainability when individuals do not, on first principles, embrace wide-identification? Second, does taking a deep ecological perspective over a shallow ecological perspective actually result in better policy—policies that lead to long-term protection of cultural and biological diversity, using democratic, noncoercive, and ethically unobjectionable means? Third, how can deep ecology help resolve conflicts in environmental decision making when those conflicts result not from pseudorational thinking but from genuine value conflicts?

Throughout this essay, I have tried to show how Naess's life of rich and varied spontaneous experiences and internal tensions have shaped not only who he is as a person, but also who he is as a philosopher. Viewed separately, Naess's contributions to academic philosophy, social research, and ecological philosophy and activism can appear discordant, dilettantish, and incoherent. When, through careful study of his helical progression, his philosophical and personal maturation, the pattern of the whole unexpectedly reveals itself as a unity, the whole suddenly becomes much more than the simple sum of individual books and articles. With the distance of a meta-perspective, Naess's collective philosophical contributions can be seen as a mosaic—as a superordinate gestalt, in some sense, as a rich and inspiring, but inevitably fragmentary total view. Naess has breathed life back into the study of philosophy by turning its study back to life. With his cultivation of a meta-perspective, a whole, new (old) approach to philosophy and way of seeing the world emerges. This richly patterned mosaic, by encouraging us to celebrate our freedom and affirm life, can help us to reshape our relationship to each other and the Earth in new and promising ways.

Conclusion

It was only as a professor that I became aware of the difficulties of suppressing the significance of the development of feelings in human affairs while at the same time worshipping reason. Both are constantly needed.

Arne Naess, *Life's Philosophy*

The ten volumes of this series (along with a subsequent volume of conversations between Naess and myself on deep ecology and his philosophy)

SERIES EDITOR'S INTRODUCTION

make available for the first time access to the breadth and depth of Naess's philosophical thought. Efforts to judge the significance of Naess's philosophical oeuvre—assertions made in the first sentence of this essay—can now be taken up on an informed basis. When embarking on this process, it may prove beneficial to reflect on Henry Adams's insight on the fundamental limitations of communication, and especially the limits of communicating one's fragmentary total view, "No one means all he says, and yet very few say all they mean, for words are slippery and thought is viscous."³³ Spinoza ends the *Ethics* with the following remark: *Sed omnia praeclara tam difficilia, quam rara sunt* ("But all very clear things are as difficult as rare").

In *The Radical Spinoza*, Wienpahl translates the phrase more literally than usual, rendering *praeclara* as "very clear" rather than the typical "excellent."³⁴ The quest for clarity is painful and difficult as well as amaranthine. The alternative, however, is to abandon joy and freedom and thus meaning. This is the essence of Naess's distinction between being an *academic philosopher* and being a *philosopher of life*, between merely *functioning* and *living*. Drawing inspiration from Spinoza, Naess has cultivated a practice of both integrating reason and emotion *and* transforming negative emotions into positive ones. His challenge is before us and the frontier is long—the choice, however, is ours.

Editorial Approach

Naess has always written books as if they were exercises for himself, tentative formulations that chronicled his views at that very second but were always subject to change. As I indicated previously, many of the prior editions of his books were poorly edited and sparsely documented. Existing bibliographies were incomplete, and indexes (in the rare cases in which they existed) were always inadequate. Quotations were often transcribed incorrectly and ill-referenced. In addition, the breadth of his work was enormous and sometimes repetitive. Arriving at a plan for a representative *Selected Works* that would have a consistent format and design was no easy task.

All the selections for the *Selected Works* were made in close consultation with Naess. I would prepare recommendations from my master bibliography file and then, whenever we disagreed, we would discuss the pros and cons of the piece and whether it was appropriate for inclusion (this ap-

proach proved particularly helpful when we reached the *Selected Papers* volumes). We immediately made a decision to exclude works that were widely available and currently in print. Other important works, such as his dissertation, and his major work on lay people's conception of truth, his work on the semantics of democracy and ideological controversy, and his contributions to history of philosophy were more difficult to exclude, but the nature of the project as a selected works demanded such tough choices. I was encouraged by the fact that Naess often published articles that summarized or updated earlier works. In the end, I was able to reflect a significant portion of the ideas and concepts in these excluded works by including articles of that type in one of the three *Selected Papers* volumes.

The details of editing proved more complex. Much to my chagrin, I very humbly learned how much work goes into a project of this scale and complexity. We decided early on that the level of editing required to bring the prior publications up to the high standards of contemporary academic philosophical publishing would necessitate revised editions. We also decided that since we were preparing revised editions and Naess was alive and could review the work, we would make the role of the editor invisible and not include tedious footnotes chronicling all the changes, however significant they might be. The historical significance, intricacy, and sheer magnitude of *Interpretation and Preciseness* (SWAN I) warranted special consideration. For these reasons, we decided that it would be best to prepare only an edited version for this volume and not attempt a complete revision as with the other volumes. In the early stages of the project Naess and I worked together closely, intimately. In my effort to eliminate errors and to enhance readability, flow, and clarity of argument, I brought Naess question after tedious question when I first embarked on the project (particularly when I was in Norway as a Fulbright Scholar in 1996). After working through several manuscripts, Naess decided to place the remainder of the responsibility for revising and editing the manuscripts in my hands.

We have made our best effort to reconcile inconsistencies, make corrections, and chase down incomplete bibliographic references (in most cases no bibliographies existed for the original works). I regret, however, that some imperfections remain. I am also responsible for any new errors that have been introduced—their existence, unfortunately, is unavoidable. I am, however, heartened by a conversation I had with Naess midway through the project, after he had reviewed several drafts of revised manu-

SERIES EDITOR'S INTRODUCTION

scripts. He commented that at least 90 percent of my revisions resulted in improvement and that no significant misinterpretations had been introduced. Given the nature and complexity of this project, that sounded like odds I could live with.

Acknowledgments

A project of this magnitude, by its very nature, represents the labor and love of an entire community. It could never have gotten off the ground, much less been completed, without a fantastic and deeply committed team. I have been blessed by the opportunity to work with, learn from, and receive guidance and support from so many talented friends and colleagues. It's been a wild ride; I owe you all a tremendous debt of gratitude.

First, the inspiration for the *Selected Works* and the majority of its financial support are due to the foresight and generosity of "Miracle Doug," Douglas Tompkins, president of the Foundation for Deep Ecology (FDE). Thanks for your vision, Doug. Quincey Tompkins Imhoff, former executive director of the Foundation (and current vice president of the board), also deserves recognition for her tremendous support during the early years of the project, as do program directors Jerry Mander and John Davis. Special thanks also go to Sharon Donovan, the Foundation's publishing manager, who in the project's final years has guided it through a long and sometimes circuitous path to completion. The Foundation has also always had an amazingly gifted and dedicated staff. At one point or another, many of its staff had a hand in helping this project along—offering assistance at a key point, a kind word, inspiration, or simply good cheer and a smile. Thank you, Denise Wilson, Debi Barker, Esther Li, Lizzie Udwin, Julie Lindow, Miyo Sakashita, and Emily Lydgate.

I was also supported by the Fulbright Foundation with a senior research/teaching fellowship at the University of Oslo's Centre for Development and the Environment and Institute of Philosophy in 1996. Additional support came from Western Michigan University. Special thanks go to WMU's dean of the College of Arts and Sciences, Leonard Ginsberg, and to my chair, Thomas Bailey. My colleagues at Western Michigan University also deserve thanks for their tolerance and succor while I focused all my available energies on this project. I am grateful for their flexibility and generous support. Wil Emmert, one of WMU's Research and

SERIES EDITOR'S INTRODUCTION

Program officers, also deserves a great thanks for his patience and skillful assistance.

The project has been blessed with a distinguished advisory board—Robert S. Cohen, Bill Devall, Alan Drengson, Ingemund Gullvåg (deceased), Per Ingvar Haukeland, Kit-Fai Naess, Nicolas Rescher, George Sessions, Michael Soulé, Douglas Tompkins, and Jon Wetleson. All of the advisers offered significant assistance in one form or another. Bob Cohen graciously shared his expertise and offered invaluable advice, encouragement, and support throughout the project. Bill Devall gave encouragement and helped bring volume X to completion by coauthoring its preface. George Sessions offered advice on the selections for volume X, provided guidance, and carefully reviewed a draft of this introduction. His suggestions greatly improved its flow and clarity. Kit-Fai Naess's tremendous moral support and great assistance in locating obscure documents and preparing bibliographies were invaluable.

Alan Drengson's contribution as a project adviser and in the project's final year as Associate Editor deserves special mention. At a crucial time, when the project was stalled in its later stages, Alan stepped up to the plate and played a key role in helping shepherd the project to completion. In particular, he took over most of the day-to-day project-coordination responsibilities for the final year of the project. He reviewed the copyedited manuscripts for volumes I, VIII, IX, and X, oversaw preparation of the author's prefaces to each volume and the editors' prefaces to volumes VIII, IX, and X, and reviewed the final manuscript proofs. This was not an easy task. I owe Alan a great debt for his fortitude, commitment, and generosity. For his contribution to the difficult and taxing responsibility of overseeing the final preparation of volume I, he has been credited as its sole editor.

I am lucky to have been supported by two astonishingly capable, committed, and patient project assistants. Kim Zetter played a critical role in getting the project off the ground and keeping it on schedule for the first three years. Later, Barbara Pijan helped steer the project back on track and over some awkward obstacles after it had run off course. Their talent and dedication played a major role in bringing to life the books before you. Thank you, Kim and Barbara, for your stalwart devotion to the project.

The beautiful and elegant design of the series is the work of Tomatsu Yagi and his nephew Akira Yagi. Ralph Fowler played a significant role in executing the Yagis' design and by filling in any missing gaps. Ralph also

SERIES EDITOR'S INTRODUCTION

performed the typesetting for volumes II–VII. The skillful and efficient crew at BookMatters performed the remainder of the typesetting. Katherine Silver handled the Brobdingnagian task of project management on volumes I and VIII–X and the last crucial stages of the project with aplomb, attention to detail, and fortitude.

The bulk of the project's copyediting was performed by the meticulous and supertalented Anne C. Collins, Ph.D., copyeditor extraordinaire. Additional copyediting was provided by Mary Anne Stewart and Kathy Walker. Indexing was performed by the immensely competent Nancy Mulvaney of Bayside Indexing Service, Julie Shawvan, and Leonard S. Rosenbaum. Proofreading was provided by Carrie Pickett.

Ingemund Gullvåg translated *Which World Is the Real One?* Iver Ørstavik provided the translation of "Experts' views on the inherent value of nature." The original editions of Naess's texts were keyed or scanned by the able and efficient crew at AgAccess—David Katz, Karen van Eppen, Jacob Katz, Rachna Boon, and Tim Rice. Additional keying of articles for the *Selected Papers* volumes was provided by Nancy Ropecka and Jane Drengson. Barbara Pijan, d Jones, Tony Hainault, and Debbie Reid deserve thanks for their careful and thorough transcribing of more than thirty-five hours of discussions with Arne Naess. Thanks are also owed to Tim Quick for his help with bibliographic research for volumes I and VIII–X, and to Kelly McKernan for assisting Alan with photocopying and faxing. In addition, a special thanks goes to Robert P. Goldman, Sarah Kailath Professor of Sanskrit and Indian Studies at the University of California Berkeley, for generously and graciously offering assistance on contemporary Sanskrit and Hindi terms.

I am grateful to the dedicated and very patient staff at Kluwer Academic Publishing. I am sad that our original editor, the immensely talented Annie Kuipers, who first recognized the importance of this project, did not live to see it come to print. Stephanie Harmon, Annie's replacement, worked closely with me on editorial matters and on finding high-quality recycled paper, cloth, foil, and other materials that meet the strict environmental considerations of FDE. In the final five years, the able and gifted Charles Erkelens was our editor.

Additional advice and moral support were provided by colleagues, friends, and family: Aimee Carroll, Kirsten Coyne, Paul Craig, Neal Goodwin, Byron Hahn, Ladislav Hanka, Alastair Hannay, Anna Leidberg-

SERIES EDITOR'S INTRODUCTION

Miron, Danny Moses, Richard Norgaard, Max Oelschlaeger, Brian Recht, Stephanie Sarvar, Ed Saxon, Geir Michael Sommerhein, Petter Sorum, and Kristin Walstad. Thanks for your efforts to coax me out of the cave.

Special thanks go to d and Reuben for their forbearance and succor. Someday, all too soon, Reuben will recognize that the invisible “work fairies” that were constantly pulling me back to my office don’t actually exist. I can’t wait.

Most of all, thanks to Arne Naess for placing his trust in me—it’s been a gift, something like an extended trudge up to Tvergastein, but without the fresh air and perspective. Taking on this project has been somewhat like receiving Pandora’s box as a present—all sorts of ills and plagues reared their heads along the way. I often felt that I was on a never-ending climbing descent in the night. I was always wondering about rappelling off my rope into the abyss.

The SWAN has taken flight, and I have landed on firm ground—I think? In all seriousness, I learned invaluable lessons. The more I worked through Arne’s writings, the more open-minded and optimistic I became. I found myself cultivating perspective and looking at the problems and challenges before me with fresh insights. I also found myself responding with more grace and equanimity in my efforts to counteract the numbing effects of contemporary society.

It is strange and ironic, however, that in being the series editor for the *Selected Works* of the father of deep ecology I spent so much time inside, chained to a desk. But this is part of the paradox of working with Arne Naess. I am reminded of one of my favorite poems—Gary Snyder’s “Axe Handles.” The last few lines read:

Pound was an Axe,
Chen was an axe, I am an axe,
And my son a handle, soon
To be shaping again, model
And tool, craft of culture,
How we go on.

And then it makes sense.

Harold Glasser

2004

Notes

1. In writing this essay, I found myself drawing on more than twelve years of friendship with Arne Naess. A simple bibliography could not do justice to describing how this subtle and multilayered gestalt has been formed. My perception of Naess and his work has been shaped by more than thirty-five hours of transcribed conversations between us, countless other conversations, letters, scraps of paper, e-mails, and Arne's copious annotations in my own books and articles. Camping trips, bouldering, hikes, and cross-country skis have also helped inform my understanding of Arne Naess the fiercely competitive, playful, elfin trickster, who springs to life in nature. I have benefited from three extended visits to Norway, including a Senior Fulbright at the University of Oslo's Centre for Development and the Environment and Institute of Philosophy in 1996. I have also spent other stimulating periods of time with Arne in Svalbaard, England, California, and the deserts of Arizona and Nevada. Finally, and probably most important, I have been inspired and forever changed by my own reading and editing of his work. In this regard, both previously published and unpublished materials have been influential in forming my own perspective on Arne Naess the philosopher. One key published source has been Naess's "How my philosophy seemed to develop," in *Philosophers on Their Own Work*, edited by Andre Mercier and Maja Svilar (Bern: Peter Lang, 1983), pp. 209–26 (in SWAN IX). Another source for insightful material on Naess and A. J. Ayer (as well as six of their contemporaries) is a book created from debates by philosophers for Dutch National Television. See, especially, "The glass is on the table: An empiricist versus a total view," in *Reflexive Water: The Basic Concerns of Mankind*, edited by Fons Elders (London: Souvenir Press, 1974), pp. 11–68 (in SWAN VIII). Finally, additional perspective was offered by an article that discusses Norwegian philosophy from the end of the Second World War to just before 1980: Arne Naess and Jon Hellesnes, "Norway," in *Handbook of World Philosophy Since 1945*, edited by John Burr (Westport, CT: Greenwood Press, 1980), pp. 159–71.

On some of the fine points of this essay, I have benefited from extended conversations with my colleague and old friend George Sessions. I have also profited, over the years, from the significant literature that has been created to shed light on Arne's life and work. Many of the ideas and thoughts introduced in this essay—drawn from my own firsthand experiences with Arne—can also be found in these sources. In many cases, issues only touched on here are taken up in much more detail in those sources. Five key references for historical material on Naess and the evolution of his philosophical approach are identified below (two of which are videos). A wealth of additional material is available in the five festschrifts for Naess (see details in note 15 below). The

SERIES EDITOR'S INTRODUCTION

first of the festschrifts, *In Sceptical Wonder: Inquiries into the Philosophy of Arne Naess on the Occasion of His Seventieth Birthday*, edited by Ingemund Gullvåg and Jon Wetlesen (Oslo: Universitetsforlaget, 1982), contains the most thoroughgoing analyses and critiques of Naess's earlier philosophy that I am aware of, and many of the articles have insightful responses by Naess.

Books

Warwick Fox, *Toward a Transpersonal Ecology: Developing New Foundations for Environmentalism* (Boston and London: Shambhala, 1990). See, especially, chapter 4, "Arne Naess and the Meanings of Deep Ecology."

Ola A. Hegdal and Tore Strand Olsen (illustrator), *Jeg, Arne Naess: Et Tegnet Liv* (Arne Naess: A cartoon story of my life) (Oslo: Kagge Forlag, 2001). A unique and insightful look at Arne's life, based on an idea from Arne's wife, Kit-Fai.

16. Arne Naess, *Four Modern Philosophers: Carnap, Wittgenstein, Heidegger, Sartre*, translated by Alastair Hannay (Chicago: University of Chicago Press, 1968). In the 1970s, philosophy was still influenced by the events of the Second World War. Heidegger's flirtation with National Socialism and the Hitler regime, and his unusual way of expressing himself, made it difficult for him to be considered a great philosopher. Naess's book on four contemporary

SERIES EDITOR'S INTRODUCTION

philosophers was seen as unique because he interpreted in a scholarly and positive way both Heidegger and the fiercely anti-Heideggerian philosopher Rudolph Carnap, a logical empiricist. Carnap, who was forced to flee Nazi Germany, could not fathom how Naess, as an old friend, could present positive discussions of Heidegger and himself in the same book. The other two philosophers included in the book, Wittgenstein and Sartre, also held completely incompatible views of philosophy, but Naess accorded them equally high positive appreciation.

17. For example, works by Naess that are still in print, such as *Ecology, Community, and Lifestyle: Outline of an Ecosophy*, translated and edited by David Rothenberg (Cambridge: The University Press, 1989), and *Life's Philosophy* (2002; see note 2), were not included, for obvious reasons.
18. In "How my philosophy seemed to develop," p. 215, Naess mentions the particularly strong impression, the magnificent expansion of his own "life's frame of reference," made by H. G. Wells's early popularization of the history of life, *Outline of History* (New York: Macmillan, 1920).
19. For detailed discussions of Naess's assessment of logical empiricism, see Arne Naess, "How can the empirical movement be promoted today? A discussion of the empiricism of Otto Neurath and Rudolph Carnap," in *From an Empirical Point of View: The Empirical Turn in Logic*, edited by E. M. Barth, J. Vandormael, and F. Vandamme (Gent, Belgium: Communication and Cognition, 1992), pp. 107–55 (in SWAN VIII). (The original German version of Naess's article, "Wie Fördert Man Heute die Empirische Bewegung? Eine Auseinandersetzung mit dem Empirismus von Otto Neurath und Rudolph Carnap," was written during 1937–39.) For Naess's experiences attending the Schlick seminar, see Arne Naess, "Logical empiricism and the uniqueness of the Schlick seminar: A personal experience with consequences," in *Scientific Philosophy*, edited by Friedrich Stadler (Dordrecht: Kluwer Academic, 1993), pp. 11–25 (in SWAN VIII).
20. Naess, "How my philosophy seemed to develop," p. 222.

Schilpp (Chicago: Northwestern University Press, 1939), p. 597, as quoted in Wallace I. Matson, *A New History of Philosophy*, vol. 2 (San Diego: Harcourt Brace Jovanovich, 1987), p. 454.
23. Naess, "How my philosophy seemed to develop," p. 223. For more details, see Richard McKeon and Stein Rokkan, eds., *Democracy in a World of Tensions* (Chicago: University of Chicago Press, 1951). Naess, as the scientific leader of the project, was viewed as a UNESCO administrator; he was only credited as

SERIES EDITOR'S INTRODUCTION

being the author of the questionnaire itself and the summary paper, although he was intimately involved with the project at all levels.

24. Naess went on to perform a reconnaissance of Tirich Mir (25,263 feet) in the Hindu Kush in the summer of 1949. He then led the successful Norwegian first-ascent team in 1950. The expedition, which included botanical and geological assessments of the region, is chronicled by the team members in Naess et al., *Tirich Mir: The Norwegian Himalaya Expedition*, translated by Sölvi and Richard Bateson (London: Hodder and Stoughton, 1952). Naess successfully pursued a second, vastly more technical expedition to Tirich Mir in 1964. His "The south wall of Tirich Mir East," *Himalayan Journal* 26 (1965): 97–106, discusses this expedition and includes interesting commentary on expedition philosophy and climbing ethics. The article appears in SWAN X, along with other papers on Naess's relationship to mountains and views on mountaineering.
25. Arne Naess, "Reconnaissance, 1949," in *Tirich Mir*, p. 22.

ogy approach to ecophilosophy,” the “deep ecology movement,” and Naess’s “Ecosophy T” (a particular deep ecological total view), see Harold Glasser, “Deep ecology,” in *International Encyclopedia of Social and Behavioral Sciences*, edited by Neil J. Smelser and Paul B. Bates (Oxford: Pergamon, 2001), pp. 4041–45. For a detailed discussion of deep ecology as an ecophilosophical approach with special attention to its policy implications and a discussion of deep ecology’s relationship to Naess’s earlier philosophical work, see Harold Glasser, “Naess’s deep ecology approach and environmental policy,” *Inquiry* 39 (1996): 157–87 (reprinted in Witoszek and Brennan’s *Philosophical Dialogues*).

31. For anthologies on the deep ecology movement, which include articles by Naess and other deep ecology supporters, see George Sessions, ed., *Deep Ecology for the Twenty-First Century* (Boston: Shambhala, 1995), and Alan Drengson and Yuichi Inoue, eds., *The Deep Ecology Movement: An Introductory Anthology* (Berkeley, CA: North Atlantic Books, 1995).
32. Naess rarely responds directly and definitively to these criticisms—this is not his nature. Siri Naess, however, made an interesting effort to explore the potential of using Naess’s Ecosophy T as an inspiration for a feminist normative system in her “Self-realization,” in *In Sceptical Wonder*, pp. 270–81. She concluded that while Ecosophy T and her System F have much in common, Ecosophy T goes further by extending to all living beings its concern for activeness and creativity in relation to problems, egalitarianism, and support of the suppressed and exploited.

Author's Introduction to the Series

At ninety-two it is a great honor to be still alive and to witness the publication of my selected works in English. Few philosophers have their work published in a series, fewer still receive this honor before they die. When I was originally approached with the idea of publishing my complete works, I was overwhelmed and overjoyed, but added that not all my books and articles were important enough to merit such an honor. Selected works? Yes, and I am extremely grateful for this initiative and the final result, which presents a representative selection of my work from the earliest to the most recent. [*The Selected Works of Arne Naess* are hereafter referred to as SWAN.]

My interest in philosophy began with Spinoza's *Ethics*, which as a seventeen-year-old I was fortunate to read in Latin. I appreciated Spinoza's grand vision and trusted him implicitly as a person. I accepted that human beings could, and should, have a general outlook with the grandeur of Spinoza's, but I recognized that our individual views on this grand scale will not be identical. Through the years I have realized that there is a splendid variety of interpretations of Spinoza (SWAN VI and IX). His texts are exceptionally rich. As the years have gone on, I have focused on how he leads us to realize we can increase our freedom and sense of connection with the world through strengthening and intensifying our *positive* emotions. For example, loving and caring for our place and others leads to an expansive sense of being part of a much larger world. Emphasizing hatred and anger, on the other hand, makes us feel smaller and isolated from the world. Spinoza, as I interpret him, would express this by saying that "We are as large as our love." Increasing our freedom as human beings leads us toward life in communities colored by friendship, sharing joy and sorrow.

Before I left gymnasium [the end of secondary education] the headmaster asked me, "What do you intend to be?" My immediate answer was "A philosopher." In fact, I had already conceived of myself as one. I viewed the

AUTHOR'S INTRODUCTION TO THE SERIES

writings of many contemporary philosophers that I was familiar with, however, as vague and airy and certainly not as inspiring as Spinoza.

My doctoral thesis in philosophy of science was an effort to remind us that in science the content of a theory is not independent of research behavior—the activities of observing, confirming, disconfirming, and so on, and that these are set within a deep context of place, history, and culture. Later, as a postdoctoral researcher at the University of California at Berkeley, I studied the behavior of experimental psychologists doing animal research.

In 1934 and 1935 I studied in Vienna and while there became a member of the famous Schlick seminar, the main discussion group of the Vienna Circle. Their quest for clarity and cordial cooperation in pursuit of knowledge led me to appreciate that “What do I mean?” is an open question. I concluded that we never intend to express anything extremely definite, even in mathematics or symbolic logic. I saw the importance of using empirical methods to find out how we actually use certain expressions and sentences. I developed and applied a wide variety of such methods, which became part of the core for the empirical semantics that runs through my work. I continued to do this type of research into the 1990s, my last project being one in which I questioned experts and policy makers about their ideas of values intrinsic to the natural world (in SWAN X).

In one of my earlier studies, I reviewed about 700 articles from philosophers concerning their use of the word *truth*. For the most part, I found these unconvincing and soon started on empirical studies of the use of *truth* among ordinary nonprofessional people and schoolchildren (in SWAN VIII). Many philosophers seemed to assume that ordinary people hold very naive views about these deep matters. I found through research that, on the contrary, the views articulated by these “ordinary” people were every bit as sophisticated as those held by professional philosophers. This reinforced my conviction that, generally, we greatly underestimate ourselves. Much academic philosophy was narrowly focused and abstract. Philosophers who elicited interest in wide-ranging issues of practical and global importance, such as nonviolence and social justice, have in my lifetime said things that were considered creative, but often too far out. In spite of consistent proclamations that science neither would nor could take over all the problems discussed by philosophers, I tried to argue in ways that reminded readers of science done as open inquiry, and I tried to emphasize that it is occasionally

AUTHOR'S INTRODUCTION TO THE SERIES

necessary to perform empirical research to illuminate or support a philosophical viewpoint.

My empirical and historical research led me to realize that there are no certainties and that there is a great diversity in our spontaneous experience as well as endless ways to describe and appreciate the complexities and values of the world. Thus, I realized that I am one of those lifetime seekers that the ancient Greeks called a *zetetic* (see SWAN II and VIII). From my research on scepticism and the foundations of science and logic, it became clear to me that pluralism (every event has many descriptions and possible outcomes), possibilism (anything can happen), and a healthy scepticism (always seeking the truth but never claiming it) make up the most consistent approach to respecting the perspectives and experiences of others, human and nonhuman.

From my empirical studies of semantics, and from my knowledge of several languages, I came to appreciate the complexity of communication. Being committed to Gandhian nonviolent communication, I saw the importance of avoiding dogmatism and fanaticism. One of the most important discoveries coming from this research, leading to the publication of my major book, *Interpretation and Preciseness* (SWAN I), was the insight that we cannot avoid values in any field of endeavor or research. There are no value-free inquiries or theories. Even if we refuse to express our values, this is itself an expression and choice of values. We must, therefore, be clear about our value choices and try to make them explicit. The choices we make, as Spinoza pointed out, shape the quality of our lives, and values emphasizing positive emotions or feelings are expansive and lead to our growth. We must become ever more aware of our choices and the values involved. Even pure logic assumes certain norms. Empirical research can shed light on these matters. My colleagues in philosophy often found my empirical work perplexing. I, in turn, grew to underrate the necessity of visiting great centers of philosophy, as I preferred to be close to or in the mountains.

When I visited the United States, it was mostly to climb in the mountains or walk and camp in the desert. On one fortunate visit, I dropped in at the graduate students' discussion room at Harvard. Speaking with students who were writing their doctoral theses in philosophy, I understood that my knowledge of contemporary philosophy, and of recent important contributions in its various fields, was narrowly limited to special themes of lively personal interest. Even in later years, the tendency to take personal inclina-

AUTHOR'S INTRODUCTION TO THE SERIES

tion very seriously colored my contribution to the philosophical literature. As can be seen, though, from the titles in these *Selected Works*, my strongly felt interests span a rich variety of fields, philosophical traditions, and movements.

Since childhood I have experienced an intense joy in being together with animals and plants and in contemplating the immense evolutionary development of life on earth over millions of years. From an early age I also developed an intense love for mountains and for being in them. Much of my creative philosophical work was done at Tvergastein, my mountain hut in Norway (see SWAN X). My devotion to outdoor life is in the Norwegian tradition called *friluftsliv* (literally, free-air-life). In many respects, I approached philosophical and cross-cultural studies as if I were a field ecologist or naturalist. It was against this background that my work from the 1960s onward focused with close attention on cultural diversity, biodiversity, sustainability, and the deep ecology movement.

My work since the Second World War has been increasingly within movements such as those furthering social justice, peace, and ecological responsibility. During the war, I engaged in anti-Nazi activism, and from that time also in promilitant Gandhianism, a nonviolence that is not pacifist in the usual sense but insists that if it is a bloody fight for justice against injustice, we seek "the center of the conflict" and, if necessary, cooperate with people who use arms. During the Cold War, I participated in the "third side," against both communism and extreme anticommunism, for example, as the scientific leader of a UNESCO project bringing Marxist and anti-Marxist politicians and political science researchers together in an unbiased discussion of the essence of democracy and freedom. Some of the relevant publications are included in SWAN IX.

The broad spectrum of books and articles included in the *Selected Works* represents, in many ways, a chronicle of my passions and influences. The *Selected Works* record, albeit in an inevitably fragmentary way, one possible expression of these. My dream and hope is that some readers will be inspired by their sheer variety, and that young philosophers will be encouraged to let strong personal motivations steer their studies.

Working habits vary. Some people write an article and go on to the next without looking back on the old one; others come back from time to time, radically revising and changing the old one. The latter is my way of working. Lecturing in many places about these subjects, I have found it

AUTHOR'S INTRODUCTION TO THE SERIES

natural to revise the old manuscripts until sometimes very little is left of the original. Therefore, I have always viewed my writing as preliminary; a year, five years, ten years after publication of the first editions I have itched to revise, *thoroughly* revise them. When my first book was printed in 1936, I went to watch the hulking presses printing out one page at a time. I was terrified, thinking of mistakes or some awkward sentences being duplicated again and again.

When I was offered the opportunity to have a selected-works series published, I immediately thought I would like to review all my work and ask how, from today's perspective, I might answer the difficult questions I had earlier attempted to probe. Such a task would have been a particularly difficult proposition, because although many of my books and articles contain new ideas, the ideas are often not developed as well as I might have hoped. But alas, I am saved—at my age there is not time for me to accomplish such a comprehensive reevaluation of my work; I do not even have the capacity to do it now in any case.

Who could contemplate undertaking a publishing project of such ambitious proportions? Douglas Tompkins, mountaineer, entrepreneur, protector of wilderness in Chile and Argentina, and creator of the Foundation for Deep Ecology, is such a person. "Miracle Doug," as I call him, likes the idea that the deep ecology slogans and the deep ecology approach were introduced by a philosopher. I am grateful to him for his firm conviction, inspiration, and great generosity. My gratitude, however, extends well beyond my thanks to Doug, to others who have supported and championed this project.

Quincey Imhoff, when executive director of the Foundation for Deep Ecology, supported SWAN with generous grants and other contributions. SWAN has also benefited from faithful assistance and cooperation in the preparation and editing of the manuscripts. The late Professor Ingemund Gullvåg prepared the initial translation of *Which World Is the Real One?* (SWAN III). Professor Alastair Hannay translated the first edition of *Communication and Argument* (SWAN VII) and offered invaluable suggestions for improving the readability of the first editions of *Scepticism* (SWAN II), *The Pluralist and Possibilist Aspect of the Scientific Enterprise* (SWAN IV), and *Gandhi and Group Conflict* (SWAN V).

Most of all, however, I am grateful to Harold Glasser, the series editor, and his assistant, Kim Zetter, who oversaw all aspects of the project from design to production. Glasser's unique combination of intellectual tenacity,

AUTHOR'S INTRODUCTION TO THE SERIES

attention to detail, mastery of my work, and cooperative spirit made him a natural to take on the monumental task of selecting and editing my works. Glasser not only labored to improve the English and clarity of each manuscript, but his keen ability to ferret out countless technical and pedagogical errors has resulted in substantial new editions of volumes II–VII that are both far more comprehensible and accessible than the originals. I thank him for his valiant work on this project, both during his stay in Norway as a visiting Fulbright professor, where we collaborated on a strategy for revising the previously existing material, and in the subsequent years it has taken to complete the project.

From the beginning of the SWAN Project in 1994, Alan Drengson has encouraged and helped to move this work forward in numerous ways. Especially in the last crucial stages of completing volumes I, VIII, IX, and X, his help and editorial oversight have been invaluable. Thanks for his devotion, good humor, and positive enthusiasm. Thanks to both Drengson and Tim Quick for their extensive bibliographic research. Thanks to Bill Devall for his support and encouragement and especially his help on the completion of volume X, *Deep Ecology of Wisdom*. Thanks to Anne Collins for her outstanding work as the copyeditor of the SWAN volumes. Thanks to George Sessions for his support and encouragement.

Last, but certainly not least, immeasurable thanks go to my wife, Kit-Fai Naess, who has worked beside me throughout the years to provide invaluable assistance, encouragement, and inspiration.

Arne Naess

2004

Author's Preface to This Edition

We sometimes say “She has an open mind” or “His mind is closed.” Doors or windows may be more or less open or closed, and they may be completely open or shut. What would correspond to this when we speak of being open to the possibility that an assertion is not true? What about full openness to this possibility, whatever the assertion imagined so far? Would one’s capacity to make a decision completely disappear? Is it deadly to have a completely open mind as to truth and falsity?

In relation to knowledge and truth Sextus Empiricus divides philosophers into three categories: (1) those who believe they have found at least one truth, (2) those who deny the possibility of establishing any truth, and (3) those who neither think they have found a truth nor believe it is impossible to establish any; they have not given up on finding one, a search they tentatively suppose is not of great importance to their happiness. It is not deadly at all. Sextus called them sceptics, Pyrrhonic sceptics, or just seekers (*zetetics*).

I find it strange that the term *scepticism* has been used mostly to refer to those who dogmatically reject the possibility of knowledge in the sense of establishing truths. Philosophers have published a series of good arguments against this view. Very few take up the third view for serious discussion. It is an approach with a kind of complete openness in principle. Because I feel that wonder is not only the beginning but also the likely end of any philosophical inquiry, the third approach has always been of central interest to me. In this SWAN II volume, I show why I feel at home with the kind of openness favored by Sextus. One who has this kind of openness and seeks I call a zetetic. (SWAN VIII contains papers on zeteticism.)

To me every clearly stated question, if taken seriously, leads to other questions, and sooner or later we arrive in the realm of philosophy. From there I see no *theoretical* escape. In practice, of course, I get tired and certain

AUTHOR'S PREFACE TO THIS EDITION

tentative solutions remain on my list. Philosophy starts and ends for me with wonder—or does it? I have not yet thought my last thought—or perhaps I have?

To wonder is not the same as to be in a state of doubt. Pyrrhonic sceptics and zetetics tend not to doubt but to trust. A zetetic is always learning and changing and has a flexible attitude toward language and life.

Arne Naess

2004

Author's Foreword to the First Edition

In the present work I attempt to give a concise account of sceptical philosophy in its most radical and important form and try to remedy certain weaknesses in the traditional ways of describing this philosophy as well as respond to certain arguments that have been brought against it.

I believe there are many good reasons for investigating various forms of thinking traditionally referred to as scepticism. First, as with many other viewpoints, the force of sceptical attitudes makes itself felt acutely, making one at least temporarily a sceptic. Second, when we feel far from scepticism, it is often because we have accepted or postulated certain fundamental positions or principles, but only for the time being. From time to time these fundamentals appear arbitrary or at least less evident, obvious, or even useful, and then the attitude of sceptical “looking around” reasserts itself. Thus, many of us are nomads in philosophy, and sceptical attitudes or doctrines are our recurring pastures. Third, sceptical philosophies, and especially Pyrrhonism as pictured by Sextus Empiricus, are mostly misunderstood and apt to be described in ways that make them appear unnecessarily crude or absurd. There is room for a more sympathetic study of the ancient texts. The reader will find that my references to contemporary philosophers who discuss scepticism are mostly critical. This must not be taken to imply a general disagreement with them, let alone a negative assessment of their contributions. It is simply that discursive economy requires that I concentrate on those points on which I disagree, or agree only with qualifications. I should like to say that I find many contemporary discussions admirably clear and pertinent, perhaps especially those that I find reason to dispute on certain points.

I am grateful to the Norwegian Research Council for Science and the Humanities for a grant making it possible to carry through the historical research needed in this project, and to Mr. Alastair Hannay for valuable assistance in revising the manuscript.

I

Pyrrho's Scepticism According to Sextus Empiricus

Introduction

In this chapter I offer an account of only one special form of scepticism, the philosophical activity and view known as Pyrrhonism. Moreover, the account I give is of Pyrrhonism as represented by Sextus Empiricus in his work *Outlines of Pyrrhonism* (1933). Thus, my treatment of scepticism might seem to be doubly narrow. However, there are some reasons for not attempting a more inclusive picture. One is that such presentations can already be found in textbooks on Greek philosophy, in philosophical and other reference books, and in a number of monographs devoted solely to scepticism. But there is a more compelling reason as well.

Apart from a few monographs from between about 1860 to 1920, there are no accounts of Greek scepticism that seriously undertake the task of seeing the sceptics as they saw themselves. It is, of course, a very common experience that if one studies a philosophy closely, one becomes dissatisfied with existing accounts of it. This case, however, is a special one: the distance between what Sextus Empiricus seems to convey to his reader and the usual account we are given of what he says is altogether too great to let go unnoticed.

There is also a special reason for concentrating on Sextus's account of Pyrrhonism. As he portrays it, Pyrrho's scepticism is, so far as I can judge, superior to any other variant in its consistency, its radicalness, and also in its *practical* importance for intellectually gifted persons with high ideals of sincerity and honesty. Thus, Sextus's Pyrrhonism provides us with a yardstick and a fundamental framework by means of which all forms of less radical, less consistent scepticism may be measured and mapped out. I therefore invite the reader to try to understand this radical scepticism and to be patient with what at first sight can hardly fail to seem absurd or far-fetched.

This, then, is the motivation for our short and general account of but one of the varieties of scepticism: Pyrrhonism as depicted by Sextus Empiricus. The sources, as with all philosophical classics, lend themselves to different interpretations, and I do not wish to try to convince the reader that my own interpretation is the only one that can be constructed on a historical basis. But I think that many will agree that the interpretation I give presents the sceptic (here in the sense of the Pyrrhonist as pictured by Sextus) as less inconsistent or preposterous in his claims than he is made to appear in some of the most widely read accounts.

A Short Account of Sextus's Pyrrhonism

Much learned historical work has been undertaken to find out which sceptics taught what. I shall try neither to add to nor subtract from the conclusions of historians of philosophy on this point. The decisive thing to note is that the only extant work by a Greek sceptic is that of Sextus Empiricus. The study of Greek scepticism must therefore in the main be a study of his texts.

There are, it is true, reasons to suspect that Sextus is not altogether accurate in what he says about other sceptics and that Pyrrho in particular might not have approved of all of Sextus's references to him. But I shall not be concerned with this question; instead I shall try to give a summary account of Pyrrhonism as depicted by Sextus in *Outlines*. What marginal notes and exclamations Pyrrho himself would have put into a copy of Sextus's *Outlines* is an intriguing topic for speculation. The account I shall give is something that can be assessed and tested by studying the actual texts of Sextus. In what follows, the terms *Pyrrhonism* and *scepticism* will be used as shorthand for "Pyrrhonism as pictured by Sextus." Of course, Sextus does not assert the truth of any of his sentences about Pyrrho as a historical person.

But first, in order to clear up some ambiguities, a few remarks on the use of the term *scepticism*. The term is used in many ways, which can be distinguished by separating four dimensions of variation:

1. *Comprehensiveness*. *Scepticism* is often used as short for "religious scepticism," for "ethical scepticism," or for some other nontotal field of human concern. The most comprehensive kind of *philosophical* scepticism covers all fields of articulated cognition or discursive thinking. Pyrrhonism belongs to that kind.

2. *Intensity*. If a philosopher thinks we are able at least sometimes to distinguish the more probable from the less, but not the true from the probable, or the false from the improbable, he is often called sceptical. But another philosopher is also sometimes said to be sceptical who suggests that the more probable can never be distinguished from the less. The difference may be said to be one of intensity.
3. *Self-reference*. If a thinker states that nothing can be known, the question arises whether he thinks he can know that he cannot know anything. That is, there is an exception: we can know that it is impossible to reach knowledge. If he answers no, we may say the statement is intended to include itself in its reference. Sometimes the former position is called Academic or Dogmatic and distinguished from the latter, the Pyrrhonic. This is the terminology I shall adopt. (It may of course be disputed whether this third dimension, of self-reference, is independent of the first and second. It is, in any case, convenient to treat the question of self-reference as a unique one.)
4. *Articulateness*. As a professional philosopher, the sceptic must articulate his scepticism, preferably in words. The great sceptics of the classical Greek tradition were not only masters of sceptical verbal articulation but also sceptical in their nonverbal attitudes. In the history of ideas and in general cultural history, nonverbal attitudes also count. A person may be termed a sceptic even if he does not express his bent of mind verbally.

For our own introductory purpose, the best way of identifying sceptics is to follow Sextus in his narrative of how (certain) gifted persons develop by stages into mature sceptics. Seven points characterize their development:

1. Faced with “contradictions” in things and with philosophers who contradict one another, gifted people become frustrated and undecided and set out to discover for themselves what is true and what is false. They are led to consider all kinds of doctrines and arguments in the hope of restoring their peace of mind.¹
2. Those who investigate matters systematically eventually become philosophers. As such, they fall into one of the following three main classes: those who claim that they have found at least one truth, those who claim that truth *cannot* be found in any matter, and those who

neither claim that they have found at least one truth nor claim to *know* that truth cannot be found, but persist in their seeking (*Outlines*, bk. 1: 1–3).

These three groups are called respectively Dogmatists, Academicians, and Pyrrhonic Sceptics. (The first two are also called dogmatic in a wider sense.) It is important to note here that in contemporary Anglo-American professional philosophy, the sceptic is identified with the person who positively denies that one may know anything for certain. That is, the sceptic is identified with what Sextus calls the Academician. The Academician is an active participant in philosophical discussion, maintaining a definite position, a standpoint; the sceptic, in the sense of Sextus, has no position, as we shall see. Although he throws arguments into the discussion, he takes no part in the evaluation of truth-value. Although he confronts the dogmatist with counterarguments, he does so without accepting any of them as true or valid.

3. The personal development of the sceptic is of a peculiar kind: he finds that to any pro-argument for a doctrine or proposition there can be found an at least equally strong contra-argument, or that, summing up pros and cons, the arguments balance one another. Or, to be more accurate, the sceptic finds no better grounds for accepting the arguments in *favor* of the doctrine than for accepting those *against* it (*Outlines*, bk. 1: 8, 10, 12, 26). These statements require careful interpretation.

It would be a mistake, for example, to attribute to the Pyrrhonist a *principle*—a general rule—of opposing all arguments with equally strong arguments. One can hold such a principle only if one is sure, or can take it for granted, that there are always such arguments to be found. But, as will become clear later, whether this is the case is a question the Pyrrhonist leaves open—otherwise he would tend to side with the Academicians.²

Thus, the developing sceptic (or the sceptic *in statu nascendi*) has no prejudice in favor of counterarguments. He does not look more intently for contra- than for pro-arguments. It just so happens that he finds that arguments balance one another. Or, to be more exact, it so happens that he does not find a sufficient weight either *pro* or *con-*

tra to justify a decision about what is true, or even about what is more probable. In order to stress his lack of conclusion, he prudently uses the past tense: he has not, up to now, found anything that decisively disturbs the balance between pro and contra, that disturbs his general *isosthenia*, or state of mental suspense (*Outlines*, bk. 1: 190, 200).

4. The corresponding psychological phase in the making of a mature sceptic is the gradual development of a deeply entrenched bent of mind, a state of suspension of judgment, or *epoché*. The mature sceptic decides neither for the positive nor for the negative in relation to any doctrine but allows both possibilities to stand open. The state of suspension is a form of mental rest—quietude, repose, immobility, stability (*stasis dianoías*). The suspension slowly develops into a firmly based bent of mind (*Outlines*, bk. 1: 8, 10, 196, 205).
5. To his surprise, the sceptic eventually finds that *epoché* leads to, or is accompanied by, that same peace of mind (*ataraxia*) that he set out to achieve by finding truth (*Outlines*, bk. 1: 8, 10, 12, 17, 28–30). But the mature sceptic will not, of course, claim that there is a necessary connection between *epoché* and *ataraxia*.
6. The mature sceptic obeys or follows the ordinary or normal rules of his community. He is guided, but not determined, by nature, traditions, laws, and customs. He may instruct himself in some skill or other and adopt one of them, perhaps medicine, professionally (*Outlines*, bk. 1: 17, 22–50, 226–27, 230–31, 237–38).
7. The mature sceptic is still a seeker. He does not claim to *know* that truth cannot be found in any matter. Thus, he is prepared to investigate and evaluate any new argument in relation to any conclusion. He leaves all questions open, but without leaving the question. He has, however, given up his original, ultimate aim of gaining peace of mind by finding truth, because, as it so happened, he came by peace of mind in another way.

To sum up, then, scepticism as outlined by Sextus is neither a doctrine nor a system of rules of life positively claimed to bring peace of mind. The mature sceptic is a philosopher who, like the early Socrates and some influential philosophers of our own time, makes no philosophical assertions.

The most concise exposition of the philosophy of the mature sceptic is to give an account or narrative of his life in the way Sextus does. However, since Sextus the metasceptic is the same person as Sextus the sceptic, he explicitly denies that he claims the (objective) truth of any of the statements of the narrative. Not that the sceptic cannot allow himself to *say* anything or must inhibit any tendency to do so. If he feels like it, he may express what is on his mind, and sometimes this will result in long narratives: his ways of verbal announcement are many, but they do not include assertions of truth.

Having attained peace of mind (*ataraxia*) by suspending judgment (*epoché*), and having reached general suspension of judgment by *isosthenia*, the sceptic is inclined to try to preserve *isosthenia*, that is, to look for counterarguments and counter-counterarguments. A natural expectation will build up that he will in this way retain his general suspension of mind, and he will be inclined to try to help others who are not yet, but seem to be on the way to becoming, mature sceptics.

In certain kinds of situations, those individuals following the sceptical way adopt a set of maxims or sayings—often called sceptical—such as “Arguments and counterarguments balance each other.” But here the claim ordinarily intended when someone asserts something is not made; rather, such maxims are to be taken as symptomatic of the state of the sceptical mind. Thus the maxim “No statement is true” is, according to Sextus, self-defeating as an assertion: if it is true, then it is false. The sceptic, therefore, does not feel inclined to *assert* that knowledge cannot be reached, or to venture any of the other sayings frequently taken to be expressions of a doctrine of scepticism. Although the sceptic articulates his philosophy in a most careful way, there is one manner of using language that he most carefully avoids: the assertion.

In what follows, we shall adopt the above seven-point definition of scepticism. Thus, it will be a matter of definition that the mature sceptic has peace of mind. Indeed, all traits mentioned in the seven points will belong to the sceptic by definition.³ What can fruitfully be discussed, therefore, is, among other things, the conditions and likelihood of the seven-point development and the stability of scepticism as a bent of mind and way of life. This, as we shall see later, is the same as to discuss the possibility of a radical scepticism.

The Sceptical Ways of Announcement

Sextus, then, is not a philosopher with doctrines. He will not admit to having any definite opinion as to the truth or falsity of a proposition. But in this case, how are his utterances (*fonai*) to be interpreted? What uses of language do they represent? What ways does he have of *announcing* his bent of mind?

Sextus makes use of a great variety of terms to contrast his own ways of announcing with those of the dogmatists. I shall first mention some of those used in the opening chapters of *Outlines of Pyrrhonism*.

1. *To report as a chronicler*. At the end of the first chapter, Sextus says that in what follows he does not affirm the truth of what he says, but only *reports as a chronicler* how things appear to him at the moment of writing. The crucial expression here is *historikós apangellomen*.⁴

Even someone who is, in the usual sense of the word, merely a reporter of what appears to him at the moment to be the case would claim truth for his account of the *appearances*. He would affirm that this and not something else is how it *really* “strikes him” at the moment. Later we shall see how Sextus meets this complication. In fact, he virtually retracts the view that the sceptic uses language in the same way as a chronicler or reporter. In other words, the first special characterization of the sceptical way of announcement is not a very happy one.

2. *To utter*. In chapter 2, Sextus declares that later on in the book he will give an account of how or in what sense the sceptic adopts what he, the sceptic, “shows forth” or “displays in words.” These somewhat peculiar expressions I use only provisionally. In fact, the term Sextus adopts is one that he often uses in connection with statements of doctrine—*apofasis*. One important complex expression is *skeptikai apofaseis*. Robert G. Bury translates this as “sceptic formulae,” Eugen Pappenheim as “*skeptische Aussagen*.” However, when Sextus comes to the passages in question, he does not use the dangerous word *apofasis*; instead he consistently uses *foné* (utterance). This term appears in logical and other Stoic texts in contradistinction to *lekton* (that which is, or might be, signified by the utterance);⁵ its most elementary meaning is “sound,” and by using this term, Sextus avoids

contamination with doctrinal ways of announcement. He leaves it open as to what use of language is realized: *foné* is a highly noncommittal word.

3. *To acquiesce in and accept (in words) what appears.* The sceptic does not oppose what appears to him, but acquiesces (*eudokeo*) in it. The term *eudokeo* contains *dokeo* (I opine), but apart from meaning "think well of," it can also mean "accept," or "say yes to," in a noncognitive way. He accepts (*synkatatithémi*—assent to) what, involuntarily or by necessity, appears to him (*Outlines*, bk. 1: 13). Thus, when feeling hot or cold, he will not say that it does *not* seem hot or cold to him.

From these formulations one can gather that Sextus looks on some or all of the sceptic's utterances as more or less *caused* by states of perception⁶ that are forced on him. When saying "I feel cold," the sceptic does not make an assertion *about* something; rather, he assents *to* something. Although what he says can be construed as an assertion, it is not an assertion in the sense that he positively takes a stand for rather than against something. He is not asserting *rather than* denying; nor does he *oppose* an impulse toward not saying it. He will neither affirm nor deny "It now seems hot (cold) to me" as a proposition.

4. *The sceptical formulas or phrases.* Sextus divides what the sceptic talks about into two classes, the evident (*délon*) and the nonevident (*adélon*). The "immediate" and the "mediate" may be better translations. What is said in number 3 above (*Outlines*, bk. 1: 13) holds for the evident ("I feel cold," etc.). But the sceptic also utters his famous "sceptical phrases." These make up either a subclass or a total class of his own sayings about nonevident things, such as arguments.

That the sceptic does not intend to assert something or state that something is the case when uttering his sceptical phrases, is clearly, explicitly, and repeatedly stated by Sextus himself. It would be of no avail to assert them, says Sextus, because each one "cancels itself," "strikes itself out" (*perigrafo*). Thus, even "Not more this than that," which is said when comparing the force of argument with that of counterargument, is meant to apply universally; it, too, cancels itself out, just like the (nonsceptical) phrase "Nothing is true." The same applies to "I do not decide (determine the truth-value of) anything." According to this, I do not even decide that I decide nothing.

Incidentally, neither “Nothing is true” nor “All is false” mentioned here (*Outlines*, bk. 1: 14), is included among the sceptical phrases.

5. *To put forward*. Of the sceptical formulas, Sextus says that they are *put forward* (*profero*).⁷ They are put before the dogmatist and used for didactic purposes among sceptics during their training, not to teach sceptical theorems (they do not exist), but to suggest the state of mind of the sceptic when approached by dogmatists. Their function would resemble that of certain standard exclamations such as “Well, I never!,” “Take your time!,” and “Be careful!”
6. Sextus uses such words as *perhaps*, *presumably*, and *it seems* out of standard context. That is, where he puts them they would be badly placed if they were not used to remind the reader that “this is not to be taken as an assertion.” The book’s opening sentence has an unnatural “it seems”: “Those who seek, it seems, either find what they are looking for, or reject the (possibility of) finding it, and deny that it can be grasped, or go on searching.” Most likely this is meant to be an exhaustive classification: at least Sextus suggests nothing that could be argued against it. The “it seems” serves to indicate that the main sentence is intended to function not as an assertion of a true proposition but as an utterance of some other kind. On the other hand, Sextus intends that the dogmatist should be able to evaluate the proposition that the sentence *can* be intended to express, even though it did not happen to be thus intended by the sceptic.
7. *To say something indicative of our state of mind* (how we feel about things) (*Outlines*, bk. 1: 197). Sextus says about one of the sceptical phrases, namely “I determine nothing,” that it is not meant as an affirmation; rather it is a sound (*foné*—utterance) indicative of the sceptic’s state (of mind).⁸ There are two interpretations of *indicative* that can be applied in this context: “deliberately intended to be indicative” and “indicative as a matter of fact.” The latter, perhaps, fits in best with the general attitude of the sceptic.
8. *Talking loosely*. One may talk without presupposing any definite conceptual frame of reference, taking “conceptual” here in a rather narrow sense—not in the broad way in which children conceptualize as soon as they learn to use everyday abstract terms, but as explicit definitions or closed systems of propositions. We may think of

a conceptual framework or frame of reference, therefore, as a system of definitions providing clear-cut rules of interpretation, at least for certain basic terms. Obvious examples of such terms would be *true*, *truth*, *fact*, and *proposition*. Philosophers who define these terms become involved in the choice or development of complicated conceptual structures, just as do biologists in defining *life*, and anthropologists in defining *man*. Where, as in most cases, the terms in these structures are taken from everyday language, they are given clearly delimited meanings that contrast with their more loose employment in ordinary contexts. In their explicitly delimited use, terms are applied and propositions expressed by means of them being accepted or rejected according to the explicit commitments of the system. In their "ordinary" use, no such commitments are intended, and no choice among the alternative structures is made. Thus, if I say "I see a man coming," I may do so without having any definition of *man* (for example, Plato's) in mind; in speaking loosely, no such definition need be presupposed. Consequently, if I am asked to state exactly what my proposition is, I may answer, "Honestly, as far as I can judge, I did not have anything definite in mind. In regards to *man*, I never saw a definition I felt was a good one; on the other hand, I never really felt the need for a definition."

The "loose talk" Sextus engages in is in this way philosophically uncommitted talk, talk with rather little definiteness of intention relative to questions that are not of an everyday nature or that presuppose explicit conceptual frameworks. Its low degree of definiteness in fact renders "loose talk" incapable of location with respect to a conceptual system or frame that presupposes higher definiteness. An utterance such as "I see a man coming" may be perfectly appropriate even if it lacks a definiteness of intention such as would render it classifiable in relation to theological, existential, biological, or anthropological definitions of *man*. [The notion of the degree of a term's definiteness of intention will be elaborated later (see chapter 4, pp. 96–102).] But provisionally, we can identify what we mean by this phrase by noting that in talking about interpreting a statement not only do we use words that are inherently indeterminate or ambiguous—in that they can be used on different occasions

to say different things—but also on any particular occasion we may or may not have considered a variety of nonsynonymous interpretations of the words we use. Roughly, one utterance has less definiteness of intention than another if among a set of possible, nonsynonymous interpretations common to both utterances, it makes fewer discriminations than the other utterance. A “loose” expression is one that makes no discriminations in terms of explicit conceptual frameworks.

The Greek adverbs *adiaforos* and *adoxastos* are the main terms used by Sextus to suggest the peculiar looseness with which the sceptic puts forth the sentences by means of which he expresses his mind.⁹

Some of the apparently most absurd utterances thrown into dogmatic debate by sceptics acquire sense if interpreted in relation to definite conceptual frameworks. Consider, for instance, phrases relating to nonexistence, such as “Man does not exist,” “There is no such thing as position in space,” “No teacher exists,” and the like. We may assume the sceptic to intend expressions like these in relation to particular frameworks (those of the discussions he is witness to).

9. *Giving a message.* There are other forms of giving a message than reporting “as a chronicler.” Sextus uses a word (*apangellomai*) that leaves the question of technique of mediation open. The word may even cover utterances that the sceptic makes involuntarily—when he “accepts” appearances.
10. *Saying things.* Sextus lets the sceptic “say” (*fémi*) this or that in contexts where dogmatists would usually “state” or “assert” (using *lego*).
11. *Inclination to believe.* Sextus rejects probabilism, but sometimes uses terms to designate the inclination to believe one proposition rather than another (*pithanos* and *peitho*; see, for example, *Against the Logicians*, bk. 2: 473, 475). In mature sceptics, he takes these “natural” inclinations to be transitory states of mind.

The Dogmatic Ways of Announcement

1. *To opine.* Academic philosophers, says Sextus in the opening section of *Outlines*, have the opinion (*dokeo* —opine) that truth *cannot* be grasped, that it is inapprehensible (*akataléptos*). In general, to put forth as an

opinion, "to opine," is treated by Sextus as a nonsceptical way of announcement. It suggests that what one says is at least nearer the truth than the negation of what one says.¹⁰

2. *To grasp (as true)*. To say "I found that *p*," "I grasped that *p*," "I discovered that *p*," and the like, is even stronger than "I opine that *p*." It is to use a truly dogmatic way of announcement (*Outlines*, bk. 1, chap. 1). Sextus says that the Academician holds the opinion that he has *grasped* at least one truth, one true proposition, namely that there is not a single proposition (except this) that the truth of which can be grasped. As to this grasping, the basic metaphor seems to be that of obtaining a firm hold on something and keeping it securely in one's grasp.
3. *To affirm the certainty of what one says* (e.g., *Outlines*, bk. 1: 4). The Greek term here, *diabebaioumai*, is frequently used by Sextus (on behalf of the dogmatists). In denying that what it expresses has ever found a place in his own life, he may be said to be rejecting all claims of certainty, all guaranteeing (that it is so), giving assurance, or vouching—at least as far as *he* is concerned—relative to the truth of propositions. He does not predict that it will always be so, or that it must be so (as does the Academician). Even less does he claim that one can never, or should never, be certain, feel certain, have confidence.

If one explicitly says "It is certain that *p*," the prefix indicates the kind of claim made about "*p*"—it is one that includes the truth claim. Sextus means his comments to cover also cases in which the speaker manages to convey by other means that he holds *p* to be certain. Indeed, this applies to all the instances mentioned here: they cover not only the uses of *certain phrases* to express certain claims but also *the claims themselves*, however expressed.

4. *To posit as true, real, or really existent*. In opposing dogmatic opinions to one another, and saying that none is more credible than any other, Sextus says that the sceptic takes nothing for granted as true or real. The expression he uses here (*tithémi hós hyparchon*) probably implies truth or at least probability, whereas to pose or posit (*tithémi*) does not.
5. *To affirm one's conviction that what one says is true* (e.g., *Outlines*, bk. 1: 18). Sextus explains that the sceptic deals with questions concerning nature and essence in order to oppose (fight) dogmatic positions, not in order to say things with firm (certain) belief (*meta bebaion peismatos*).

6. To say *what a thing is by nature, in itself or in its essence* (*Outlines*, bk. 1: 20). Honey, says Sextus, seems sweet to us; we grant this, but whether honey *is* sweet—that is, sweet by nature, in its essence—is a subject for investigation. The honey’s sweetness is not appearance but something postulated on the basis of appearance.
7. *To settle* (*Outlines*, bk. 1: 197). Sextus defines “to settle” (*horizo*) in the relevant contexts not simply as to say something, but to put forward something nonevident with affirmation (*synkatathésis*). Bury translates the Greek word as “to determine.” In Latin translations we usually find *determinare*. “To settle” is a common meaning of *horizo*, however, and it suits the text where “determine” does not, either in the sense of “causally determine” or that of “define.”
8. *More worthy of belief*. Among conflicting judgments, no one is more worthy of belief (*pistoteros*) than any other. Although, as we have noted, Sextus does not adhere to any probabilism, some of the terms he uses may be translated by “probable,” but it is better to refer generally to inclination toward belief.

In conclusion, then, one may say that some phrases are taken to be exclusively sceptical, others to be exclusively dogmatic, and a third group comprises phrases belonging to both groups, but with different shades of meaning. It is important to point out, however, that the mere isolated use of a phrase with either sceptical or dogmatic intent does not in itself mean that the user is a sceptic or a dogmatist. There is also a time factor to take into account. Psychologically, scepticism must be considered a stable disposition, even if a momentary state of mind may hide it and even be inconsistent with it. Thus, a phlegmatic man may become momentarily agitated, and a mild man succumb to anger. Dispositions, however strong, are in this respect different from certain other states. The mentally blind, for example, may, under special circumstances, come to “see the light” in a way that has no parallel with the physically blind. Similarly, the sceptic may, under special circumstances, find something to be undeniably true, indubitable, absolutely certain. He does not then *suddenly* cease to be a mature, consistent sceptic. Only if the convictions persist does he leave the brotherhood of sceptics.

These reflections call to mind a passage in David Hume’s *Treatise* in which he apologizes for his very frequent lapses into a highly dogmatic style:

It is easier to forbear all examination and inquiry, than to check ourselves in so natural a propensity, and guard against that assurance, which always arises from an exact and full survey of an object. On such an occasion we are apt not only to forget our scepticism, but even our modesty too; and make use of such terms as these, *it is evident, it is certain, it is undeniable*; which a due deference to the public ought, perhaps, to prevent. I may have fallen into this fault after the example of others; but I here enter a *caveat* against any objections, which may be offered on that head; and declare that such expressions were extorted from me by the present view of the object, and imply no dogmatical spirit, nor conceited idea of my own judgment, which are sentiments that I am sensible can become nobody, and a sceptic still less than any other.

(Hume 1911, vol. 1: bk. 1, pt. 4, p. 258)

In assessing the extent of Hume's scepticism we should perhaps keep his caveat in mind, though one does so with certain reservations after reading Sextus Empiricus, who himself very rarely succumbs to dogmatic expressions. Certainly the style of "the greatest sceptic of modern time" is highly dogmatic in its use of extreme terms and its tendency to bring readers precipitately to far-reaching conclusions. One might have expected a publishing sceptic to tone down his antiseptical expressions when revising his manuscript or proofing it, but Hume gives little evidence of that. How, for example, could a sceptic conclude his ethical speculations with the sentence (Hume 1911, vol. 2: bk. 3, pt. 3, p. 310): "Thus, upon the whole, I am hopeful that nothing is wanting to an accurate proof of this system of ethics"?¹¹

There is, of course, nothing inconsistent in entertaining or expressing such a hope, but at the same time it is a hope to be rid of scepticism. Indeed, even the hope that one's system is more probable than just one other system envisages an end to one's Pyrrhonian or, for that matter, one's Academic scepticism. In order to understand the dogmatic style it is perhaps important to stress the least radical versions of the dogmatist's epistemological "scepticism," his probabilism, which permits very high, objective probabilities to be reached.

Neutrality Toward Subjectivist Phenomenalism

From a close inspection of the way of the sceptic, it is clear that he tends to avoid commitment to conceptualizations or conceptual frameworks; he will therefore tend to avoid any intellectualization of trust, confidence, and be-

lief in terms of the truth of propositions within such frameworks. Pyrrho's philosophy might therefore be called "anticonceptual" because his doubt concerning intellectual abstractions is so profound that he ends up without an explicit conceptual framework of his own. Pyrrho limits himself to undermining the conceptual frameworks of the dogmatists, without erecting any new one.

Many of the sentences and phrases used by Sextus, however, suggest adherence to a kind of phenomenalist and subjectivist position that we associate with the name of Descartes. If this were so, scepticism would be a kind of doctrinal philosophy; it would contain as an integral part a specific ontology, and it would adhere to a conceptual framework that allowed it to provide answers to questions with a high degree of definiteness of intention. It must therefore be an important part of the exegesis of our texts to see whether such a classification can be avoided without strain.

Occurrences of *fainomai* in forms other than the famous participle *fainomenon* are plentiful. In most cases, they have a rather general meaning, for example, "it seems," "it seems to me," "so it appears," "apparently," and "so it appears to us." What it is that appears, or seems, may be of very different kinds. In its first occurrence, that which is said "to appear to us" is that "Pyrrho applied himself to scepticism more thoroughly and conspicuously than his predecessors."¹² At another place, Sextus says that the sceptic uses the phrase "I suspend judgment" to indicate that things *appear* equal as regards to credibility and incredibility. In other connections, these "things" are defined as arguments; thus certain properties of arguments or of attitudes toward arguments are said to appear in certain ways. Quite often *fainetai* occurs where one would normally expect *esti* (etc.), that is, instead of "is." Something is said to appear, or appear such and such, in contrast to saying that it *is* such and such. Used in this way, it is clear that, conceptually, *fainetai* (it seems) does not imply that what seems must be sense data, sense impressions, subjective states, or the like. There are no definite limits to what can be said to appear and to appear so-and-so.

Subjectivity enters only in the sense that the sceptic does not claim truth, certainty, objective validity, or existence, but stresses that what he says is what *he* says, and that it bears witness to *his* state of mind *at that moment*. That is, he might say something different later or may have said something different in the past. It is what *appears* to him that guides him in his

daily life, not hypotheses or convictions about what is true. Accordingly, when the sceptic says "sweet," "this is sweet," or "honey, sweet," he does not intend to assert that honey as such—as the object perceived by him and others—is sweet in the sense of having that property by nature, nor does he intend to stress that what he speaks about is a sense impression of sweetness as opposed to an object causing or conditioning the sense impression.

The best interpretation seems to me to represent the sceptic as having a definiteness of intention no greater than that which we have in daily life when saying, for example, "honey, mm, yes, sweet"; that is, a definiteness not great enough to say that we intend to talk about a subjective impression rather than an intersubjective object, or vice versa. Confronted, therefore, with the philosopher's question "Is the sweetness in you or in the honey?" the sceptic can already apply his suspension of judgment. He does not side with the phenomenalist or subjectivist, who answer that sweetness is in the mind or consciousness or is only a phenomenon without its counterpart in the object, and so forth.

There are, admittedly, certain terms used by Sextus that are often translated in such a way that seemingly allow charges of phenomenism and subjectivism to stick.¹³ But if one takes these terms one by one, it is plain, I think, that no such translations are strictly needed, and that even if certain terms are used that generally express subjectivism in *philosophy*, they need not do so in everyday vocabulary. Thus, *feel* in "This is how I feel about it" need be no more subjectivist than "So it seems to me."

A further complication arises, however, from the use of expressions that do seem to suggest that the sceptic accepts the philosophical dualism between an external world or reality and internal states of consciousness and consciously limits himself to introspection. But the term translated by "external" (*exóthen*) (*Outlines*, bk. 1: 15) occurs in a context that does not imply that philosophical distinction. Two things are contrasted: giving a message concerning one's state of mind (Pappenheim's *sein eigener Zustand*) and affirming with certainty something about its grounds (i.e., something outside the state of mind and therefore not identical with it). In this terminology, anything beyond a present state of mind would count as "external" to this state, even if it were another state of mind—for instance, a belief one had as a child. There is no implication of externality in the sense of an external versus an introspected world.

In regard to “state of mind,” the everyday use of this expression does not imply any philosophical concept of states of consciousness. Sextus uses the term *pathos* for all that seems, including how one feels about certain arguments.

How the ideals of historians of philosophy change! To Robert D. Hicks (1910), the existence of a real world behind consciousness seemed to be a fundamental problem and neglect of it a tremendous handicap.

The scepticism of antiquity busied itself with the problem of knowledge. But when compared with cognate inquiries in modern philosophy, it appears in its scope and range almost ludicrously tentative, jejune, and superficial. That the object of cognition was external reality, nay more that it was material reality, was not in that age seriously questioned. No one ever challenged the existence of a real world of things lying behind the phenomena of which we are conscious.

(Hicks 1910: 312–13)

The implied criticism is that although Berkeleyan idealism (as traditionally conceived) had not yet been developed, a contemporary of Sextus should nonetheless have taken account of it. But there is no reason why sceptics should proffer arguments against distinctions and positions not yet developed by any dogmatists. And in any case, in suspending judgment about propositions concerning things (e.g., honey) that are said to have certain qualities (e.g., colors, tastes), the Pyrrhonist has made it sufficiently clear just how he would react both to an assertion and to a denial of an external world.¹⁴

The scope of Karl Jaspers’s penetrating *Psychologie der Weltanschauungen* (1954) leads one to expect a broad treatment of a variety of sceptical attitudes. But although there is some variety, it is unfortunately all mixed up with forms of nihilism. Friedrich Nietzsche and reactions to Nietzsche dominate Jaspers’s approach. Pyrrho’s answer to the question “How is the world?”—his worldview (*Weltbild*)—is itemized in seven dogmatic and sweeping statements (Jaspers 1954: 297). One of these is that we do not know and cannot know how the world is. Others represent Pyrrho as a phenomenalist and subjectivist in the modern philosophical sense. All in all, the sceptic, according to Jaspers, is a rather pitiable creature to be characterized mainly by what he lacks.

In the first book of *Against the Logicians*, sections 190–99, Sextus gives a detailed and very clear account of the Cyrenaic position. It is a marked

subjectivism, according to which one may infallibly make judgments about feelings (in the old sense of affective states). We can state with infallible certainty that we sense whiteness or sweetness, but we cannot grasp the objects producing these feelings or tell whether they are white or sweet. Feeling is the criterion: truths can be grasped, but only insofar as they describe feelings. Significantly, however, Sextus takes this doctrine to be an example of a dogmatic solution to the problem of a criterion of knowledge. That is, Sextus himself does not adhere to any of these solutions; he uses them as counterarguments. And he also brings arguments against the position that there can be a criterion.

It is therefore safe to conclude that scepticism, according to Sextus, does not embrace the subjectivism of the Cyrenaics or any other sect. Feelings, appearances, and sensations are not capable of furnishing a criterion of truth and validity, not even for a proposition that itself only describes an affection, appearance, or sensation.

So much is clear from the lengthy discussion by Sextus of criteria of truth and validity. Nevertheless there are passages in *Outlines* that are liable to be misunderstood. Thus, in one place Sextus seems to confirm that only one's own states of mind can be "grasped" (*Outlines*, bk. 1: 215). What one should do in such cases, however, is to give the passage an interpretation consistent with the rejection of any criterion, not to take it as proof of his belief in introspective certainty and knowledge.

Our conclusion, then, is this: Scepticism, if characterized by the seven-point account of its genesis, far from implying modern philosophical subjectivism, introspectivism, or phenomenalism, is at once more general, formal, and dialectical. In fact, the sceptic preserves his neutrality by not transcending certain everyday distinctions that may, but need not, lead to just such systems if worked out in relation to precise conceptual frameworks.

Indeed, it might be said that Sextus Empiricus's great contribution to thought was his indication of scepticism as a way of life, a way in which the embrace of doctrine is systematically avoided. If it is easy, as it has been customary, to praise him simply as an early expounder of more recent doctrines, or to see him simply as a useful source of philosophical theories, it is because one forgets or fails to see that these views were simply meant to be thrown into counterdoctrines likely to be held by his contemporaries. Consider, for example, Roderick M. Chisholm's (1941) evaluation of Sextus Empiricus:

His most significant contributions are: first, the positivistic and behavioristic theory of signs which he opposed to the metaphysical theory of the Stoics; secondly, his discussion of phenomenalism and its relation to common sense claims to knowledge; and, thirdly, his account of the controversy over the principle of extensionality in logic where the anticipation of contemporary doctrines is perhaps most remarkable. (Chisholm 1941: 371)

However, we have Sextus's own word that as a sceptic, whatever his own interest in the theories and doctrines current in his time, he himself subscribed to none of them. According to Chisholm's assessment, therefore, modern philosophers should be indebted to Sextus not for his careful statement of his own sceptical view, but for the detailed account he gives of the philosophical doctrines scepticism was exposed to at that time and of the arguments the sceptic used to combat them. Chisholm, however, sees Sextus not only as an expounder of doctrines, but also as a subscriber to them. Thus he attributes to Sextus the thesis that metaphysical objects (God, among others) do not exist "since we are unable to conceive anything which is non-empirical," and the doctrine that "indicative signs have no reference" (Chisholm 1941: 371), as well as claiming that Sextus opposed metaphysical statements on pragmatic grounds—that is, on the grounds that they were apt to engender futile controversy and would interfere with sceptical quietude.¹⁵

The close connection between twentieth-century empiricism and Sextus's Pyrrhonism is obvious. But it is unfair to portray Sextus as a supporter of any kind of doctrine stating that we have knowledge only of appearances or only of what is immediately given in experience. Phenomena in Sextus's terminology are indeed self-evident, but not in the sense of self-known. For we do not know anything simply insofar as something appears.

Chisholm remarks: "Although the sceptic does not deny appearances, he does deny the possibility of knowledge which refers beyond them" (1941: 377). It is a main point of Sextus's account, however, to make us understand that he neither denies nor affirms the possibility of knowledge, but lets the question remain open. It is true that Sextus does not deny appearances, in the sense of refusing to accept them; but he neither asserts nor denies *statements* such as "It is hot" or "I feel hot" or any other statement said to express what appears to him. Appearances are "beyond question" (*ibid.*), but not in the sense of furnishing or expressing knowledge. If they are beyond question, they are also beyond answer.

The Sceptic's Reference to the Existence of Opposite Views

Another misconception is that the sceptic's constant references to disagreements are a kind of argument, by appeal to particular cases, for a general conclusion that truth is beyond our grasp. Here we have both a misinterpretation of the sceptic's references to particular arguments and a miscalculation of his philosophical acumen.

The sceptic does not *expect* to sustain his *isosthenia*, he does not anticipate the outcome of an evaluation for and against, and his appeal to counterarguments is entirely ad hoc. Faced with a dogmatist who claims proposition *p* to be true, the sceptic's move would very often be to throw in the proposition "Not-*p* is true," and to suggest that the dogmatist defend *p* and attack not-*p*. But if the dogmatist now produces an argument, a pro-argument in relation to *p* or a counterargument in relation to not-*p*, it is natural for the sceptic to throw in what dogmatists with views different from the one he is facing have argued against. The enterprise is always experimental, to set one argument against another, and the origin of the arguments is itself of little importance. To find new, good arguments is no easy matter, and the sceptic cannot be blamed for making a start with those already available to him. It is therefore natural that in his works Sextus should constantly refer to disagreements between philosophers, listing different, more or less contrasting views on a great variety of subjects. But often he announces when he is leaving arguments found among dogmatists to offer arguments that have been invented by sceptics themselves.

Even painstaking students of Greek scepticism misjudge Sextus on this extensive listing of disagreement. Thus Victor Brochard (1887: 395) writes:

It is in its reasoning that scepticism fully reveals its weakness. It is clear, indeed, that there is only one condition on which the impossibility of the human mind's attaining truth could be legitimately inferred from the disagreement of opinions and of systems, namely that this disagreement could only be explained by the fact that there is no truth or that truth is inaccessible to us.¹⁶

But there is no inference of the kind "There is extreme disagreement between holders of opinions and systems, therefore it is impossible for the human mind to reach truth" to be found in Sextus's works. In the first place, the sceptic would not claim truth for either premise or conclusion separately, and second, he would not claim validity for the inference from premise

to conclusion. Suspension of judgment (cf. stage 4 in the sceptic's genesis) applies here too. If we found evidence of Sextus making the three claims, there would, of course, be reason to invoke the view so popular in accounts of Sextus that he was not very bright and most likely misrepresented greater sceptics.

Brochard's implicit view regarding the purpose of the selection of material referred to or quoted in the works of Sextus is a misrepresentation. The sceptic quite simply does not use disagreement as an argument for scepticism. He is much more tentative and judicious. He amasses arguments in the course of his perilous career. Although his counterarguments naturally tend to consist of already existing arguments—and in this sense he makes use of disagreements—he does not appeal to disagreement as such. He tries out counterarguments in concrete cases: a dogmatist asserts *p*, and the sceptic throws in, "How about so-and-so's counterargument *q*, against *p*?" This is very different from inferring the impossibility of finding truth from the existence of dogmatists holding that *p*, not-*p*, *q*, not-*q*, and so on.

Incidentally, it is also this failure to grasp the ad hoc nature of radical scepticism that underlies criticism that Sextus was a bad stylist and expositor. The translator of the Loeb Classical Library edition of Sextus's works, Robert Bury (1933, 1935, and 1936), remarks in his introduction that Sextus "wearies the reader by his way of piling argument upon argument for the mere sake of multiplying words—bad argument and good heaped together indiscriminately." However, it must be the uninformed reader Bury refers to, since he himself gives an excellent account of the character of Sextus's texts, indicating that they are not intended to be read word for word:

Obviously his books are not intended to be works of art, but rather immense arsenals stored with all the weapons of offence and defence of every conceivable pattern, old and new, that ever were forged on the anvil of Scepticism by the hammer blows of Eristic dialecticians. From these storehouses the Sceptic engaged in polemics may choose his weapon to suit his need; for (as Sextus naïvely observes) the Sceptic is a "philanthropic" person who spares his adversary by using against him only the minimum of force necessary to bowl him over, so that the weakest and most flimsy arguments have their uses as well as the weightiest.

(Bury 1933 : xlii)

This corresponds exactly with the interpretation I am proposing, except that it is difficult to see why Sextus should be considered naïve in his account of the sceptic's manner of arguing. Not only does it fit in very well with other

things he says, but even today meeting arguments with sufficiently strong, but not more than sufficiently strong, counterarguments is a sophisticated procedure. The kinds of arguments used depend on the status of discussion at the time at which the sceptic throws the argument into the debate (without participating in it). Therefore, a sceptical manual would need constant revision, new editions coming out from time to time. But no "bad" or weak argument should be left out if it is adequate in a given situation. Accordingly, Sextus's manual should not be read as a Platonic dialogue but as a reference work to be consulted at appropriate moments. As such, it is well compiled and efficiently enough organized.

Of course the procedure of considering every argument on its own merits is characteristic of all critical philosophy. It is in his continuing and pervasive suspension of judgment that the Pyrrhonist differs from the ordinary critical philosopher. And it is in this apparently willful refusal to believe or accept anything that those otherwise sympathetic with the Pyrrhonist's procedure have found the absurdity or impossibility of his brand of scepticism. If only this perverse element were removed, the critical philosopher would find in the Pyrrhonist a brother in arms. Thus Hume (1951), who denied that there could be "any such absurd creature . . . who had no opinion or principle concerning any subject," allowed that a moderate scepticism "may be understood in a very reasonable sense, and is a necessary preparative to the study of philosophy."

Bertrand Russell (1967), too, has favored a criticism of knowledge that is not "the attitude of the complete sceptic." Absolute scepticism is unreasonable; rather it is "Descartes' 'methodical doubt,' with which modern philosophy began . . . [that is] the kind of criticism which we are asserting to be the essence of philosophy. His 'methodical doubt' consisted in doubting whatever seemed doubtful; in pausing, with each apparent piece of knowledge, to ask himself whether, on reflection, he would feel certain that he really knew it." Such criticism, thinks Russell, constitutes philosophy. But there is some knowledge, for example, of the existence of our sense data, which to him appears "quite indubitable, however calmly and thoroughly we reflect upon it. In regard to such knowledge, philosophical criticism does not require that we should abstain from belief" (*ibid.*, p. 87). We should not reject "the beliefs which do not appear open to any objections, however closely we examine them" (*ibid.*, p. 88).

Russell's exposition is convincing only so long as he refrains from giving examples of the kind of conclusive knowledge he means, that is, so long as he abstains from applying his principle concretely. However, the various concepts of sense data are of course highly controversial, and calm and thorough reflection is apt to disclose that any highly conceptualized belief in sense data is indeed open to objection, especially when made precise in its relation to conceptual frameworks of psychology and epistemology. What Russell seems to imply is that beliefs that are not open to any existing objections are not open to any objections.

Of course, the complete sceptic in Russell's terms cannot be the Pyrrhonist according to Sextus; the Pyrrhonist would not require us to abstain from a belief to which we could find no objection, however calmly and thoroughly we reflected. He would simply contend that he had not, as yet, come across a belief based on an established truth. Should he find such a true belief, of course, his suspension of judgment could no longer be sustained by a balance of arguments, and he could then no longer be a sceptic of the kind described. Being a sceptic of that kind, he could *not* have found a belief immune to objection.

The continuation of Russell's account, on the other hand, could be safely acquiesced to by the Pyrrhonist.

The criticism aimed at, in a word, is not that which, without reason, determines to reject, but that which considers each piece of apparent knowledge on its merits, and retains whatever still appears to be knowledge when this consideration is completed. (Ibid., 88)

If there is nothing left over, nothing will be retained.

The Mature Sceptic: A Moderately Keen Seeker and Doubter?

If the sceptic's suspension of judgment regarding the finding of truth must be based on his failure to, as yet, find decisive arguments for or against, the question arises as to how much we should expect of the sceptic in his efforts to overcome this failure. Are there minimum requirements? In cases in which the sceptic takes no steps at all to find arguments, might not his failure to be convinced be a matter for reproach? Should we not regard him as a sceptic only by default?

Here we must first recall that an essential feature of the sceptic we are describing is his openness of mind. According to stage 7, *he is a seeker*, and since this, like the ad hoc nature of his scepticism, is a matter of definition, it is acknowledged that we are in any case concerned with someone who shows a degree of interest in finding truths. Consequently, our sceptic cannot be accused of evading the issues. He is not continually racking his brain for arguments—as indeed is unlikely in the case of one who does not expect to find the truth—but he must at least be open to argument and even to conviction. Arguments always interest him, and if he is someone who does not expect to find the truth, this is only because past disappointment has destroyed his previous optimism about finding it. It is no part of the definition of the sceptic that he is constitutionally either unprepared to face decisive arguments or impervious to their force.

The question remains, though, as to whether openness itself is enough. The normal view is probably that it is not, for the sceptic is normally conceived as a doubter. Indeed, it is thought a valid objection to scepticism that one *cannot* persistently doubt all that the sceptic doubts. To be a sceptic, according to this view, is necessarily to be in a perpetual state of indecision; a moment's confidence or certainty is enough to burst the fragile bubble, to disqualify one as a sceptic.

But there is no reason why we should think of the sceptic in this way, as one who should, ideally, hesitate before every step in order to question whether the assumptions on which it is based are valid. Indeed, before raising such a question, the sceptic would want to know what the assumptions were, or whether there were any, and what was meant by *assumption* in this case; and insofar as answers to such questions involve explicit and more or less complicated conceptualizations, all of this would go beyond what the sceptic felt he had any settled opinion on. Any display of confidence, as far as he is concerned, may or may not be a matter of assumptions. At least it is not obvious that the sceptic must avoid trust and confidence, or that his behavior must be characterized by doubt and indecision. Perhaps, as we shall see in the next chapter, there is no real call to consider the sceptic a doubter at all.

There is nothing particularly vital in our terminology at this point. It could be perfectly reasonable to retain the image of a sceptic as a doubter rather than a truster; this itself will not lead to misconceptions as long as one remembers that in the history of thought, the greatest sceptics were

also great champions of trust and confidence and of common sense *in action*—however brutal they were in criticizing ordinary thinking in its use of the notions true or false, valid or invalid.

In answer to the question of what and how much we should expect of the sceptic, I see no grounds for asking more of him than of dogmatists. A man who adheres to the doctrines of Plato, Spinoza, or Kant, or has a more or less individual outlook of his own, and who makes truth claims or claims of objective validity, is open to criticism if he does not from time to time consider and reconsider arguments against his position. But it would be preposterous to ask him to do this daily, especially if he is not a professional philosopher.

Applying the same norms to the sceptic, one must surely allow that the exercise of suspension of judgment as a mental act need not go so far as to completely color the sceptic's private life. There is no need for him to consider judgments involving truth claims every day and come to the result that there is no decisive argument pro or con. Although there will certainly be occasions for suspension of judgment, there will be no constant need for it.

Similar considerations apply to the sceptic as a "seeker." He is counted a seeker because he has not found truth but leaves open the possibility of finding it. Nothing is prejudged in the idea of his openness about how eager he should be to find the truth in any definite matter. Indeed, as we suggested, his main noncognitive motivation for finding truth is no longer there: the peace of mind which he was seeking is already found. There remain cognitive and practical motivations, and the strength of these may vary among different sceptics.

The basic complaint of the Pyrrhonian sceptic against all others (the dogmatists, including the Academicians) is that they are guilty of rashness (haste, recklessness, *propeteia*). They leap precipitately to conclusions about truth, falsity, knowledge, or certainty. As against this, one should *wait* until arguments for are decisively stronger than arguments against, or vice versa. (In order not to be accused of dogmatism, the Pyrrhonist will refrain from claiming the truth or objective validity of any point in the logic of argumentation. He speaks about his own behavior in discussions in terms of propensities, and the like. Among the examples of rashness Sextus mentions is that of deciding on the question whether something can be grasped—with certainty—or not [*Outlines*, bk. 1: 237].)

Since the sceptical phrases we have mentioned are expressive of the sceptic's state of mind when confronted with dogmatists, it is doubly misleading to say without qualification, as Brochard does (1887: 332), that their function is to "express his doubt," and to portray the sceptic as being more in doubt than others. It is important to distinguish doubting from suspension of judgment. Suspension of judgment is the basic trait of the sceptic when confronted with dogmatic assertions. The question of how much, how often, and in what sense doubt must, or is likely to, accompany or precede the suspension of judgment, is an open question. There is no reason at all to postulate a *state of doubting* as characteristic of the mind of one who suspends judgment. Suspension here is not a process; it is an absence of judgment concerning truth. Yet it is just this identification of doubt with suspension of judgment that so often mars references to the Pyrrhonic sceptics. Not that in the genesis of a sceptic, doubt and indecision play no part; indeed, the gifted people in Sextus's narrative were led to scepticism precisely by the disquieting doubt and indecision induced in them by the contradictions in things, and the *ataraxia* that Sextus describes is intended as a means of eliminating just that state of disquiet.

The Sceptic: A Philosopher?

For every hundred references in the literature to Academic scepticism (negative dogmatism), there is scarcely one to Pyrrhonism as described by Sextus. And of the many references to Pyrrho and Sextus, few do not hint at negative dogmatism.

One main reason for this is an apriorism and universalism that has deep roots in nearly all philosophical literature. Because the sceptic does not state a priori that knowledge cannot be reached, that knowledge is impossible, or because he does not adduce arguments against the possibility of knowledge in general—but only throws in particular arguments against particular knowledge claims—he is not counted a real philosopher. Instead, he is summarily referred to psychologists and psychiatrists. Because he does not meet them on their own battlefield—apriorism and universalism—real philosophers are not supposed to worry about him.

To be fair, the philosophers have a stronger point: the sceptic of the pure Pyrrhonist community ventures no proposition whatsoever that in-

cludes a truth or probability claim. Surely a person who is propositionally mute places himself outside the philosophical community. Or does he? If a sceptic has developed his suspension of judgment and has thrown in arguments against all the philosophical doctrines of his time, the philosophers may still refuse to take his scepticism seriously simply because the sceptic does not claim that he will continue to retain his attitude. Scepticism seems to be ad hoc, provisional, transient, or even spasmodic.

There are two answers to this. First, adherence to any doctrine is liable to lapse. However certain a Spinozist or Neothomist may be that he will never alter his views, a change is not precluded. The sceptic, of course, declares nothing. But why should this make a change more probable in his case? Why does the ad hoc nature of scepticism need to affect the matter—the mature sceptic says no more than that *up to now* he has not been brought out of his *epoché*, but that this might well occur at some time in the future. The fact that the sceptic is more willing than most to acknowledge the possibility of his own defection does not make this event more likely in his case than in others. Second, scepticism does not really deserve to be called provisional, transient, or spasmodic, because there is nothing in it that conceptually supports these characteristics (and when we come down to considering views in terms of the actual behavior of their exponents and adherents, we find that any bent of mind may spend itself or wither and any doctrine be abandoned or transcended).

There is no argument that is *specifically* antisceptical. When the sceptic throws an argument into a philosophical debate, and a philosopher finds it worth consideration, the sceptic may support it or fight it with a set of arguments. In doing so, however, he argues neither for nor against a general sceptical “position.” But if he tends toward *isosthenia*, his development may well continue in the way described by Sextus, and he may end up as a mature sceptic (in our terminology).

As to whether scepticism counts as a philosophy, if we accept as a necessary condition of philosophy that the thing considered must contain at least one proposition or at least one doctrine explicitly claimed to be true or probable, then scepticism is not a philosophy. The question is largely terminological, but even if we adopted this not at all traditional way of speaking, there would still be room for calling scepticism a basic philosophic attitude or an existential-philosophy (with a hyphen!), and the sceptic a (genuine) philosopher.

Philosophical tradition embraces philosophers whose "philosophy" does not contain a single proposition with a truth claim, or at least whose program or intention was of that character. From and including Socrates, there have been propositionally innocent philosophers through all periods up until the logical empiricists and various Anglo-American movements inspired by Wittgenstein. It is a commonplace in various quarters that philosophy is really a kind of activity—for example, that of clarifying meanings. And although logical empiricists mingled with scientists, they insisted that as philosophers it was not up to them to take a stand for or against propositions in the nonformal sciences, whereas the formal sciences, for their part, were so conceived as not to contain any propositions.

But terminology may not, after all, be very important at this point, and so long as we may call scepticism a philosophical attitude or existential-philosophy, and its articulate representatives philosophers, I shall not insist that Pyrrhonic scepticism be called a philosophy. Perhaps "an ingredient of a philosophy" would be an apt description since the genetic characterization may be satisfied by persons showing deep differences in outlook and basic attitudes.

It is pertinent to ask whether the sceptic has ever explicitly questioned his own at least implicit acceptance of the distinction between true and false. The mature sceptic sees how in everyday life people use "I know that *p*," "*p* is perfectly certain," "I cannot be mistaken" in a very loose fashion, with an extremely low standard of evidence compared with that required, for example, in geometry. He himself is also a great exponent of loose talk insofar as he is conceptually unpretentious and without any definite conceptual framework. Why, then, does he apparently not join in the *loose* use of the terms *true*, *certain*, *real*, and *known*? It must be that his development has somehow made these terms stand out separately from the rest. Because of this, he can honestly say that as a mature sceptic he is "still seeking." For he has retained conceptualizations of *true*, *certain*, *real*, and *known* that permit him to suspend judgment in cases in which everyday uses of the terms would force him to exclaim "This is true!," "This is perfectly certain!," "This is how the thing really is!," or "This I know!"

Suppose, however, that a sceptic were to give up these remaining conceptualizations of the seeker, the zetetic; what kind of philosophy would one have then? The sceptic, it seems, would cease to be a sceptic and come

close to being a later Wittgensteinian, at least according to one main interpretation of Ludwig Wittgenstein's *Philosophical Investigations* (1958).

According to that interpretation, there already exists a definite "logic" of the terms *true* and *known*, and this logic is such that there are a great many things we know perfectly well; for the language we use does not provide room for meaningful doubt here. Moreover, a science of language, a conceptualized doctrine *about* the logic of these terms, is not needed because the pertinent facts can be shown, pointed to. Because philosophy leaves everything as it is, its conceptualizations, including the distinctions between true and false and between known and unknown, cannot result in any change in the logic of the everyday use of the terms it has borrowed.

In regard to what evidence we require in order to know, there is a term *conclusive evidence* that also has its own logic of use. This can be shown by asking, *When* is it *legitimate* to say "This evidence is conclusive"? The question "Is evidence ever conclusive?" cannot be raised. The distinction between conclusive and nonconclusive is already built into the language, and this implies that there is a proper use of *conclusive* as well as of *inconclusive*. So if someone were to come and say that in every case in which *conclusive* has been used, *inconclusive* was the appropriate term, he would clearly violate the existing logic of the distinction.

Thus, the mature sceptic is only a partial conformist; he inevitably encounters opposition when responding sceptically to requests to subscribe to the absolutes of his community—the proclaimed truths, the propositions everyone *knows* must be true. The Wittgensteinian in the above interpretation, on the other hand, is an enlightened, but total, conformist. Even when it comes to the basic zetetic terms, he asks, What is it *legitimate* to say? What am I *justified* in saying? What are the standards of the community in assessing evidence? What is *socially* acceptable as conclusive evidence?

Although the mature sceptic does not participate in the philosophic debate, we have seen that he nevertheless throws arguments into it. He does not rule out the possibility that he will eventually become a participant—if a dogmatist can convince him of the truth of at least one proposition. In any case, he accepts the concepts and arguments of dogmatists as meaningful and their views as possible views. Although the Wittgensteinian portrayed above resembles the mature sceptic in not participating in the debate, in all other respects the difference is profound: The Wittgensteinian does not

throw in arguments, and he definitely rules out the possibility of active participation. He also does not accept the concepts and arguments of dogmatists as meaningful, and he rejects the possibility of their views being true doctrines.

Defining Scepticism

In this chapter we have tried to clarify certain distinctions made by Sextus that are vital to a grasp of the significance of Pyrrhonism as a philosophy or a philosophical attitude. These distinctions, between Academic scepticism and Pyrrhonism, between sceptical and dogmatic ways of announcement, and between suspension of judgment and doubt, all play an important part in the credibility of Sextus's portrayal of the sceptic. From the few but typical references to Sextus in this chapter, it will be seen how far extant accounts and evaluations are from taking what he says seriously. Perhaps it is the prevailing philosophical preoccupations, now and in the past, that have done Sextus the greatest disservice by obscuring the value of the distinctions that he is at pains to stress. Consequently, Pyrrhonism tends to be regarded as an extreme scepticism, at best an impracticable ideal, and to be classified along with other less radical, but supposedly more possible, forms under definitions that take little account of what Sextus actually wrote. This is true even of Richard H. Popkin's formulations of scepticism in his excellent contribution to the *Encyclopedia of Philosophy*. Popkin (1967: 449) opens, as is traditional in encyclopedias, with a vague formulation suggesting some kind of definition: "Skepticism, as a critical philosophical attitude, questions the reliability of the knowledge claims made by philosophers and others." But such a formulation fails to do justice to Pyrrhonism. Pyrrhonism is not just an attitude of epistemological questioning; any adequate conception of the kind of questioning that it is must take account of the distinctions we have mentioned, as well as such aspects as *ataraxia* and trust.

Popkin's next, more precise, formulation, that philosophical sceptics "have questioned whether any necessary or indubitable information can actually be gained about the real nature of things" (*ibid.*), though applicable to Pyrrhonism and some other forms of scepticism, applies equally to any philosophy that criticizes necessity and indubitability or concepts of real

nature. Carneades, on the other hand, was a sceptic who, although he questioned necessity, and perhaps also indubitability, seems to have believed in differences in probability. It is clear—and of course Popkin does not deny this—that the appraisals and arguments appropriate to probabilists differ greatly from those that apply to Pyrrhonian scepticism.

Popkin continues: “Skeptics have organized their questioning into systematic sets of arguments aimed at raising doubts” (ibid.). But for the Pyrrhonian sceptic, as a seeker of truth, it would be inappropriate to mention a specific aim of any kind, except perhaps as just one of a cluster of aims. It is true that the mature sceptic tends to influence the dogmatist in the direction of scepticism, and this may take the form of inducing him to doubt. However, in doing so, he is only following his so-called natural impulses of sympathy, as Sextus would say in his capacity as metasceptic. As for his own future, the mature sceptic is naturally on the lookout for decisive arguments that might bring his scepticism to an end. But here the listing of arguments should, strictly speaking, be regarded as having the heuristic aim—if it can be said to have an aim at all—of eliciting new and better arguments through which to preserve his *ataraxia*.

Finally, in formulating a notion of extreme scepticism, Popkin says: “Extreme skepticism questions all knowledge claims that go beyond immediate experience, except perhaps those of logic and mathematics” (ibid.). Sextus and others, however, have questioned even logic and mathematics. If my previous analyses are adequate, the Pyrrhonian questions all knowledge claims, including those that, in a more recent terminology, may be called “knowledge claims that do *not* go beyond immediate experience.” The Pyrrhonist “acquiesces in the appearances” not because of any truth or adequate cognitive status that he attaches to the “angelic” messages that convey the appearances, but because such messages convey no knowledge claim at all. A scepticism that contains knowledge claims of or about immediate experience is not an extreme scepticism, at least along one dimension of comparison. But of course a main difficulty in the way of any attempt to delimit an extreme scepticism is the low degree of comparability of extremes of scepticism along the different dimensions that we referred to at the beginning of the chapter. A scepticism that makes no positive claims at all might, for example, be thought to be less intense than one that denied the possibility of knowledge beyond immediate experience—for at least

PYRRHO'S SCEPTICISM ACCORDING TO SEXTUS EMPIRICUS

the former scepticism allows for a possibility that the other rejects. Perhaps the word *extreme* is best avoided; it would certainly be very misleading to describe the Pyrrhonist himself as an extremist of any kind. It might be appropriate, on the other hand, to regard him as a radical, for his scepticism, if not extreme, is extremely thorough and consistent.

II

The Psychological Possibility of Scepticism

Introduction

One of the most common objections leveled against scepticism is that however consistent it is in itself, it cannot be serious. Sceptical doubts are not real doubts but only theoretical. Furthermore, it would be impossible to put sceptical theory into practice, for to be consistently sceptical, so it is held, would be to sentence oneself to a life of inactivity; as soon as one begins to do something, one begins to take certain things for granted, to believe in them and hence not to doubt them.

The assumption that scepticism, though rational, is patently untenable is fairly widespread and sets the pattern for much contemporary discussion. For example, Alfred J. Ayer (1956: 78) in *The Problem of Knowledge* writes: "No doubt we do know what [the sceptic] says we cannot know, we are at least called upon to explain how it is possible that we should." From this perspective, the problem of knowledge has become the problem of explaining—in the face of the so-called sceptic's arguments to the contrary—how knowledge is possible. In other words, scepticism is identified with an argument to be rebutted if we are to justify our claims to know anything at all. The sceptic is a good logician, but somewhere or other there must be a flaw in his argument, either in the process of reasoning or in his premises. For what could be more obvious than that there are at least some statements that we know to be true? And what could be a more obvious demonstration of the sceptic's de facto acceptance of this fact than his actual linguistic and nonlinguistic behavior?

Is Scepticism More Logically Than Psychologically Impeccable?

Some contemporary philosophers advance this objection by saying that (what they call) scepticism, though logically consistent, is psychologically im-

possible: a person can pretend to be, but cannot really be, a consistent sceptic. The most famous exponent of this view, Bertrand Russell, has himself been intimately and personally engaged in questions of scepticism. He puts the matter thus: "Scepticism, while logically impeccable, is psychologically impossible, and there is an element of frivolous insincerity in any philosophy which pretends to accept it" (1948: 9; cf. p. 196).

However, Russell, in line with most recent discussions of scepticism, is thinking here not of the sceptical way of Pyrrho, as outlined by Sextus, but of a narrow and much less radical trend of sceptical thinking that he terms "sceptical solipsism."¹ Russell finds that it is psychologically impossible in practice to doubt the existence of other minds and of the external world. But in coming to this conclusion, he applies concepts of "other minds" and "external world" that presume a dualism of a particular and not altogether uncontroversial kind.² The Pyrrhonist, however, is not bound to join issue on the question of the existence of other minds or of the external world as conceived by Russell, insofar as these concepts presume a dualism that he sceptically declines either to accept or reject. If he says "The stone is hot," he will not, in the normal course of events, implicitly distinguish between an internal and an external world and on the basis of this distinction locate the stone's heat either in the external world, as opposed to, say consciousness, or in an inner mental world. If led into a discussion about whether the heat really resides in the stone or in the mind, he remains unperturbed, declining to offer judgment. It must be remembered that the most important effect of the sceptic's *epoché* is to insulate him from philosophical discussion. Such discussion, to be technically satisfactory, must be relative to certain conceptual frames, that is, to systems of definitions involving clear-cut distinctions and rules for interpreting the key terms, and these must be adopted in order to get a discussion *pro et contra* going. By maintaining an *epoché* in relation to conceptual frameworks, the sceptic simply refuses to get going.

Sextus's picture of the sceptic is thus quite different from Russell's insofar as the Russellian sceptic is apparently unable to let himself trust and have confidence in a crude everyday realism into which such sophisticated problems as these do not intrude. Such trust and confidence at the philosophically uncommitted level is, of course, precisely what we would expect from the Pyrrhonian sceptic, at least if we are to take Sextus seriously when he characterizes the "loose" ways of talking employed by the sceptic in expressing his mind undogmatically (cf. my discussion on pp. 9–11).

The formula "Scepticism is logically impeccable but psychologically impossible" therefore fails to do justice to the strengths and weaknesses of Pyrrhonian scepticism. Indeed, if the foregoing exposition and interpretation are correct, we should be entitled to adopt a very different formula: "Scepticism is psychologically impeccable and logically invulnerable."

The thesis that scepticism is impeccable psychologically—in other words, that it is psychologically possible, perhaps even in some cases desirable, to be a sceptic—may seem harder to defend than the thesis that it is logically invulnerable. To be susceptible to charges of inconsistency, scepticism would have to include at least two contradictory propositions; but, as we have seen, it includes no propositions at all. Scepticism is not inconsistent, but it is not consistent either. The question of inconsistency is not so easily disposed of however. As we shall see, the criticism that scepticism is psychologically impossible in part depends on the supposed objection that whatever the sceptic may or may not say, his actions betray implicit allegiance to beliefs and assumptions. In short, these actions falsify the description of him as a person who suspends judgment on all things.

Do the Sceptic's Actions Betray His Dogmatism?

It is objected that by persistently withholding judgment sceptics fly in the face of their own experience and practice. The basis of the objection is that any display of acquiescence or confidence on the part of the sceptic is tantamount to his acceptance of some proposition.

Thus, for example, the mere fact that I stride confidently into a room might be said to be tantamount to accepting the proposition "This floor will bear my weight"³—in the same way that quickly withdrawing my foot after ominous creakings might be regarded as tantamount to my rejection of the proposition, or that setting each foot down tentatively and with great hesitation might be regarded as tantamount to my withholding it.⁴

According to this assumption, the Pyrrhonist's behavior would be the measure of his ability to remain a sceptic. Despite his failure to make positive or negative assertions, there would still be a basis for attributing inconsistency to him; for his actions would imply propositions, and the manner of his actions would determine his epistemic attitude toward the propositions. If not necessarily inconsistent, the sceptic would remain sceptical only so long as he remained hesitant. And the world and human nature be-

ing what they are, he would be prone to so many frequent lapses into dogmatism that to describe him as generally sceptical rather than dogmatic would be misleading, to say the least.

This argument might be given stronger forms. To act at all, it might be said, involves some belief or other no matter how diffidently one behaves. One cannot act consciously without implicitly accepting the truth, at least temporarily, of some proposition. For example, whatever one's reservations concerning the strength of the floor, one accepts that one has such reservations. If and when they are borne out, one will tend to move downward rather than upward, and if one intended to achieve something by setting feet on the floor—other than, say, merely testing its strength—then this cannot be achieved exactly in the way one was hoping it might. According to this stronger objection, the consistent Pyrrhonist would be resigned to a life of complete inactivity. There might, however, be an even stronger form of the argument in which it is claimed that the very act of contemplating oneself and one's own inactivity would require implicit acceptance of propositions. If the argument were sustained, the sceptic, so long as he was conscious, could never free himself from a fundamental dogmatism.

What is the relation between acquiescence and confidence, on the one hand, and the acceptance or rejection of propositions on the other? Let us take up this question by considering the relation between action and belief.

If a person claimed to hold certain moral beliefs, for example, and made no move to act in conformity with them in situations in which the beliefs were clearly applicable, his claim would be justifiably disputed. And if a navigator claimed to believe that the earth is flat and continued to employ calculations and instruments whose proper use he acknowledged depended on the assumption that the world is round, he would be justifiably suspected of being less than honest about what he believed. Thus, it does seem that a person's behavior can tend to show whether he indeed has those certain beliefs he professes to have. Moreover, with beliefs implying some fairly specific patterns of behavior, the absence of action falling into such patterns will, saving exceptional circumstances, not only tend to show but also conclusively reveal the absence of the corresponding beliefs.

Some, like Gilbert Ryle, would assert that believing is never merely "propositional," but a matter of being prone to *do* certain things; just as believing that the ice is dangerously thin is not simply a matter of telling oneself and others that it is so, or of acquiescing in the assertions of others

to that effect, but also “to be prone to skate warily, to dwell in imagination on possible disasters and to warn other skaters” (1949: 135). If “proneness” is to be understood behaviorally, the matter is settled; but even without that we can say that if to believe something is at least in part to be *disposed* to do this rather than that, then, lacking the relevant dispositions, one would not have the belief.

The question now is whether it also follows that if one does not have the belief, one cannot act in the manner of a person who does. For if it does follow, then the sceptic is debarred from all behavior that can be construed in terms of beliefs and their corresponding dispositions. What William James said of religious belief would apply to all meaningful activity. James stated that “since belief is measured by action, he who forbids us to believe religion to be true, necessarily also forbids us to act as we should if we did believe it to be true” (1957: 108 fn.). If this were to be applied generally, not to believe in the truth of something would be to deny oneself the chance to engage in whatever actions were consequent upon the belief in its truth.

There is a context in which one may be said to act in the manner of someone who holds a certain belief when in fact one is merely pretending to have that belief. Here, acting in the relevant manner is not only allowed but, one would suppose, positively required. However, the sceptic can hardly be let off on the supposition that he is pretending to hold beliefs. Generally speaking, his actions must be seen to arise from genuine dispositions, from proneness, and so on. In pretending to have a belief, on the other hand, it is precisely the *absence* of the relevant dispositions that the behavior is supposed to hide. What we need to ask, therefore, is whether it is possible to have the dispositions to act in certain ways without having the relevant beliefs that generally accompany them.

The notion of experimentation may help us here. Why should one not be able, for example, to try out beliefs much as one tries on clothes? And try them out to the extent of “putting on” the appropriate dispositions? The experimentation, while it lasted, could be indistinguishable, at least externally, from actual commitment to the beliefs, and the experimenter himself might even become, temporarily, another kind of person, finding himself talking and acting in different and not always premeditated ways—ways that, planned or not, he would nevertheless say he was not committed to and did not “own.” Thus, however much the experiment might resemble the real thing, the experimenter himself does not lose sight of the experimen-

tal nature of the exercise and, most importantly, while experimenting, he is *ex hypothesi*, not yet committed, not yet content.

But how far can the sceptic be understood as an experimenter? If we recall our earlier definitions (see pp. 3–6) of the Pyrrhonist, it may seem that he cannot be regarded in this way at all. We said, for instance, that he found no better grounds for accepting the arguments in favor of a doctrine than for accepting those against it. But the experimenter will surely begin his search by selecting the likeliest candidates among the propositions available to him, at the very least preferring some proposition or other to its negation. Thus, to act experimentally would seem to require a preference for propositions whose grounds for potential acceptance do seem stronger than those for potential rejection. To accord with this account of the Pyrrhonist's suspension of judgment, then, the required analogy would have to lack any purposive and selective component; in terms of the clothes analogy, we would have to compare the Pyrrhonist's assumption of beliefs to a person putting on clothes for amusement and without any serious thought to their style, quality, or general suitability. But this kind of transaction with beliefs could hardly explain the sceptic's continued adaptation to, and confidence in, the world around him.

Sextus, however, defines the sceptic's suspension of judgment as a state of mental rest owing to which he neither denies nor affirms anything (*Outlines*, bk. 1: 10), and we said the sceptic (cf. pp. 4–5) was one who has so far not found sufficient weight of arguments *pro* or *contra* to justify a decision about what is true or even about what is probable. But if he has not yet been able to decide what is probable, surely he must have been equally unable to decide, in the case of any proposition, that it and its negation are *equally* probable? In that case, how can the sceptic find that the arguments for a proposition are no stronger than those against it?

That Sextus is not inconsistent here becomes clear when one realizes that in finding a balance between arguments for and against, the sceptic is not arriving at some calculation of the respective weight of the arguments he has arraigned for and against a proposition and on the basis of this calculation justifying his disinclination to offer judgment. It would be as incorrect to interpret the Pyrrhonist in this way as it would to say that in failing to find any arguments strong enough to convince him, he is measuring them against some standard that they must conform to before he will accept them. His suspension of judgment is not based on some specifiable short-

coming in the arguments presented to him; nor is the balance of the arguments something that he works out according to any theory or rule of thumb. The fact that he does not find the arguments for a proposition strong enough to overcome the force of the arguments against it consists in nothing more than the fact that he, personally, is not impelled by them sufficiently to be able to discount the force of the counterarguments. The sceptic refrains from affirming or denying simply because to stand firmly by some proposition or its negation would be to forfeit an option he feels he must retain if he is to preserve his peace of mind. He is the kind of person who if he affirms or denies something opens himself to the very doubts that led him in the first place to favor suspension of judgment. As we remarked earlier, the question of the possibility of scepticism is really no more than the question of the possibility of there being such a person.

Sextus talks of the sceptic as one for whom the balance between *pro* and *contra* is not disturbed (see point 3, p. 4). It would seem quite possible for the more inquisitive and venturesome sceptic who is willing to take a chance with his scepticism to prefer one proposition to another, experimentally, without disturbing the balance. The only relevant measure of whether, and how far, a sceptic can do so is the absence on his part of compulsion toward one side at the expense of the other. The degree to which he can safely experiment with a belief without succumbing to it, and hence forfeiting his option, will be a matter of his personal psychology.

But the main difficulty is that not all a sceptic does can be regarded as experimental. To be able to experiment with a belief, one must first have considered the belief as a possible truth. But what about all those actions that actually cannot correspond to beliefs adopted in practice simply because they are not adopted—because they do not even correspond to envisaged possibilities? The sceptic who walks into a room may or may not be experimenting with the belief that the floor will support him, but when he brushes sweat from his brow, after having crossed safely to the other side of the room, he may very well be expressing relief that undesirable possibilities were not realized. Such actions could not usually be said to correspond to envisaged possibilities, but they would have to be viewed as envisaged possibilities before the sceptic could be accused of being unwilling to stand by the beliefs they imply. Thus, the explanation of the sceptic's actions as experimental does not support a general defense of the possibility that the sceptic is continuing to act as if he believed in certain truths. Whatever the

THE PSYCHOLOGICAL POSSIBILITY OF SCEPTICISM

sceptic says, or does not say, his own more or less unconscious acts speak for themselves and proclaim his beliefs. But if his actions say what he himself will not say, his silence is wholly gratuitous.

But why should a person's more or less unconscious acts be described in terms of the adoption of beliefs at all? Why should a person's unquestioning behavior be understood as putting him, so to speak, automatically on one side or the other of a contradiction? Indeed, according to some definitions of "belief," there would be cases in which it was illogical to regard believing as "propositional" at all. Russell, for example, has defined "belief" as denoting "a state of mind or body or both in which an animal acts with reference to something not sensibly present." Explaining further, he says: "When I go to the station in expectation of finding a train, my action expresses belief. So does the action of a dog excited by the smell of a fox" (1948: 129). Assuming the excitement of the dog to be as nonpropositional as any unconscious gesture on the part of the sceptic, why should the sceptic's unconscious actions be considered as tantamount to "propositional" beliefs when the dog's patently should not? Would it not be as incorrect to charge the sceptic with inconsistency here as it would to accuse the dog of dogmatism?

Such broad definitions of belief, however, may raise objections. We might prefer to say that belief is always propositional and that the confident behavior of beings incapable of formulating propositions should never be described as believing. A man can believe, but a dog cannot; moreover, even if a man always, to some extent, behaves confidently without prior formulation of and taking a stand on propositions, he is able, as the dog is not, to draw the correct consequences from his own behavior and to see that it does, if not necessarily amount to belief, at least compel acceptance of certain beliefs once the relevant propositions have been formulated. Thus, on entering a room, a man can reflect on the fact that the floor supports him, and though perhaps still denying that his confident entry into the room amounted in itself to believing anything, he may find himself forced to conclude that the proposition that the floor can support him is true. But why stop here? If the events in one's life compel acceptance of successions of propositions, must not one's unquestioning reliance on innumerable everyday details be itself explained by this continual canceling of licences to hold options on pairs of contradictory statements? Surely, our unconscious confidence and trust are a kind of summing up of our successes and based on acceptance of

certain general propositions (for example, the proposition that everyday details can mostly be relied on, or that only in exceptional and usually easily identifiable cases floors are not to be relied on).

If there were no sense in which the sceptic could acknowledge the reliability of things, either to himself or to others, it would indeed be hard to defend him. If he must always find it inappropriate to say things like "It held!", "Of course I didn't think it might give way," then we should want to know why he continued to behave as if he did find things reliable. If his silence is to be more than "official," we should probably regard it as pathological, as a fear of *saying* anything, rather than an expression of anything approximating a genuine sceptical attitude.

However, if Sextus is right, the Pyrrhonist is not at all barred from acknowledging the appearances, either to himself or to others; he, like everyone else, may utter expressions appropriate to the appearances when the situation calls for him to do so. Sextus, we recall, distinguishes between affirming the truth of what one says and merely acquiescing in the appearances. By making provision for the possibility of a kind of verbal assent to appearances, Sextus would allow that the sceptic may convey in words what *appears* to him, but in a way that does not amount to an assertion in the sense in which to assert something is positively to take a stand on one side or the other of a contradiction (cf. p. 8). Thus, if something feels cold to me and I say "It feels cold," I may be doing no more than publicizing the appearance; ideally my words are then simple effects of my states of perception, unprocessed by interpretation and conceptualization (including any conceptualization to the effect that this is all they are). I may say "It seems cold" and yet with perfect consistency neither affirm nor deny the *proposition* "It seems cold." Similarly, with utterances like "I wouldn't walk on the floor unless I thought it would hold me," it may be quite consistent to regard these utterances as appropriate to the occasion and yet deny that the act of walking on the floor either implied or compelled acceptance of the proposition that the floor was able to support one's weight.

A sceptic, according to the kind of distinction Sextus indicates, may acquiesce, at the time or retrospectively, in his normal and unimpeded entry into the room; he might even publicize it in the form of a running commentary, saying things like "Now I'm walking over the floor, a few creaks, but everything seems all right. There, I've made it!" But in using these words, he is only conveying his impression of what happens; he is no more

stating that a series of propositions are true than, when he recalls the events later on, he is entertaining propositions to the effect *that* such events occurred. If the context should call for the latter, he might refuse to be drawn to say that as for taking a stand in favor of some proposition to the exclusion of its negation, he feels that in the nature of this special kind of case he would rather not commit himself. To assert that something is true is one thing; to give one's impression is quite another. In the former case, one makes use of clear-cut distinctions and concepts, some of which (as will appear in chapter 4) are awkward, even impossible, to put into practice at all; while the latter case is no more than, as it were, letting the events speak for themselves—a case in which the speaker functions “angelically,” as no more than a messenger of the appearances.

The substance of the sympathetic metasceptic's case can be summed up as follows. Confident behavior, including verbal behavior, is one kind of event among others. But just as verbal expressions of confidence are not necessarily expressions of statements to the effect that one is confident, so confident action in the world is not implicitly a matter of affirming that something is the case. Consequently, in refraining from taking a stand retrospectively on his own confident behavior and successes, the sceptic is not prevented from giving retrospective expression to his confidence. Retrospective expressions of confidence are no different from any other expressions of confidence; there is as little basis in them as in the sceptic's confident actions to support the allegation that he is not a sceptic. His confidence neither implies nor compels in him a commitment to the truth or falsity of propositions.

The strength of the metasceptic's case is suggested by the very difference between acting from impulse and habit, on the one hand, and both formulating propositions and accepting or rejecting them, on the other. They are different activities, if not altogether, at least in degree of complexity and extent of commitment. Moreover, it is impossible to infer one's commitment to the truth or falsity of propositions from observation of one's own behavior, even verbal behavior. How would we even go about the task of identifying the supposed propositions on the strength of the behavior, or locate the concepts in terms of which they are formulated? If it is said that you cannot act without a world in which to act, and that therefore any action on one's part involves the assumption that there is a world, it need only be pointed out that not even on their occurrence on this page do the words “There is a

world” determine a proposition. There is nothing in these words to suggest the specific rules of definition and the conceptualizations that the sentence they comprise may be used to convey on any particular occasion. As elements in a particular person’s behavior, they are as open to interpretation as any other piece of behavior, and as in the case of nonverbal behavior, they may not be intended to convey anything “propositional” at all.

We shall not add more here in support of the metasceptic’s case. Later, in chapter 4, we shall have more to say about the complications involved in asserting truth and falsity. But at least it should be apparent that confident action does not, in any straightforward sense, either involve or compel propositional commitment. If, as Sextus, Hume, James, Russell, and others suggest, nature can make us believe things in the absence of what the intellect would consider good reason for belief in their truth or probability, then there would seem to be some initial plausibility in the view that there is no more than a likelihood on any particular occasion that natural confidence and trust in this or that respect implies a disposition to assert the truth of any corresponding propositions.

Can the Sceptic Believe?

If it is possible to believe a proposition in the absence of intellectually adequate reasons for belief in its truth or probability, is it not also possible to believe it without committing oneself to belief in its truth or probability?

The answer to this question is complicated by a variability in the use of the term *belief*. Sometimes to believe means to accept that something is certain: sometimes it means that *one* is certain although the *something* may not be; other times it means that one is not certain, since one does not *know*, but is only inclined to be certain. As we saw in Russell’s definition, belief can even be used to cover behavior that involves no verbalizable envisaging of states of affairs at all, but simply an attitude of unquestioning expectation. James (1957: 89) says that “there is some believing tendency wherever there is willingness to act. . . .” And he accepts that there is a sense in which “we find ourselves believing, we hardly know how or why” (ibid., p. 93), as if we could come across our own beliefs by observing our own behavior.

But, then, could not the sceptic also believe what he and others, by noting his actions and words, find him to be believing? Certainly, the definition of the sceptic—as one who fails to find arguments for or against a

proposition sufficiently strong to warrant a decision—seems to allow him considerable room for maneuvering. And the question of whether or not he can believe may only turn on what one chooses to mean by “belief.” It is clear, for example, that if to believe something he must accept unreservedly some proposition as true or probable, the sceptic cannot believe. If, on the other hand, beliefs are understood more broadly in terms of behavior that may in principle be dissociated from commitment to the truth or probability of propositions, the sceptic can be a believer. In that case, the limits to scepticism may be thought to come when the sceptic’s behavior lends itself more properly to the terminology of *conviction* rather than *belief*—in that to be convinced about something suggests a kind of deliberate decision or at least a decisiveness that is quite alien to suspension of judgment. However, even this may give the sceptic less latitude than he is due. Is it possible, for example, to consider an occasion in which we could aptly describe participants in a program of action as having strong convictions about the best way to proceed, and as feeling quite sure that a fair number of envisaged events may be relied on to occur, and yet deny that they were thereby committed to accepting propositions? At least it could be psychologically incorrect to assume that, if asked, they would seriously maintain that they know what is best, that what they say about the future, for example the weather, is true. But on what basis, then, could it be claimed that their actions expose their commitments? Thus we seem to reach a point at which, far from any action at all on the part of the sceptic betraying his innate dogmatism, the problem is rather to find any kind of action that could be considered adequate evidence of the kind of commitment that the sceptic, according to Sextus’s definition, avoids.

James, we may recall, says that “since belief is measured by action, he who forbids us to believe religion to be true, necessarily also forbids us to act as we should if we did believe it to be true.” But whether we conclude that here is one kind of activity from which the sceptic is debarred depends on the part we ascribe to commitment in religious belief. James (1957: 182) himself argues “in defence of our right to adopt a believing attitude in religious matters, in spite of the fact that our merely logical intellect may not have been coerced.” The abstention from religious belief in the absence of sufficient intellectual justification is regarded by James as itself an act of will, inspired by the fear of making mistakes. In enjoining us to believe truth rather than shun error in regard to religion, James presupposes that

religious belief “requires, or inspires” certain actions that we would be debarred from if we abstained from such belief. “The religious hypothesis gives to the world an expression which specifically determines our reactions, and makes them in a large part unlike what they might be on a purely naturalistic scheme of beliefs” (ibid., p. 108 fn.).

It is not clear, however, that the sceptic’s world cannot be colored by religious beliefs, and that his reactions cannot be determined by them. The crucial question here concerns the part played in these reactions and in the expression that determines them by belief in the truth or probability of religious propositions. We might stretch matters even further and say it concerns the part played in believing in the truth or probability of propositions by *commitment* to their truth or probability.

It is true that in some cases membership of a religious community may depend on acceptance of this special kind. On the other hand, it is hard to see what specific reactions membership in this sense could determine; and in any case, communities like these would be just the ones we should expect the sceptic to avoid. Usually, as in the case of political and social ideologies, little pressure is exerted on people actually to affirm the factual truth of whatever religious propositions they subscribe to; it is enough to exhibit an appropriate positive attitude. If there is anything at all that the sceptic would seem to be unable to derive from religion, it would be a settled conviction, say, in a personal universe. But even if such conviction plays an important part in religion, it is hardly essential. Conviction and faith, after all, are not the same, and in stressing the difference, believers are often insisting on the sufficiency of the latter.

Our defense of the sceptic may tend to be misconstrued at this point. We may seem to be on the verge of picturing him as being able to participate in the beliefs of his nonsceptical fellow citizens because his reservations about them concern merely the philosophical status of the evidence available for these beliefs. This kind of defense has often been made on behalf of the sceptic. Popkin (1967), for example, says that

[T]he historical skeptics . . . distinguished believing various matters from having sufficient reasons for believing them. Regardless of the legends about Pyrrho, the skeptical authors seem to have followed Huet’s view that it is one thing to philosophize and another to live, and that many propositions may be philosophically dubious but acceptable or even indubitable as living options.

(Popkin 1967: 460)

The reservations of the sceptic thus appear as nothing more than an intellectual appendix attached to everyday beliefs, according to which it is stated that the beliefs in question are philosophically dubious.

However, as we have already pointed out, the Pyrrhonist cannot have *philosophical* reservations, meaning he is in no position to judge whether or not the evidence for believing a proposition is philosophically adequate. As we have stressed, the Pyrrhonist can have no judgment of the inadequacy of evidence other than his own reluctance to abandon the search for counterarguments. This reluctance represents a personal, not a philosophical, reticence to be convinced.

James (1957: 89) defines a living option as one in which both hypotheses make some appeal to one's belief, the extent of this appeal being measured by one's willingness to act. But he distinguishes between the livingness and the genuineness of an option. Although "Choose between going out with your umbrella or without it" may be a living option in his sense, it is not a genuine one, because it is not forced; one can avoid going out at all.⁵ According to our account, the sceptic is a person who finds that no options are genuine in this sense. For, as we have indicated, the sceptic's experience does not formulate itself into propositions, nor are the circumstances in which his ordinary everyday expectations are fulfilled or disappointed sufficient in themselves to compel him to take a stand. It is not, as Popkin suggests, that the sceptic relies on a theoretical distinction that makes his reservations about everyday propositions merely formal, but rather that propositions of all kinds involve conceptualizations of experience and that their acceptance or rejection requires acquiescence in much more than the mere course of events in one's experience.

Russell (1945) has an alternative picture of the sceptic acting out a common life with his nonsceptical fellows. He states that "a modern disciple [of Pyrrho] would go to church on Sundays and perform the correct genuflections, but without any of the religious beliefs that are supposed to inspire these actions" (ibid., p. 233). But this ignores the subtle variations of attitude that the term *belief* tends to obscure. The sceptic's trust in his own impulses and in the traditions of his environment need not express itself in a mere formal allegiance to the beliefs that his nonsceptical fellow citizens attach to their actions. The sceptic is not one who, lacking the motivating power of any beliefs of his own, must, if he is to move at all, hitch himself to the habits of his society. If he genuflects on Sundays, this may be

due simply to his having been brought up in a religious household and to his having not, as yet, found a compelling reason to stifle the impulses that are bequeathed to him as a result of others' acceptance of these religious propositions. He may still have the appropriate dispositions; being a sceptic, he will simply be one who has failed to come to any final decision about the truth of the beliefs from which his actions spring.

Equally likely, however, the genuflecting sceptic may be a particularly venturesome sceptic who is willing to test the power of religious attitudes to overwhelm his scepticism. He may even go so far as to acknowledge their power, but still not succumb to them to the extent of excluding the possibility of the relevant religious propositions being false. Here there might seem to be little to distinguish the sceptic from the mature religious believer who strives to sustain his religious attitude on something less than absolute conviction. To the religious minds of Kierkegaard and others, of course, the confusion of knowledge with faith is directly irreligious. On the other hand, one would expect important differences in the attitudes of the religious believer and the experimenting sceptic. The faith of the believer in the truth of religious propositions is something that the sceptic can only pretend to himself that he has; if he really had it, he would not be a sceptic. A sceptic's participation in the propositional aspects of religious belief cannot therefore be genuinely religious. But this does not mean that he cannot act and react as he would if he genuinely believed in the truth of the propositions. Moreover, it is debatable how much of the characteristically religious "expression" that James refers to is dependent on a genuine acceptance of the "religious hypothesis."

The difference between impulses and judgment is reflected in our interpersonal relationships. We trust others, some implicitly, others up to a point. To the extent that we trust these individuals, we may be disposed to make assertions about them that claim truth or probability. But I think that nearly everyone has had occasion to feel that this trust or mistrust, even if put into words, does not correspond to a definite opinion, or to any claim to objective validity that we might be called on to make in certain circumstances. Here, too, the sceptic may preserve his naive attitudes of trust and mistrust, his confidence and diffidence, and the feelings of certainty and uncertainty that he has for others. His world remains, in this respect, the same as that of the nonsceptic. The only difference is that for him the act of asserting the truth or falsity of a proposition is part of a special occasion in

which something quite different is expected of him. Rather than make judgments, he would tend, as Sextus indicates, to cultivate perceptual and emotional sensitivity, and as this sensitivity increased so would the need for claims of objective truth vanish, or be substantially reduced.

Must the Sceptic Be a Doubter?

There are no grounds in Sextus's description for picturing the mature sceptic as a person who shows indetermination, irresoluteness, indecision, wavering, hesitation, suspense, perplexity, bewilderment, embarrassment, confusion, puzzlement, disbelief, incredulity, mistrust, diffidence, or suspicion, however fittingly these terms may describe his state of mind as he listens to dogmatists. But Sextus does list four names of the adherents of his philosophy—the sceptics, the zetetics, the doubters, and the Pyrrhonists. It might seem that the first two, deriving from Greek terms for looking about in a searching manner, and particularly the third one alluding to doubt, suggest characteristics not at all conducive to a profound peace of mind. However, it is clear that Sextus introduces them simply in order to classify abstract philosophies according to how they stand in a particular discussion, namely on the true knowledge of reality. They need not designate personal traits.

There is nothing here to suggest that the sceptic, as an actual person, should feel obliged to go around doubting or seeking any more than others. Indeed, the urge to doubt and seek should apply more to the dogmatist for, as we have suggested, the more one postulates as true, and the more entangled one gets in the intellectualization of attitudes, the more there is to doubt. By refraining from dogmatizing, one may reduce the occasions for doubt. In any case, the discussion in the two previous sections should have effectively undermined the assumption that the sceptic must be in a perpetual state of doubt and indecision. The sceptic's reservations are simply not of the kind that are directly reflected in his reaction to his surroundings. Insofar as they do affect his attitudes and behavior, these reservations are expressed not in any preoccupation with doubt, but in an avoidance of just those dogmatic forms of confidence that tend to give rise to doubt and mental tension.

The difference between the doubter and the sceptic in Sextus's sense can be illustrated by two kinds of dialogues:

The Doubter

The dogmatist: P is true.
The doubter: I doubt it; there is the following source of error . . .
The dogmatist: You mean not- p is true?
The doubter: I doubt whether not- p is true; there is the following source of error . . .

The Sceptic

The dogmatist: P is true.
The sceptic: Why should I accept p rather than not- p as true?
The dogmatist: Because argument A proves p .
The sceptic: Why should I accept " A proves p " as true rather than " B proves not- p "?

Where the doubter is continually disappointed with the candidate convictions that offer themselves for acceptance, the sceptic, resting ("until further notice") in his *epoché*, has no pressing vacancies for them. During his dialogue with the dogmatist, there need be no inkling of doubt in his mind.

Is the Sceptic Unperturbed by Modern Science?

It has been suggested that although scepticism may have been psychologically possible in the Hellenic world, this is only because science at that time played no important role in daily life. Today, however, with scientific knowledge pervading society at all levels and scientific regularities forming the background of our lives every moment of the day, scepticism can no longer be regarded as psychologically possible.

Although there is much to be said for this point, technical development has also introduced considerable complexity, irregularity, and unpredictability. And, of course, even in the time of Sextus, people relied on the regularities of the seasons, the moon, and the uses of words. Furthermore, even if the beneficiary of modern science has a thousand regularities at his beck and call, unquestioning reliance often invites a rude awakening.

In any case, those who are impressed by scientific methodology will find that truth, as a property of scientific results, has been reinterpreted. This is due to intensive indoctrination with a methodology of science that stresses the uncertainty of scientific knowledge, the commitment to hold any question open, and the idea that the main function of scientific propositions is

as working hypotheses. Since the dominating philosophies at the time of Sextus—Stoicism, varieties of Platonism, and Epicureanism—were all dogmatic, and the religions of the day claimed to contain true knowledge, our own environment of scientific education and creativity can hardly be considered more hostile to Pyrrhonian scepticism than the environment of Sextus. In the philosophy of the formal sciences, too, an influential movement stresses postulates, conventions, rules at the base of mathematics, rather than truth and objective validity. The violations are thus conceived as forms of bad, unsocial, or incorrect behavior.

Uncertainty in natural science does not exclude probability. There are, however, influential movements in philosophy that deny the probability of scientific knowledge. One of them is closely connected with the Catholic Church, representing a variant of Neothomism. Pierre Duhem is an outstanding representative. Another is represented by Karl R. Popper, a great disbeliever in the capacity of induction to justify scientific propositions and of probability as a property given to scientific propositions by their particular confirming instances.

In short, methodology of the sciences, formal and nonformal, is compatible with the view that anything can happen at any time; it is unscientific to say that some happenings are *objectively* more probable than others. Our life of action, even in a society pervaded by presuppositions of scientific regularity, is not, of course, dependent on the correctness of any definite proposition about a regularity. It is enough that we find ourselves trusting that the future will resemble the past or, to be more exact, that we act in a trusting way that may best be suggested by such exclamations as "Surely the future will resemble the past!" or "You can always rely on the force of gravity!"

So, while many drop from the ranks of potential sceptics because of an unshakable belief in the truth or objective probabilities of scientific knowledge, others are led to scepticism by their very studies of the special character of scientific knowledge.

Is the Sceptic Sensitive to the Difference Between Real and Apparent?

It has also been suggested that by confining himself to reports of his own beliefs and thoughts, the sceptic collapses the distinction between appearance and reality and thus denies himself the use of the category of the real.

The sceptic, however, does not reject the everyday distinction between what seems to him now to be the case and what really is the case. That is, he may retain a kind of image of the distinction between reality and mere appearance without putting a specific interpretation on it. At least this is how we may understand some of his reactions and utterances. He, like anyone else, can be misled by illusions, note his mistakes, and correct them. He simply suspends judgment in relation to any proposition claiming to say something *true* about how things really are.

To understand the sceptic's mind, we must appreciate that reality, in this respect, is utterly in the dark, always eluding him, never grasped in knowledge. But it would be incorrect to picture him as feeling that reality is utterly unintelligible, incomprehensible, and unreachable. (That would be the feeling of the Academicians, not of the sceptics, according to Sextus.) Reality is in darkness, but not *necessarily* in darkness. It might be brought to light. The sceptic, at least, is not convinced that it cannot. In fact, the sceptic himself may, in his own opinion, be the one to bring it to light; he may discover how things really are—in at least one respect. This, of course, would mean the end of his career as a sceptic. But, as was pointed out in chapter 1, it would be wrong to view the sceptic as serving a self-imposed life sentence, or to view him as a person who could not envisage a possible defection to dogmatism.

Tentatively, I conclude that the sceptic contemplating questions such as "How is reality?" and "What is real?" is likely to feel that reality is enigmatic, ambiguous, strange, obscure, veiled, unpredictable, and unmanageable. Compared with the dogmatist, who thinks he knows a large number of important truths and has full access to a reality that is quite intelligible in most respects, the sceptic is likely to feel more or less powerless. Anything may happen at any moment; there is no certain way of stopping any process.

It seems that if a sceptic has a penchant for contemplating reality and for wondering about how things really are, he must become depressed, or at least awed. I suppose one must acknowledge a need in men for unveiling, controlling, and predicting what is real. On the other hand, of course, there are secondary needs of an opposite kind: needs for a universe that is too great and complex to be understood, a reality that possibly has layers we cannot penetrate, with mysterious depths and unfathomable riddles.

So, even if the sceptic is likely to, or will as a rule, feel reality to be enigmatic, ambiguous, and so on, there are, psychologically, different frame-

THE PSYCHOLOGICAL POSSIBILITY OF SCEPTICISM

works in which to put these feelings. The resultant complex attitude may quite well not be a negative one of perplexity, fear, and embarrassment.

So much for the likely feelings of the sceptic toward reality as opposed to mere appearance, insofar as the distinction is something he acknowledges. One must, however, keep in mind that the fundamental distinction for the sceptic is not that between real and apparent, but between known to be true (or valid) and not known to be true (or valid). The sceptic may ask himself, Do I really want this gadget? or Do I really trust this friend? An answer may be found through listening to his own impulses and inclinations or through discriminating between levels or depths of motivation. The sceptic might also say "The boss looked angry, but he was not *really* angry" without claiming truth, but only by way of conveying his impressions. For there are impressions both of real anger and of apparent anger. Thus, in matters of interpersonal relations, the sceptic may, more often than even the dogmatist, consciously discriminate between real and apparent. But he does so without touching epistemological distinctions or the professional philosophical debate on reality and appearance.

General Outlooks Generate Scepticism

The sceptics described by Sextus came to doubt and then suspend judgment through their encounters with dogmatic disagreement and controversy. It may be that today, however, the most likely development of a complete sceptic (surrounded by a dogmatic environment) includes a presceptical stage at which the later sceptic has an intellectually well-organized, unified outlook on life and the cosmos.

From experiments in social and physical perception we know that value judgments clearly and significantly influence perception. One may remind oneself, for instance, of how coins worth more look bigger. A unified outlook influences all regions of perception. Or, to be more exact, there will be an interaction between different factors and layers of the mind with a resulting personality structure characteristic of the outlook. The intellectual organization of an outlook inevitably results in a distinction between basic and less basic parts. The mass of judgments of value and of fact will be felt to rest on certain fundamentals, certain basic assumptions, or intuitive insights.

Can We Assume That Sextus and His Less Articulate Friends Fulfill the Requirements?

Having reached this stage, the individual is constantly in a danger zone. If the personality is not highly integrated but permits the individual with a certain degree of calmness, detachment, or alienation to inspect his own outlook as such, a major kind of catastrophe or crisis may occur. If, for some motive and reason, inspection is carried out with a touch of basic doubt or feeling of strangeness, the individual comes to look on his own outlook in its very basic features as something profoundly subjective, as the truthful expression of one individual basic way of seeing and feeling things, but without any consequences for any other human being. That is, the holder of an intellectually well-organized, unified outlook creates some of the necessary conditions for a thoroughgoing scepticism. He has the breadth and intensity of vision lacking among people who are only intermittently and tentatively engaged in working out their own outlook on life and the cosmos.

From a philosophic, or let us say epistemological, point of view, fundamental principles must have self-evidence, an internal or immanent obviousness. Being fundamental, they are by definition impossible to defend by anything external to themselves; they express a last stand. If, therefore, an individual comes into an ambiguous relationship to the only foundations he can identify himself with, the whole edifice that rests on the foundations becomes suspect. He doubts its truth and validity, yet there is no objective test available. If his further development goes well, he will acquire the status of a mature sceptic, enjoying peace of mind. But he may not develop in this way—he may instead develop negativism, cynicism, nihilism, and despair.

Can We Assume That Sextus and His Less Articulate Friends Fulfill the Requirements?

We have, in deference to Sextus, defined scepticism genetically, in terms of a characteristic personal development. Those and only those persons who show this development are (by definition) sceptics.

The possibility of becoming a sceptic is then identical with the possibility of undergoing this development. And the possibility of remaining a sceptic is equal to the possibility of continuing to show the characteristics attributed by Sextus to the mature sceptic. Sextus says nothing about persons who do not remain mature sceptics, the “renegades” or “backsliders.” These would

be sceptics who eventually lose their suspension of judgment in favor of certain propositions—let us say those of Heraclitus or Protagoras.

Although we are not concerned with the question of for how long it is possible or practicable to remain a sceptic, in discussing the psychological possibility of scepticism we nevertheless think of time intervals of some length. A person may scarcely be said to be a Catholic or a conservative or a pessimist for five minutes—that would be too short. On the other hand, a stability lasting twenty years or more is not required in order to qualify. The same considerations apply to scepticism. There is no built-in requirement of lifelong adherence, but there is, of course, a requirement of stability and profound attachment.

Sextus talks about sceptics as if they were persons existing at and before his time. Very often he uses phrases suggesting that he himself is a sceptic. One must nevertheless pose the questions: Was Sextus, or were his friends, *really* sceptics at least during some part of their lives? Were at least some persons *correctly* subsumable under the concept of sceptic as defined genetically? Or does Sextus only describe ideal sceptics, fictitious personalities?

There is nothing in the writings of Sextus or in other Greek works (for example, those of Diogenes Laertius) that directly suggests the fictitiousness of his sceptics. In the literature of his day and earlier, the existence of sceptical “schools” and sceptical philosophers is taken for granted. More exactly, the term *sceptical* and its cognates are used to qualify adherents of certain schools and of single personalities.⁶

From a psychological and social point of view, our ultimate decision will mainly build on our assumption as to what is possible *today*. We can try to envisage what might be the difference between human life here and now and life in the Hellenic world, but ultimately the question of the psychological and social possibility of scepticism has to be attacked from our knowledge of the human beings of today.

Concluding tentatively, we shall form five hypotheses:

1. *Scepticism is psychologically possible.* It is possible in its full development as pictured by Sextus, with the additional features described below.
2. *Approximation to scepticism is psychologically a more likely and durable state.* The same holds for states in which one’s attitudes are too vague or ambiguous in outline to decide on their exact relations to sceptical requirements.

3. *People most likely to develop close approximations to scepticism are those who have a marked tendency and ability to form integrated, general attitudes, coloring their whole mental life and outlook.* Such persons will eventually also be able to suspend complex attitudes in the sense of holding them back from full, free operation. The psychological mechanisms behind truth claims and claims of objective validity may thus be suspended.
4. *Experience furnishes some material relevant to the situation of a sceptic in a nonsceptical milieu.* The conservatism and other social traits of the sceptic are understandable interactions within a dominantly non-sceptical milieu. The possibility of a sceptical “epidemic,” a flourishing scepticism gradually wiping out dogmatism, has never been discussed seriously. The main questions raised are, Would inquisitiveness, and therefore science, come to a standstill? Will children be left untaught? This latter eventuality would have disastrous effects on any civilization.
5. *As to the possibility of stable sceptical communities, there is no precedent to learn from.* In such a community, if one ever came to exist, there would be little incentive for the individual to form a general outlook, and he would not be helped to form one by learning to know existing philosophies. If—as has been supposed—one is most likely to form scepticism when doubt undermines a general outlook to which one has given all one’s mind, the main historical source of scepticism would dry up in a stable sceptical community. Thus, the community will eventually turn antisceptical, restoring the supremacy of dogmatism in some form or another.

III

Scepticism and Positive Mental Health

Introduction

The proposal that scepticism is possible in practice immediately gives rise to a further question: whether, and in what respect, scepticism is at all practically desirable. The host of issues associated with this question cannot be adequately discussed here. Before going on to discuss scepticism in the light of more or less purely epistemological considerations, we can at least pause to consider how scepticism stands with regard to an area in which the practical issues have already been formulated in comparatively precise terms, and the normative issues, as criteria for mental health, have been agreed on more or less, if only implicitly. What I propose to do here, therefore, is subject the radical sceptic to the test of currently accepted criteria of positive mental health.

A practical problem very germane to the issue of scepticism arises here in confronting the Hellenic sceptic with modern teaching on positive mental health. The exponents are many, and seeker though he is, the sceptic can hardly fail to notice with some discouragement that the specialists are not of one mind. Therefore, to protect him from an unnecessarily obvious demonstration of the availability of counterarguments, let us confront him with but one representative, Marie Jahoda. Or, to be more exact, let us confront him with the criteria listed in her book *Current Concepts of Positive Mental Health* (1958).

Confrontation with Six Criteria of Positive Mental Health

The first major category of criteria refers to the attitudes of an individual toward his own self. However, I do not think much can be said about that kind of criterion because it does not connect in an obvious way with what

Sextus is talking about. The second criterion, however, opens up an interesting question: can the sceptic be said to display a satisfactory degree of growth, development, or self-actualization? Gordon Allport explains that growth motives “maintain tension in the interest of distant and often unattainable goals” (Jahoda 1958: 33).¹ By growth motives he refers to “the hold that ideals gain upon the process of development” (ibid.). Now, perhaps it is only possible for unattainable or very distant goals to furnish strong motivation if the individual is convinced that certain propositions are unquestionably true and certain goods absolutely or objectively good. Regarding distant goals in general, verbalization plays a decisive role, but I think one must concede that belief in a definite truth is hardly a necessary requirement of one’s being said to have a distant goal. Gardeners may plant trees for the joy of their grandchildren but without making definite predictions. The sceptic may make evaluations concerning distant matters that he envisages, and the verbalizations may be part of what stimulates him to act consistently through long periods, but he need not use any of these verbalizations to express knowledge. I tentatively conclude that scepticism is not a decisive obstacle to self-actualization. On the positive side, the sceptic has at least one distant goal—to find truth—and one ideal: true knowledge. As metasceptics, we shall attribute this to him even if he always suspends judgment when we discuss this point with him.

Abraham H. Maslow, stressing self-actualization as a criterion of mental health, finds that it is accompanied by a “genuine desire to help the human race” (Jahoda 1958: 34). Strong and persistent motivation in helping our race in complete generality—or somewhat less ambitiously, in helping the developing countries or any considerable portion of mankind (without hating the rest)—may well require a heavy reliance on abstract thinking and conclusions derived from such thinking. The sceptic, not being able to concede the truth of even quite simple propositions, may not be able to visualize the problem of helping the human race in its totality. If he meets a hungry child, he meets *that* child, not the fifty million hungry children of the same nationality. He would tend to answer Maslow, “Yes, I think I see the terrible importance of what you are saying, but only in moments in which I succeed in believing in the truth of a long list of propositions. However, I see no grounds for accepting them rather than their negations as true.” Any political, social, or ethical creed based on a substructure of articulated unquestioned truths would be without appeal to the mature sceptic. In conclu-

sion, then, we may suggest that the sceptic would receive a low score if positive mental health were judged by desire to help the human race at large. A good lecturer on the subject of helping mankind, however, will illustrate his points by pictures of starving children or desperate mothers. The sceptic might be motivated to help, immediately and vigorously, on seeing the pictures and listening to the case studies, whereas the ordinary listener would curb his feelings for political, financial, and other reasons that are highly dependent on belief in general truths. In short, the sceptic may well be more fitted to offer spontaneous and wholehearted help. But if Maslow insists that he must have a strong desire to help *mankind* in order to satisfy the criterion, the sceptic will fail.

As a third category of criteria, Jahoda mentions integration. At this point, too, Allport seems to be the psychologist who makes the sceptic appear most unhealthy. He speaks about a unifying philosophy of life as a sign of maturity. And although the metasceptic and diligent observer of the sceptic has ample reasons to accord a unifying philosophy to the sceptic, this does not seem to be enough for Allport. The mature person “participates and reflects, lives and laughs, according to some embracing philosophy of life developed to his own satisfaction and representing to himself his place in the scheme of things” (ibid., p. 39).

If we think of a philosophy of life as an outlook on life in general, and if it is to be developed in contrast to other philosophies of life, the sceptic has no philosophy of life. He has no *doctrinal* philosophy of life, being antisceptically free of belief in particular philosophical systematizations. Therefore, he cannot place himself as an outsider looking at himself and his place in the general scheme of things. He does not believe that he knows of any objective scheme of things. So, Allport must conclude, it seems that the sceptic dismally fails, and that he is utterly unhealthy, according to at least one integration criterion.

But there are grounds for the opposite conclusion. About other people we may say they have a definite outlook about life, even life in complete intercultural generality, without their saying anything about it either to themselves or to us. We speak about the old peasant’s outlook in spite of the fact that one of the old peasant’s traits is extreme muteness. He may even protest, swearing that he would never dream of considering life in general or subject his whole personal life to reflection. Allport might agree to this. A unifying nonprofessional philosophy of life may not be articulated in any form.

If this is granted, however, the sceptic may rise to a pinnacle of healthiness insofar as he has a way of taking things that is both peculiar and unified.

Our conclusion regarding integration will therefore follow a middle course. One may speak of the sceptic's outlook, and the sceptical way marks an important unifying ingredient. Yet in spite of this, he may in many ways show considerable looseness or even disconnectedness. He will conform only roughly to the traditions of his society, according to Sextus. He will perhaps be weak in following principles and norms under stress, not holding them in any absolute manner. He will go along with others, but not all the way when this requires, as it sometimes will, a solid conviction that this or that *is* true. It is tempting to think of times of crisis when some, but not all, friends or fellow citizens stand up to very severe tests. The sceptic's resistance to stress may show weak spots, but not in any glaring fashion. He never makes great claims, his level of aspiration is moderate, and he does not jump up as a lion to fall down as a mouse. These reflections follow closely what Sextus himself says about the social relations of the sceptic. If we allow ourselves to depart from his narrative in secondary matters, a different picture may emerge. Thus, today, we would concede that absence of belief in truth may well combine with strong convictions.

As a fourth major category of criteria, Jahoda lists autonomy, the individual's degree of independence from social influences. Maslow speaks about people who maintain "a relative serenity and happiness in the midst of circumstances that would drive other people to suicide" (Jahoda 1958: 47). David Riesman, also in Jahoda (*ibid.*, pp. 47–48), distinguishes between adjustment to society of the tradition-directed, inner-directed, and other-directed kinds and judges autonomy of the individual with reference to these factors. This is highly relevant for scepticism and justifies a brief digression.

It has often been noted that men of letters with sceptical inclinations tend to support the traditions of their society and are, as a matter of course, never seduced by programs of radical reform. They are conservative. It is the radical who accepts general propositions predicting the future.

Hume, considered the most consistent philosophical sceptic since antiquity, was conservative as a matter of course. But what about his autonomy? Hume's autonomy in relation to the society he supported showed itself in many ways. An example of a rather touching kind is to be found in his relation to Jean Jacques Rousseau. An individual belonging to quite a different society—a society of opposite character in part—Rousseau was,

moreover, a person of diametrically opposite character and tastes. Hume nevertheless felt himself capable of sincere friendship with Rousseau to the extent of inviting him to live in England with him. The story presents a convincing picture of a sceptic living at peace with his own society, but without self-surrender.

How would a sceptic behave under a tyrant, subjected to a terror regime? In our time this is a question that will inevitably be raised. Will he not be among the passive, at best? Will he be among those who are unable to fight for a principle, who let themselves be made instruments of criminal deeds?

In *Against the Ethicists* (trans. Bury 1936: 160–67), a fundamental attack on the Wise Man of Greek philosophical traditions, Sextus answers dogmatists who think that a sceptic will either meekly surrender to a tyrant or stand up against him, but then only inconsistently on the basis of a conviction about what is good or evil, or desirable and undesirable, and thus inconsistently. A sceptic must either act dishonorably or be inconsistent. Sextus questions the dogmatic assumption that the capability of desiring some things and avoiding others presumes a doctrine of some kind, a belief in knowing this or that to be the case. Life can be lived without that. If the tyrant tries to compel a sceptic to do a forbidden act, he will refuse on the basis of laws and customs. Today we will perhaps add “and according to conscience” (whether in agreement or in disagreement with the laws and customs of the time and place). Sextus adds that the sceptic will endure hardships more easily because of his lack of beliefs *about* suffering—beliefs that cause additional suffering.

The inadequacy of individual perception is clearly manifested in many neuroses, “the neurotic is not only emotionally sick—he is cognitively *wrong*”—to quote Maslow again (Jahoda 1958: 50). As a fifth proposed category of criteria, this point must be considered for a moment. The sceptic does not deny the distinction between correct and incorrect perception, it is just that he does not find in practice any indisputable criterion of correctness. In this he does not seem to feel very different from Jahoda, who exclaims (*ibid.*): “Particularly when the object of perception is social in nature—but even when it is physical stimuli—who is to say what is ‘correct’?” Further, she intimates that correctness carries the implication that reality is static and limited and that there is only one way of looking at it.

In the face of this unexpected and remarkable support for the healthiness of a sceptical outlook, I find it justifiable to proceed to the last crite-

tion, environmental mastery. There is one proposal here that directly affects the sceptic, that of making the capacity to *solve* problems a criterion. The sceptic admits that as a person he is incapable of finding the solution of any problem whatsoever in terms of true and false. He would fail dismally as a respondent to the innumerable true/false questionnaires of our cognitively atomistic and optimistic age. Jahoda comes to his aid here too, however, suggesting that it is the process of solving rather than the end product that discloses the healthy mind. Success in solving cannot count for such. The process or method itself does not imply any assertion with a truth-claim attached, and I think nothing can be said in general here against the sceptic.

Sextus himself was very probably a physician, one of the long line of Hellenic physicians systematically opposed to all philosophizing in medicine. The so-called empirical school tried to keep as close as possible to empirical methods, suspicious of any generalization or deduction and of any attempt to find causes. As a sceptic, the medical problem-solver would also have to be critical of conceptualizing the relation between patient and doctor, favoring direct interaction at the nonconceptual level.

Our general conclusion from this confrontation of the sceptical philosopher with criteria of positive mental health must, I think, be very tentative, but at the same time positive. It is that there is no good a priori or general reason to suppose that a sceptic cannot stand up to contemporary criteria of positive health.

The sceptic's failure may seem to come more easily from social rather than psychological sources: in a society that puts heavy stress on verbal conformity in the form of unconditional, explicit acceptance of ideological items in terms of true or false, the sceptic is likely to suffer maladjustment and consequent loss of peace of mind. Still, we have learned in our time how people under totalitarian pressure are capable of combining a high degree of external conformity with deep inner reservations. The sceptic may resort, as do many others, to such a form of "double-think."

The Alleged Scepticism of St. Augustine and Others

In his story of how sceptics develop, Sextus tells us how some gifted people fail to find decisive evidence either for or against any philosophical position. Contemporary psychologists will, I imagine, be justified in pronouncing that there must be a strong propensity toward finding counterargu-

ments in order not to become convinced. There must be peculiar personality traits that explain the genesis of a sceptic. It cannot be a matter of pure intellect, or pure chance.

But what traits? If, drawing on philosophy or the history of ideas, one could provide clear information on sceptical personalities of the past,² then discussion on scepticism and mental health would be greatly simplified. But such information cannot be given.

Let me take an example of a type of literature containing reports of deep scepticism. It begins with St. Augustine (b. 354–430), who says of himself that at about the age of thirty he had developed a complete scepticism. He doubted everything and gave up looking for any single truth (in the manner of the Academicians). He was profoundly unhappy, he lived in sin, and being torn between contrary impulses, had great difficulty in acting coherently. Unhappiness and scepticism thus went together.

All this he reports in his famous *Confessions* after he had found peace in Christ, that is, after a religious conversion. Now, we know that people after a profound religious or political conversion tend to be very inaccurate in their description of their own life before that happening. There is reason to believe that St. Augustine was no exception, and in particular that he was not as sceptical as he says he was. If this is not the case, we would conclude that marked scepticism of the “Academic” (not Pyrrhonian) kind is at least sometimes empirically connected *not* with peace of mind but with a state of deep frustration, indecisiveness, and with moral confusion.

Since Augustine, a long series of Christian personalities have reported on the scepticism (that is, “scepticism” in their own terminologies) that was theirs before their ultimate conversion. Some have even retained the point of view that they *are* sceptics. But it is clear that their concept of religious belief and of revelation is such that they must be said to claim at least to know the truth of every proposition of the Bible. They accept revelation as a source of knowledge of many kinds and confine their scepticism to propositions arrived at without revelation.

I have mentioned religious conversion as one current or movement in the history of ideas only as an example to illustrate the difficulties in assessing the personality background of a sceptical bent of mind. Even if that background were elucidated, it still remains to assess whether a trait found associated with non-Pyrrhonian scepticism could also be associated with the “suspension of judgment” variety. Conclusions on the psychological

and social aspects of scepticism must therefore be taken primarily from the experience of contemporary psychologists and social scientists.

It seems quite likely that converts who have overcome their harrowing doubts tend to regard scepticism in the same light as do many psychotherapists and psychiatrists. For this group, "scepticism" is often made to cover certain defense mechanisms of the unhealthy mind. The patient meets the environment, including the benevolent doctor, with constant irony, sarcasm, and stubborn or blind doubt. He uses a sceptical phraseology to defend himself, to ward off any attempt to influence him in directions in which he does not want to be influenced. From his behavior and utterances, however, it is clear that his sceptical phraseology is not based on a deep and genuine scepticism. The patient accepts many things as true and valid, for instance, as a submissive or loyal member of a gang. Or, he has a tendency to reject many things as false.

The psychiatric patient may even show symptoms of compulsive doubt, *Zweifelsucht*. In psychiatric literature there are examples of psychotic *Zweifelsucht* in which the patient fights between belief and doubt in certain metaphysical positions.³ There is no development of confidence and trust with such patients, at least not as described by the psychiatrists. Their development, especially in this respect, differs widely from that of the Pyrrhonist.

The psychopathology of doubt, indecision, perplexity, disbelief, suspicion, and mistrust is of interest to any student of sceptical tendencies, especially the sceptical stages before religious conversions. But the pictures drawn by psychiatrists bear very little resemblance to those drawn by Sextus. The Pyrrhonist is certainly very different from the psychopathic nihilist and negativist, and also from the patients who are tortured by rapid wavering or oscillation between belief and disbelief.

The Moderate or Fragmentary Scepticism of the Unphilosophical

In spite of the description of the sceptical way in the first part of this book, it is difficult to get a firm feeling for the sceptic as a person. We are invited to keep only certain rather limited characteristics in mind, the seven points of the genesis, but at the same time we want to supplement this account in such a way that a whole person emerges. I shall therefore devote the re-

mainder of this chapter to clearing up some points regarding the sceptical bent of mind—and independently of whether the sceptic is a philosopher.

Dogmatic philosophers will, of course, confront the sceptic with specimens of knowledge that are generally considered most certain. In order to be able to meet other philosophers on their own battleground, the philosophical sceptic must therefore furnish possible counterarguments against such sentences as “I feel hot now” or “I think, therefore I am,” insofar as they are posed as assertions involving the claim that they express certain or probable knowledge.

But the unphilosophical sceptic, of at least one kind, will not bother with these sentences, taking it for granted that mostly they express something that is true, but trivial. Or else, as many nonphilosophers do, he will deny the general applicability of the term *true* to the trivial or “too obvious.” His scepticism is complete in its way if it comprises all knowledge *worth knowing*, all that he ever sincerely wished he knew. I think here of religious and moral doctrines and the unphilosophical sceptic’s opinions on his own basic relations to his nearest family and friends. If he is rudely disappointed and frustrated because of opposing opinions on such things, his genesis as a sceptic can be the same as that of the philosophical sceptic described by Sextus. And if it is seen from a psychological and social point of view, the unphilosophical brand of scepticism will be complete and meaningful in spite of its fragmentary character from a strict cognitive point of view.

Suppose the complete but unphilosophical sceptic is led into philosophy and that he concedes that we have certain knowledge of a perceptual and of a purely logical kind. This does not require him to change his psychological and social status as a sceptic. If the concessions to the dogmatists are sufficiently remote from questions in which he is seriously and personally engaged, these concessions are without deeper effect. He is now moderately and fragmentarily sceptical as a professional philosopher, but still a complete sceptic in relation to all things worth knowing.

Whereas moderate, loose, or fragmentary scepticisms are scorned by the philosopher-epistemologists, they are central to our theme: the social and psychological aspects of scepticism. If we were to consider today only the radical, neatly, and professionally worked-out brands of scepticism, we would feel rather as if we were discussing the intimate life of an extremely rare, possibly long extinct, species of bird. But now, with this philosophi-

cally moderate and fragmentary yet psychosocially total or near-total brand of scepticism in view, I shall proceed to some rather bold speculations.

Encouraging a Sceptical Bent of Mind: Can It Ever Be Right?

In cases of deep and painful doubt and oscillation between opposite views, the therapist should, it seems, represent the dogmatist rather than the sceptic. That is, he or she must help the patient toward a stable view, a valid positive conclusion, whether or not valid in the eyes of the therapist. This may also apply to young people drifting along the stream with little feeling of identity or of anything that is truly expressive of themselves. They may look like potential (Pyrrhonian) sceptics, but they are not likely to become so. They have not gone through the presceptical stage of asking, What is truth? with strength and endurance. Therefore the sceptic's peace of mind cannot be theirs.

Admitting, however, that in many cases a tendency toward scepticism should *not* be encouraged, what are the cases in which it should or at least might? Let us first consider a young man called Max. He is brought up in a highly intellectual atmosphere with stress on articulated opinions justifying attitudes and actions. It is never enough for him to say, "That's the way I feel now," "I cannot help valuing this higher than that," "I just like it," "This, not that, is my duty," and so on; there must be reasons and claims of objective truth and validity. For various reasons Max has developed a keen critical sense, *contra*-argument coming to him more naturally than *pro*-argument. And this criticalness, owing to a not too greatly developed sense of superiority, comes as easily to him in respect of his *own* tentative positions as in respect of those of others.

Without being intellectually inferior, Max is constantly in trouble because he cannot form enduring verbalized convictions and because his father and others who try to press him into certain beliefs are largely immune to counterarguments relating to their own positions. When Max has to make decisions in school, as a student, as a friend, and in relation to the other sex, he insists on making positions conscious and on justifying them intellectually. He demands that his own actions should always be based on considerations of truth, correctness, and worthwhile consequences.

Any effort to change the old trait Max has of coming to see two sides of a thing, and his tendency toward detached objectivity and valid reasoning,

is liable to fail just because this feature is so deeply engrained. And, of course, few therapists would have the audacity to interfere with it, since from many points of view such a trait is an asset. However, the case is one in which help toward a more complete scepticism is warranted. What Max lacks may be said to be the courage to oppose those who make him feel that the intellectual articulation and justification of impulses is necessary, and who have implanted in him a distrust of action or attitude formation without an accompaniment of intellectual justification in terms of truth and general validity. The sceptical outlook involves a mistrust in such justifications and a capacity to see their hollowness from the point of view of intellectual detachment and honesty. Instead of feeling that this ability to see counterarguments is shameful and expressive of inferiority, Max will be encouraged to exercise his ability and stick to his resulting intellectual indecision and suspension of judgment.

One will perhaps object that Max's cure is basically not of being led to accept and further develop his sceptical bent of mind but of being led to trust his own impulses. However, the term *scepticism* has been introduced in this text as it was by Sextus, that is, in terms of the genesis of a kind of personality. Essential in Sextus's narrative is his "impression" that indecision, or rather suspension of judgment, as to truth and falsity does not result in inactivity. Natural impulses lead to action. Upbringing, social institutions, and teachers in the arts provide a sufficient basis for adjustment, both for the passive component—the accommodation—and the active, the assimilation, in the terminology of Jean Piaget. Thus, trust in one's own impulses is an integral part of the scepticism expressed by Sextus Empiricus.

An essential kind of question for Max is, How did I come to think that in order to decide whether to go to college or not I would have to solve the question of whether an interesting or lucrative job is the best for me? Or whether there is a duty for intelligent men today to go to college in order that in 1980 the United States may have more able engineers than the Soviet Union and China put together? Max would have to train himself to have a sharp awareness of his own inclinations, develop his sensitivity, get his impulses coordinated, and use his intellectual acumen to reveal for himself the unwarranted jumps from particular, concrete personal questions to more general and abstract ones, and to distinguish innocent verbalizations ("What beautiful places some college campuses are!") from more formidable articulations in terms of truth and validity.

Let us, once more, look for personality traits correlated with a profoundly sceptical bent of mind. Let us consider a middle-aged intellectually gifted person called Adam. Adam has long had a need for a unified outlook on life of the kind that Allport takes to be a sign of health. And as far as we, his psychologist friends, are able to judge, he *had* a highly unified all-pervading outlook when he was twenty-five years old. When he had that outlook, he seemed to thrive. Then he married a headstrong girl, Mary, with a different outlook. Unhappily, there developed much friction, and Adam was gradually led to *carefully articulate his own outlook*. Articulation functioned then mainly as a defense mechanism.

Articulation presupposes a certain degree of alienation from oneself, a dangerous kind of objectivity. Adam was led to look at himself from the outside and to clarify possibilities other than his own outlook. There now developed a profound indecision and general doubt, and Adam proceeded to undergo an analysis of a somewhat orthodox Freudian kind. It was soon clear that the need for a unified outlook developed out of earlier conflicts when he was torn between his father and mother. His outlook represented a victory of the father image, but there must be something left over, something incompletely integrated in his personality. This explains why his infatuation for Mary had the serious consequence of marriage, in spite of the incongruence between the two in the matter of outlooks.

The analysis was highly successful. To put it in terms of symbols, the main result was that he saw that he no longer needed to choose between mother and father. On the contrary, he felt the arbitrariness of any choice of that kind. Transferred to the field of conscious behavior, it meant a rejection of unified outlooks, a natural disinclination to let himself fasten onto any decision in terms of outlooks on life or anything else. Confronted with believers in the truth of any religion, philosophy, or political ideology, he developed counterarguments in a natural way. Having William James as a distant relative, he often justified his renunciation of knowledge in terms of pragmatism, but he did not really believe in pragmatism. He used pragmatic patterns of argumentation because they were the most convenient way of cutting off reflections leading nowhere.

Whatever the genesis of a definite general outlook, it cannot be shed like a coat. It is therefore not surprising to hear from the psychologist friends of Adam that his social and physical perceptions still have a peculiar tone or color consistent with his former highly integrated outlook. The difference

is that he will not stand up and defend his impressions and reactions as any more valid or true than any other. He trusts his impulses, but his intellectualizations have disintegrated, leaving only the minimum necessary for adjustment to his social environment.

Today I surmise that there are many psychotherapists who are not far from scepticism in their basic attitudes, however full of certainty they may sometimes be in their speech. This makes it easier to help unburden over-intellectualized minds of unnecessary, unending reflections about truth and falsity and validity and invalidity. I should think therefore that scepticism of the radical kind we are discussing should not be wholly without practical importance for psychotherapy; here at least is one context in which it may be considered practically desirable. The relevance in wider contexts of a conclusion about the practical value of scepticism in this one field must be left to those who would consider in more detail the connection between mental health and community, and the importance of a sceptical attitude among those who would seek to influence the development of society. One might reasonably predict important social implications coming from widespread scepticism, even from the fragmentary, unphilosophical kind. It should effectively undermine closed societies with their demands for explicit adherence to certain doctrines and the systematic rejection of counterargument. And in more or less open societies, scepticism should help both in the reshuffling of political priorities and in the elimination of rigid ideological reasoning that lacks any basis in spontaneous thought and feeling.

IV

Conceptual Complementarity of Evidence and Truth Requirements

Introduction

Knowledge implies truth: what is known cannot be false. This is a matter of definition. There are other requirements, too. In the usual case, knowledge of something is not attributable to someone as knowledge unless that person has reason for his belief. But even this is not quite enough, since a true belief based on reasons might still be rejected as knowledge if the reasons were not considered adequate. That is, for a true belief to be knowledge, the reasons or grounds for holding it must satisfy certain standards. Some people convey this by saying that knowledge is a title that beliefs must earn, and that they earn it not simply by being true but by being well grounded.

In taking up these points, we shall depart from the course generally taken in discussions on scepticism. Usually the epistemologist concerned with scepticism is occupied with general questions of the form “Do our beliefs ever earn the title of knowledge?” Ayer, for example, in *The Problem of Knowledge* (1956: 76), presents the sceptic as one who alleges that our reasons for believing something can never be good enough for the belief in question to count as knowledge, the argument being that a knowledge claim involves an “illegitimate inference” from one level of facts that form the premises of our knowledge claim, to another level of facts that form the conclusion. The problem, as Ayer sees it, is that of establishing our right to make what appears to be a special sort of advance beyond our data (ibid., p. 78). In the case of our belief in the existence of the external world, for example, the sceptic is represented as maintaining “that we have no access to physical objects otherwise than through the contents of our sense-experiences, which themselves are not physical” and that since the relationship between premises and conclusion is neither an inductive nor a deductive one, the inference cannot be justified. If our beliefs about the existence of

CONCEPTUAL COMPLEMENTARITY OF EVIDENCE

physical objects can never be justified, the existence of physical objects can never be known.

Here, however, we will consider not the transition from a true belief to a justified true belief but the transition from a belief that is justified to a belief that is both justified and true. That is, we shall consider the interrelationship of the truth and evidence requirements of knowledge, a change of focus that brings to light a “problem of knowledge” rather different from that normally discussed, a problem of adequately conceptualizing expressions of the form “I know that p ” in terms of truth and evidence. The import of the following discussion will be that there are difficulties in giving any consistent analysis of knowledge expressions when these are used purportedly to convey information that there is evidence for the truth of some assertion and that the assertion is true. These difficulties suggest that certain limits are imposed on the usefulness of knowledge expressions, a conclusion that would provide philosophical support for the radical sceptic’s disinclination to affirm the truth of anything.

However, as in all arguments, the limits of our conclusions are as important as the conclusions themselves, and it will be necessary to note the restrictions that are imposed on them by the nature of the problem of knowledge as we conceive it. In particular, we shall have to guard against inferring from the fact that there are difficulties in giving a satisfactory account of knowledge expressions in terms of truth and evidence (or ground), the conclusion that these difficulties are in some sense “inherent in the very notion of knowledge.” As we shall see, there is no obvious connection between these difficulties and questions about whether knowledge is possible or not, that is, with the problem of knowledge as ordinarily conceived. On the other hand, they do have a bearing on the acceptability or possibility of radical scepticism, and the following discussion constitutes an attempted justification of radical scepticism. (As such, of course, it is not a justification that the radical sceptic could consistently accept; but if he were favorably impressed by the arguments, he might well employ them as counterarguments against those who dogmatically assert his own intellectual unresponsibility.)

The nature of the “problem of knowledge” as discussed here can be expressed in terms of the awkwardness of applying knowledge expressions when one takes into consideration the combined truth and evidence require-

ments of such expressions. This awkwardness can be expressed in terms of a secondary thesis that asserts the impossibility of identifying an event that constitutes the transition from reaching toward knowledge to grasping it. In fact, the metaphor of reaching, as also of arriving at, cannot be applied to any use of knowledge expressions that explicitly differentiates the truth requirement from the evidence requirement. To put it summarily, we might say that knowledge cannot be reached in such a sense by any increase of evidence.

Restrictions and Qualifications

Some restrictions and qualifications have to be made to the above theses. First, I provide no arguments to show that concepts of knowledge that definitely imply or definitely do not imply truth and evidence are the only ones possible. For example, I shall not attempt in this inquiry to refute certain versions of pragmatism and subjectivism. There is, however, general agreement that the concepts of knowledge that imply truth and evidence are the important ones in philosophical discourse. This seems to have been acknowledged ever since Plato.¹ Apparently Plato and Aristotle did not doubt that such knowledge could be and had been reached. Indeed, Aristotle is very specific in contending that knowledge of this kind is derived through evidence. Thus, one of his theses might be formulated as follows: in at least one sense of “knowledge” and “reaching,” knowledge implying truth and evidence is something that we *can* reach through an increase in evidence.

Second, although our secondary thesis about “reaching” does apply also to “arriving at,” it is not intended to cover a thesis about “having.” It is at least not clear that the inability to conceptualize arrival at knowledge entails the impossibility of having knowledge. Therefore the possibility that we do in fact know a great deal certainly cannot be excluded. All that is denied is that we can give any consistent account of our arrival at whatever knowledge we may have, and may have obtained.

Further, in many cases, the question of evidence and the description of steps of accumulation of evidence seem out of place. With respect to certain kinds of everyday utterances, we scarcely talk about evidence, collecting more evidence, and the like, at all. For instance, I do not speak about my evidence for believing that this is my finger or that it is not raining on this table. In the case of it being irrelevant to ask about evidence, the question

of how to arrive at knowledge by an increase in evidence does not arise. In what follows I intend to talk about utterances in which it *is* relevant to ask such questions as “What about the evidence?,” “How do you know?,” “What makes you so sure?,” “How did you find out?,” and so on. Thus, if I say I am in pain, the situation is mostly of a kind that makes the quest for evidence irrelevant or at least very queer. Notice that this restriction limits our discussions appreciably compared with Sextus’s and our own treatment of Sextus in chapter 1. Sextus discusses at length such sentences as “I feel hot now” and other utterances that in everyday life are not ever supposed to elicit a “What is your evidence (for such a conclusion)?” The question “What *kinds* of statement or what kinds of circumstances are such that the question of evidence is irrelevant or inappropriate?” is, of course, a formidable one, and cannot be taken up here. Some philosophers, John L. Austin among them, favor broad delimitations of the field of inappropriateness (see, e.g., *Sense and Sensibilia*, pp. 115 ff.).

The Shift from Plain Announcing of Knowledge, to Justifying Claims, to Saying One Knows

To claim that knowledge cannot be reached may seem counterintuitive. Perhaps it will be protested that there are cases in which it seems utterly clear that knowledge is reached, and by an increase in evidence. Until recently, for example, there was only relatively indirect evidence in support of the existence of high mountains on the other side of the moon. But then photographs became available. Surely, then, we can say that it is true that there are mountains, and that we know it, and that truth and knowledge were reached some years ago through a definite increase in evidence. If there is a problem here, it seems only to be that of the paradox of the heap, that is, of determining at which step of accumulating the evidence it became sufficient to establish truth—with which photograph and at what stage in its production did someone grasp the truth and thus acquire the knowledge that “there are high mountains on the other side of the moon”? But if one looks a little closer into the matter, the problem confronting the epistemologist appears more involved.

The way in which people use expressions of the form “N. N. knows that *p*” suggests a model in which certain situations serve as ideal examples.

Such models of “knowing that p ” assure a special kind of cognitive position or vantage point vis-à-vis the facts. When I say I know that something is the case, it is because I believe I am aware of the facts in some way analogous to direct perception of them; I and the facts are in the same sort of excellent cognitive relation. Just as I have things or events in view, so I have facts in my grasp. And just as I came to see things or events with my eyes, so I came to grasp the facts with my mind. Thus, prior to the photographs of the back of the moon, the facts were not grasped, but now that they are available, the fact that there are mountains there is a piece of knowledge in the hands of at least certain scientists and also perhaps of those who have seen or been told about the pictures.

The plausibility of this way of talking rests on the acceptance of certain situations as instances of the paradigm cognitive relationship. It is assumed that in certain situations we have not merely better evidence, but that the evidence we have is so good as to be tantamount to, or in some sense to guarantee, truth.

But it seems that to treat a situation as one in which truth recognizably accompanies the evidence involves an evasion or a denial of a basic fact: truth and evidence are *complementary* requirements of knowledge. Now, to describe these two requirements as complementary is simply to say that in order for “ p is known” to be true, there must be acceptable evidence for p , and p must be true. There is, it seems, nothing inconsistent in the assumption that the two requirements are on any occasion separately satisfied; to assert that p may be known is meaningful and consistent. But there is no way in which this can be more than an assumption. It is not possible, so far as I can see, to give an account of some situation in which that situation can be described as furnishing either two sets of denotata answering to the truth and evidence requirements or one set of denotata that truth and evidence share. There is, in fact, no identifiable situation answering to the paradigm cognitive relationship that knowledge claims assume and sharing the assumption that lies at the basis of the utility of knowledge expressions.

These considerations can be seen to emerge when pressure is applied to everyday uses of “I know” and similar expressions. Ordinary run-of-the-mill claims to know that something or other is the case are generally unproblematic. There are fairly clearly defined rules for making such claims, and for accepting or rejecting them. That is, expressions like “I know”

CONCEPTUAL COMPLEMENTARITY OF EVIDENCE

function satisfactorily for communication. But it seems that the utility of such expressions depends on the assumption or convention that evidence of a certain kind does constitute or guarantee truth, and hence knowledge. However, when pressure, even if only in the form of attention, comes to bear on this assumption, the complementarity of truth and evidence is exposed and the utility of the expressions rapidly diminishes.

When, for whatever reason, people go into the details of the evidence considering one piece at a time, I think most of them, whether they are philosophically sophisticated or not, tend (1) to stop using the distinctions between known and not-known and between true and untrue or (2) shift toward the question of being *justified in asserting or saying* "Now it is true" or "Now it is known." That is, there is a tendency to estimate what might be, from a social point of view, sufficient to claim this or that. "Nobody" will blame one for *saying*, "It is true that there are mountains on the other side of the moon, and at least some photographers are directly aware of the fact."

If, experimentally, we press people toward retaining the above distinctions, the results indicate a shift toward increasing indefinitely the requirements for grasping knowledge and for guarantees of truth. ("Of course one cannot be absolutely sure," "Naturally, there is always a chance of being mistaken," and so on.) Such increases in the requirements do not necessarily affect the consistency or constancy of the meaning of *truth* and of *knowledge* in everyday talk. The shifts are just part of the way the terms are used; they result in dropping certain terms and using others in their place. A sort of verbal evasion takes place: repeated posings of the question "Do you *know*?" after a while no longer elicit answers in terms of knowledge but in terms of evidence, "untranslatable" into answers in terms of reaching knowledge.

The transition from knowledge expressions to evidence expressions, the substantial increases or decreases of requirements, and concessions such as "Of course, one cannot be absolutely sure" that do *not* imply retraction of a previous "I know it": all these complicated mechanisms affecting daily use are relevant to attempts to delimit a meaning or connotation or a set of meanings and connotations of "knowing." Being conceptually indeterminate, so to speak, these mechanisms are not of a kind easily taken care of in ordinary definitions and explicit conceptual determinations (*Begriffsbestimmungen*) and are not easily adapted to formulation in terms of sets of constant requirements, criteria, or necessary conditions.

The same kind of shifts can be studied in other cases: Something is said to be known *now* but not to have been known at a previous date, and the difference is readily said to be due to an increase of evidence. But if, contrary to custom, detailed information is elicited concerning the way the difference was established, concerning the dates and the documentation and so on, there is a shift in the actual theme of the discussion from *being* true and known to *saying* that something is true and known, or from knowing to having evidence of this or that kind.

The distinction between asking “Is *p* true?” and “Is it justifiable to say (assert) *p*?” is a well-established one both in everyday life and in scientific contexts. You may say you are occupied (or not feeling well, unable to answer, etc.); that is, you may say these things even if you know they are untrue. It is perfectly justifiable to say you have found the solution. To say that you *believe* you have found it will give listeners a wrong impression—they will underestimate the evidence you have or assume you have none.

However, claiming that a difference is well established in everyday life and in scientific contexts does not necessarily imply that the definiteness of intention in communication is always sufficient to allow for the distinction to be intended. In fact, the distinction between “Is *p* true?” and “Is it justifiable to assert *p*?” is often slurred over, and in recent philosophical discussions this practice has received some encouragement, as we shall see. However, although there are well-established precedents both for making the distinction and for ignoring it, in what follows we must rely on making the distinction with great emphasis.

The conclusion drawn from empirical studies of cases in which people actually use the terms *true*, *known*, and *evidence* is, in short, *not* that they tend explicitly to give up or retract their claim to know, or that they soften the truth requirement, but that they continue the discussion as if the claim had not been made. The truth and knowledge claims are left alone: the speakers leave one subject of discussion for another—or so, at least, it appears from the point of view of the epistemologist. But, of course, a shift of ground is always relative to someone’s—usually theoretically determined—partitioning of the ground, and it is no doubt possible to redraw the boundaries in such a way that we should say there was no shift of ground.

Let us nonetheless conclude that, at least from the point of view of an epistemologist who cannot imagine a situation in which the known/not-

known distinction is inapplicable or can be misplaced, there is indeed a shift of ground, a *metabasis eis allo genos*.

Requirements of “Knowing” Involving Three Questions: Corresponding Questionnaires

There is, in recent philosophical discussions, a flourishing branch of the family of definitions or sets of definitions of knowledge, namely those requiring three things: that one be sure, that one have adequate grounds for being sure, and that what is claimed to be known be true.² I shall try in what follows to break through the barriers between epistemological discussion and empirical observation by asking, What would happen if we tried *to use* the three requirements in actual situations, if we asked whether a particular given statement fulfilled them?

Now any practical use of three such complicated decision criteria makes it necessary to apply them one at a time. But then this has a very serious consequence: Instead of a question that is timeless and abstract, we get one in which the order that three separate items are applied matters. There will now be *three* questions of the kind “Does this statement fulfill requirement *x*?” The three items may be interpreted as three necessary conditions. Together they have been considered to make up a complete set of necessary and sufficient conditions. And every time anyone correctly concludes that he or someone else knows something, it is presumed that the three questions have been given adequate answers, one for each necessary condition.

Let us call a standard set of questions asked in a definite, repeatable kind of situation a “questionnaire.” The requirements, if used explicitly, will then delimit a family of questionnaires. It seems that such a questionnaire cannot easily be avoided if, contrary to custom, the requirements are to be used or put forward explicitly in concrete cases, one after the other. Persons who want to act responsibly and to make sure that they themselves or others *know* that such-and-such is the case will have to remind themselves of the three questions, listing them in one of six possible orders.

The “Third-Person” and “First-Person” Questionnaires

If I am asked, “Does N. N. *know* that Leif Ericsson discovered America?” I may decide to use the following kind of questionnaire:³

Questionnaire 1:

1. Is he sure that p ?
2. Does he have adequate grounds for being sure?
3. Is p true?

In Questionnaire 1, (3) is clearly different from the conjunction of questions (1) and (2), provided *adequate* is defined in terms of certain (social) standards. But now we come to the problem children of our distinguished family, the criteria that I know that p :

Questionnaire 2:

I know that p —I am sure that p , I have adequate grounds for being sure that p , and p is true.

On questioning myself, or being questioned by others, as to whether I know p to be the case, what am I to do when confronted by the third requirement? What is the relation between the first two and the third for me, as I'm on the point of deciding whether I do or do not know that p is the case? Is it really a new question? And if so, what can I provide in answer to it except repetitions of what I have already said?

For the sake of an easy survey, both the third-person questionnaire, in which I answer questions about another person and the first-person questionnaire, in which I answer questions about myself, may be formulated thus:

Questionnaire 3:

- | | |
|---|---|
| 1. Is he sure that p ? | Am I sure that p ? |
| 2. Does he have adequate grounds
for being sure that p ? | Do I have adequate grounds
for being sure that p ? |
| 3. Is p true? | Is p true? |

When deciding whether *he* knows, I answer the question "Is p true?" on the authority of my own beliefs and grounds—a basis not referred to previously in the questionnaire. The third-person questionnaire is, so to speak, that of a bystander, an observer, or maybe an editor of an encyclopedia of knowledge, like the one compiled by Otto Neurath (whose views about knowledge were described by Russell as characteristic of an editor, not a contributor).

CONCEPTUAL COMPLEMENTARITY OF EVIDENCE

On the other hand, when faced with the question “Is p true?” of the first-person questionnaire, I shall once more ask myself, “Do I have adequate grounds?” or search frantically for something more than evidence, say a guarantee of truth, a direct, transcendental insight into the nature of things. I must look for something that allows me to eliminate the *process* of knowing, of mediation. For I am no longer being asked about grounds; the positive answer to the question of adequacy of grounds remains unchallenged but seems not to be taken as sufficient.

If I have already answered yes to the question about adequate grounds, the question “Is p true?” will then tend to be interpreted according to a strong or a weak interpretation of “adequate grounds,” either as an awkward repetition of the question concerning adequate grounds or as an undecidable question, such as “Irrespective of my adequate grounds and my personal conviction, *is* there life on other planets?”

All through this discussion I have presumed that we are dealing with questions in relation to which the quest for evidence is relevant. In such cases, I know of no other basis except evidence for establishing truth and (true) knowledge. But, then, the third question, the truth requirement, cannot be taken as an independent requirement when an individual judges his own knowledge claims. And in that case, the third question is a misleading one.

This criticism of the set of three requirements for knowledge does not automatically apply to our consideration of the statements of *other* people. There we are bystanders, judges, sociologists, and editors. But maybe a simple change in the order of the stated requirements may save the three-requirement conceptions. Perhaps we should ask for truth first and evidence afterward. Chisholm, in *Perceiving* (1957), treats the truth requirement just as we have done so far, as the third requirement. But Ayer, in *The Problem of Knowledge* (1956), puts the truth requirement first. He writes:

I conclude then that the necessary and sufficient conditions for knowing that something is the case are first that what one is said to know be true, secondly that one be sure of it, and thirdly that one should have the right to be sure.
(P. 35)

Reformulated, this piece of text may well be taken as a member of the family of definitions under consideration, because Ayer makes the right to be sure depend on the satisfaction of certain standards of evidence.⁴ A first-person questionnaire adapted to Ayer’s point of view would run as follows:

Questionnaire 4:

1. Is what I say I know true?
2. Am I sure of what I say I know?
3. Do I have the right to be sure of what I say I know?

For the purpose of making comparisons with other questionnaires, let us reformulate these questions as follows:

Questionnaire 5:

1. Is p true?
2. Am I sure that p ?
3. Do I have the right to be sure that p ?

As in the case of the expression "adequate evidence," the expression "right to be sure" admits of a strong and a weak interpretation, according to whether or not one only has the right to be sure that p , if p is true. In the former case, truth is, in other words, taken to be a necessary condition for having the right to be sure, whereas in the latter case, it is not. The two interpretations may be formulated thus:

$T_0 \equiv$ adequate grounds

$T_1 \equiv$ grounds that according to prevailing standards are sufficient to justify my being sure

$T_2 \equiv$ grounds that are so good that if they are realized, then p is true

In the following I shall be assuming T_1 rather than T_2 , that is, I adhere to the "social standard" interpretation. A positive answer to (3) (in Questionnaire 5), using T_1 , amounts to a declaration that one acts as a responsible member of society. One can justify having answered positively, even if subsequent events should make it natural to conclude that p is false. This interpretation, in other words, provides for the eventuality that one was mistaken. If one was indeed mistaken, one nevertheless had the right to be sure.

The strong interpretation indeed is not the usual one among epistemologists. Thus, according to Ayer (1956: 43), one earns the right independently of the question of what will actually happen later. Later one may earn the right to retract the original claim. The right to be sure that p and the right to be sure that not- p are earned at definite dates by definite people. Thus, at

CONCEPTUAL COMPLEMENTARITY OF EVIDENCE

the same time as person *A* earns the right to be sure that *p*, *B* may earn the right to be sure that not-*p*. Hence, although the strong interpretation of “adequate grounds” and “right to be sure” makes the third question a repetition of the first, the weaker interpretation allows that one may have the right to be sure irrespective of the question of truth. That is, I may, for instance, have information that no one can reasonably expect me to doubt, but which in a particular situation is misleading. Thus, I will not reject the remote possibility that I am now in Africa, but I shall insist that I have the right to be sure I am in Europe. My evidence fulfills, I firmly believe, any reasonable standard of evidence, and I shall turn with indignation toward anyone who questions that I have at least the right *to say* I know I am in Europe. I may concede remote possibilities of *p* being false and at the same time insist on having the right to say I know that *p*.

After this digression on the expressions “right to be sure” and “right to say I know,” let us inspect our new formulation (5); let us call it the modified Ayer Questionnaire.

As an oral questionnaire, it is likely to be more successful than the previous first-person questionnaires, because the subject asks himself directly about *p* before he asks about his personal relations to *p*. Ontology precedes epistemology.

Empirical investigations have shown, however, that people, when asked about their relations to *p*, that is, whether they are sure and what evidence they have, tend to give up the simple straightforward expressions “It is true” and “I know” in favor of such expressions as “I am convinced it is true,” “I am perfectly sure it is true,” or the even more subjective “I am convinced” and “I am perfectly sure.” Both logically and psychologically, this shift of ground is significant. Expressions that refer to our own relations to the proposition are used when our attention is focused on that relation. One may conclude, maybe on the next day, “I was convinced it was true, but actually it was false,” “I was perfectly sure of it, but it was not so,” or “I was sure I knew, but I did not.” On the other hand, under these conditions one will not conclude “It was true, but actually it was false” or “I knew it, but it was false.” The difference is made even clearer if I say on the next day: “I said yesterday that I was *convinced* *p* was true. I *was* convinced that what I said was true. But, unfortunately, it turns out that *p* is false.”⁵

If, now, evidence increases—even with the force of an avalanche—(perfectly normal) people will still tend to continue to use the evidence-

centered expressions; they do not revert to the simple "*p* is true." More than that, explications of truth in terms of maximal evidence seem to be self-defeating, because nobody seems to have described a kind of actual evidence possessed or enjoyed by some actual person such that the mere having or enjoying of it automatically establishes truth. Changing the order of the questions consequently does not solve our problem of how to find a natural first-person questionnaire that combines the impersonal truth requirement and the personal conviction and evidence requirement.

By empirical methods of research, the shift from truth terminology to evidence terminology may be studied in detail. We shall see that it can be explained in terms of the conceptual framework of empirical semantics. However, before embarking we should perhaps accommodate those philosophers who are still reluctant to hand over to science what they can possibly discuss in their own terms and try to put the facts into frameworks that are more familiar to them.

Of these, the game framework is one of the most absorbing at the present time. One may conceive of a mother game (or point-of-departure game), the simply-telling-what-is-the-case game that, when certain constellations are reached, can start off two mutually exclusive subgames, the truth game and the evidence game. One must make a choice at the appropriate point, and then there is no way back. If one chooses the truth game, one must stick to its own bleak and depersonalized terminology using expressions without even an implicit reference to the problems and practices of justification, possibly just repeating the truth-claim. If one chooses the evidence game, one must describe, assess, and weigh evidence, using the complicated, rich vocabulary of the trades and sciences.

In choosing and playing the evidence game, one also starts off on a new round of the mother game: Weighing the evidence, you say that such and such *are* the sources of error, that some piece of evidence is better than another piece, and so on. If your partner introduces a knowledge game ("How do you *know*?") in relation to your statements about the evidence, the crucial-choice situation may turn up once again, and you will have to choose once more between the truth game and the evidence game. But the new, subsidiary play does not ruin the principal one; you may just go ahead, continuing the moves appropriate for the situation.

So much for the applications of game concepts to the problem. But there is another popular framework among philosophers: the transition

CONCEPTUAL COMPLEMENTARITY OF EVIDENCE

from truth to evidence or vice versa can also be conceived in terms of rationally reconstructed levels. When my attention is absorbed by the process of amassing evidence, the use of the expression "It is true" refers to second-order statements. Thus, I may say, "The evidence, it is true, has not increased to such an extent that it is simply crushing." Or we may say, "I am now perfectly convinced. That is true." Or we say, "Nobody can blame you, you were sure that the gun was unloaded. That is true. But you blundered when saying you *knew* it was unloaded."

If, being already at the second level, I start to reflect, the terms not referring to evidence and conviction disappear. If I have said "I am perfectly convinced that is true" and I am questioned about the honesty of my conviction, I shall speak of my *evidence* of the sincerity of my conviction, and this makes it difficult to revert to simply saying "It is true that I am convinced." The simple phrasing "*It is* true" may disappear only to reappear at the third level, and so forth.

Thus the shift from truth terminology to evidence terminology induced by applying the corresponding requirements separately can be neatly conceptualized; that is to say, it is possible in these terms, and no doubt in others, to provide a rational explanation of the change of ground. But what such conceptualizations so neatly express is precisely the disparity of the two requirements in their concrete application: the requirements, in short, are not *used* in such a way as to complement one another. One might say that the mistake such conceptualizations point to is that of inferring from the correctness of an analysis of "I know that *p*," in terms of two distinct requirements of truth and evidence, the conclusion that we explicitly require of particular knowledge claims that they presuppose separate answers to questions about truth and evidence.

Now this is of relevance for the analyses provided by Ayer and others who accept the three-requirement concept of knowledge. As concept mapping or rational reconstruction projects, such analyses may be helpful insofar as they abstract the logical implications of common usage. And yet, however faithfully these analyses represent the conceptual implications of "I know that *p*," it is important to see that the details of the analyses do not necessarily reproduce conceptual distinctions actually made in common usage. This can be seen by applying such analyses to concrete cases.

Suppose *A* asserts that he knows that *p*. If "I have adequate grounds for belief in *p*" and "*p* is true" are said to express two conditions for such an as-

sertion, the mere listing of them together by another person, *B*, in the presence of *A*, changes the whole atmosphere for *A*. The requirement expressed by "*p* is true" is such that it cannot be added to "I have adequate grounds for belief in *p*" without a change of attitude; when saying "*p* is true," attention is fixed on what is asserted by *p*. The combination of the two conditions requires of *A* that he maintain a combined externalizing and nonexternalizing attitude or that he oscillate rapidly between the two.

How is *A* to interpret *B*'s interference? In all likelihood *A* will interpret the second condition, the truth requirement, as a more exacting requirement than the first, but of essentially the same kind. Invoking the truth requirement makes *A* reconsider whether the grounds are really adequate. He will reflect, "Remember, it is a question here of what is the case, not merely belief or conviction; therefore be critical in your examination of the evidence!"

In other words, the effect of introducing the analysis to people engaged in assessing *p* is to bring pressure to bear on them to increase the standard of adequacy. And further, if they yield to the pressure, the effect will be to distort usage—in the form of the adoption of a terminology with unusually severe requirements for saying "I know that *p*" and "*p* is true."

Looking closely, then, at the empirical evidence on how we actually tend to behave in situations in which we are confronted with the three requirements, it seems impossible or highly unnatural to conclude anything in terms of conceptual constructions of knowledge. In applying the three requirements, we find no neat concept of knowledge such as an analysis in terms of them suggests. The material evidence, in fact, provides no indication of such a set of mutually complementary conditions in cases of the normal use of "I know that *p*."

Insofar, then, as a three-requirement analysis expresses a model of reaching toward truth and grasping it in a way in which it is guaranteed, it seems that the model does not apply. The model, or frame of reference, or metaphor for gradually reaching knowledge through increases in evidence simply cannot be adapted to summing up or conceptualizing the empirical material.

If I gradually come nearer and nearer to an apple, I can eventually grasp it. This latter event is clearly something very different from merely getting close to the apple. In reaching for something it is possible, for example, to reach too far in our eagerness or drunkenness. Having grasped it, one may lose one's grip. Or one may be forestalled by someone else reaching it first. All this contrasts with our striving or reaching for knowledge. We may in

some sense measure an increase in evidence, but we cannot measure the approximations to knowledge where knowledge requires truth. The event of grasping is just not forthcoming, and nothing corresponds to reaching beyond, losing one's grip, or being forestalled.

There are, on the other hand, some similarities between reaching knowledge and reaching apples. We may be mistaken in our belief that we have reached the apple. Darkness may make our judgment unreliable, or somebody may have put a wooden "apple" on the branch in order to teach us philosophy. But the clear and sufficiently relevant difference between reaching an apple and reaching a piece of knowledge lies in the conceptualization of the process. In order to reach the apple, one must not only come sufficiently near to it, something entirely new must happen, namely the actual grasping of the apple. And whether we are mistaken or not in believing it is a genuine apple, the actual grasping is conceivable and is conceived as an independent event providing a new kind of experience.

A Conclusion on "Reaching" Knowledge

If we conclude that knowledge cannot be reached by increasing evidence, it sounds as though we are playing into the hands of those who unduly stress human fallibility. But, of course, the formulation also covers knowledge about failures and errors. No belief can be *known* to be mistaken by increasing the evidence for its negation. So really the formulation indirectly supports infallibility as much as it does fallibility.

The formulation "knowledge cannot be reached by increasing evidence" is nevertheless misleading. What we have done is to consider some kinds of sets of proposed necessary and sufficient conditions for "knowing," especially for the truth of "I know that *p*." We have noted that when (a) "it is the case" requirements, and (b) evidence requirements are made sufficiently precise as separate requirements, there is no process comparable to a reaching and grasping of knowledge by increasing the quality of evidence. But it is just because there is no such process that the negative, sweepingly general conclusion—compared with the narrowness of the kind of requirements we have considered—may be misleading. It might lead one to think that *reaching* is in any case a good conceptual frame of reference in relation to knowledge, whatever the level of preciseness of the discussion. The empirical material, however, suggests otherwise. It might be less misleading, then, to say

“Knowledge defined conceptually in terms of requirements can neither be reached nor not reached by increasing the evidence” or “The metaphor of reaching out for, coming gradually nearer, and then eventually grasping is inadequate as a basis for a conceptualization or explication of ‘knowledge.’”

Even this formulation is not an entirely satisfactory one since the inadequacy, as far as we have discussed it above, refers to a process of increasing evidence, which is only one process by which knowledge is obtained. We have not discussed, for example, the possibilities of immediate intuition.

Nevertheless, our conclusion has severe repercussions for the three-requirement conceptions of knowledge. For it undermines the assumption that there is any basis in how we commonly use “I know (that such and such is the case)” for constructing a concept of knowing that contains both a truth requirement and an evidence requirement, *each of which must be separately fulfilled*.

Now this last qualification might be taken to suggest an alternative solution. If our conceptualization of normal uses of “I know (that such and such is the case)” fails just because it demands that the truth and evidence requirements be separately satisfied, why should we not construct a concept in which the requirements do not require separate answers? That is, why not take the problematic truth requirement to be satisfiable in terms of the unproblematic evidence requirement?

Concepts of Knowing Without a Separately Satisfied Truth Requirement

Insofar as claims to know that such and such are typically accepted or rejected on the basis of evidence—either the evidence attributed to the claimant or the evidence the attributer attributes to himself—such a conceptualization might seem to do justice to ordinary usage. But although the proposed conceptualization agrees with ordinary usage in respect to making the evidence requirement the working partner, it departs from ordinary usage in making the truth requirement entirely subordinate to the evidence requirement. What the proposal requires is that we make do with evidence alone, that is, determine knowledge (and thereby truth) exclusively in terms of specified standards of evidence.

Now if the truth requirement and the requirement of adequate evidence are collapsed in this way, it is clear that I can still rationally reconstruct the

CONCEPTUAL COMPLEMENTARITY OF EVIDENCE

process of reaching knowledge. For if the evidence according to a social standard is less than adequate, then an increase in evidence will eventually make it adequate. There is no special difficulty involved as long as adequacy is defined in relation to specified standards that have already been satisfied in other cases.⁶ Thus, if the presence of an eyewitness is taken as standard for certain kinds of assertions, the event of finding an eyewitness may at the same time be an event of reaching knowledge. Both events are datable, and there is no question of what happens afterwards.

There will even be levels of evidence that more than fulfill the standards, thus making it practicable to localize the lower limit of adequacy between two levels, the level of less than adequate and the level of more than adequate. Then the difficulties of grasping knowledge as a special event as opposed to approximating it naturally disappear.

There are, however, cogent reasons for rejecting definitions in terms of standards of evidence. They lead to paradoxes, or at least to terminological oddities that few would tolerate once they were made aware of them. In other words, this conceptualization of knowledge, just as the previous one, leads to perplexities and to a negative conclusion.

To see how this is so, consider the following tentative equivalences (omitting the “being sure” requirement for the sake of simplicity):⁷

- 1a. Knows now at time t that p : A 's evidence now at time t that p satisfies the standard of evidence valid now at time t in the field to which p belongs.
- 1b. Knew at time t that p : A 's evidence at some past time t that p satisfied the standard of evidence valid at time t in the field to which p belongs.
- 1c. Was mistaken at time t that he knew that p : A 's evidence at time t that p did not actually satisfy the standard of evidence valid at time t in the field to which p belongs.

Now, so long as we retain the conventional idea that standards of evidence are modifiable, the conceptualization of “I know” in terms of specific standards of evidence will clearly lead to paradoxes. Thus, the left-hand proposition (1a) is not contradicted by the following left-hand propositions of (2a) or (2b) in the case in which equivalence (1a) holds:

- 2a. Knows at time $t + 1$ that not- p : A 's evidence now at time $t + 1$ that not- p satisfies the standard of evidence valid now at time $t + 1$ in the field to which p belongs.
- 2b. Knows now at time t that p : B 's evidence now at time t that p satisfies the standard of evidence valid now at time t in the field to which p belongs.

In short, giving up the separate truth requirement results in concepts of knowledge according to which two contradictory propositions may both be known, or in concepts relative to time, situation, person, or materials of evidence.

If, on the other hand, we try to resolve the paradox by avoiding the relativity to person and time, we would have to allow that there could be standards of evidence that rendered mistakes impossible. But this would exclude the modification of the relevant standards of evidence. Yet surely if we ask ourselves in what cases we would accept that evidence implied incorrigibility, we would have to allow that even if there were cases, they would seem to be so rare and uninteresting in practical life that using "know" only in those cases would virtually render the term inapplicable.

It should be noted that even if there are statements known for certain to be true, this does not show that the certainty arises from *evidence* making mistakes impossible. And incorrigible statements may not even be true, let alone known to be true, since statements might be incorrigibly false.

In any case, insofar as the establishment of social standards of evidence is not a mere fiction, these standards are fixed at levels that can be disputed. Indeed, it is the disputable character of evidence that motivates the institution of standards. They also function to avoid too severe as well as too lenient requirements of knowing; they do not function to institute the severest possible requirements. The *possibility* of agreeing to the statement "It was generally accepted that we knew that p , but it was a mistake" is left open.

If we accept:

- 3. If at least one person knows that p , then p is known.

Then, if (1a) and (2a) are true we accept as possible:

CONCEPTUAL COMPLEMENTARITY OF EVIDENCE

4. Both p and not- p are known.

In general, the following constellations among others are possible if A and B are two different persons:

A knows that p , B knows that not- p .

A knew that p , A knows that not- p .

A knew that p , B knew that not- p .

The possibility is not to be qualified as *remote*, for even in scientific textbooks a considerable percentage of statements judged to express knowledge are retracted as time passes. Applying (3) we get a mass of combinations of the following kinds:

Now p is known, whereas earlier not- p was known.

Now p is known in the scientific community A , whereas not- p is known in B .

In a case in which standards in a field are successively increased in severity from level L_1 to L_2 , and from L_2 to L_3 , and so on, then “known” would have to be indexed:

Now p is L_3 -known (and therefore also L_2 - and L_1 -known), whereas earlier not- p was L_2 -known.

In the backward(?) community A , not- p is L_1 -known in B , p is L_2 -known in C , L_3 -known.

The contradiction or inconsistency can, of course, be avoided if we drop the notion “known” and adopt evidence-concepts, for instance: “N. N. had at time t standard evidence.” But although the more complex notion does not lead to contradictions, neither, unfortunately, does it solve the problems connected with “knowing.”

Note that the equivalences (1a) through (1c) make it necessary to retract the statement that p is known by N. N. only if certain historical investiga-

tions concerning *standards* lead to results that differ from previous ones. *New evidence directly concerning p is irrelevant.* It cannot change the verdict “N. N. knows that *p*,” because it relates to the present and cannot affect “N. N. knew that *p*.” Whatever the amount of evidence amassed in the future in support of not-*p*, the proposition “N. N. knew at time *t* that *p*” will be true. However, evidence that N. N. after all did not have the socially required evidence may result in a denial that N. N. knew.

One of the negations of (1a) and (1c) runs as follows:

- 5a. Does not know now at time *t* that *p*: *A*’s evidence now at time *t* that *p* does not satisfy the standard . . .
- 5b. Was not mistaken at time *t* that he knew that *p*: *A*’s evidence at time *t* that *p* *did* satisfy the standard . . .

And more complex statements:

- 6. *A* knows that *C*’s evidence at time *t* that *p* did satisfy the standards, but *B* knew that it did not.
- 7. *A* has standard evidence that *C*’s evidence that *p* was up to standard, but *B* had standard evidence that *C*’s evidence that *p* was not up to standard.

Consider guns. There are certain manipulations that once performed justify one in saying, “The gun is unloaded,” but, of course, very strange circumstances may occur such that one may later establish adequate evidence that it was, in fact, loaded. If N. N. had adequate evidence at one o’clock that the gun was unloaded but later at two o’clock obtained new evidence that it was loaded at one o’clock, he still *knew* at one o’clock that it was unloaded. In court he may say, “Yes, the gun killed the dog at about one o’clock. From that time I knew it was loaded, but just before that I knew it was not loaded. Because I knew it was unloaded, I have no responsibility for what happened to the dog. I agree the gun *was* loaded all the time, but for part of the time I *knew* it was *not*.”

If knowing is defined in terms of satisfaction of definite standards of evidence, however high, and one keeps the definition in mind—eradicating any association of knowing with truth and being-the-case—such pieces of conversation as the following could occur:

CONCEPTUAL COMPLEMENTARITY OF EVIDENCE

Several people knew he was the murderer, but of course, as you know, he was not. Among those who knew he was the murderer, there are still some who think they know. The rest know he was not, they knew only until last spring.

Or:

A is right in maintaining that the spectrophotometric method as used by astronomer *B* satisfies our standard of evidence, and that the radar method as used by astronomer *C* does so also. *B* found that the distance to the sun is smaller than k ; *C* found it is greater than k . In other words, *B* knew it was smaller, *C* that it was greater. It is therefore correct to claim, as *A* does, that in view of *B*'s and *C*'s results, we know both that the distance is greater and that it is smaller.

Finally, there would be extreme oddity in the account of scientific research. The scientist would continually be finding himself encumbered with truths that his later researches would strongly incline him to renounce. Rather than have so much conflicting, even contradictory, knowledge on his hands, his wisest course might be to consign all rejected theories to a closed file marked "knowledge," and be content to concentrate henceforth on untruths. Or perhaps the natural result, both in scientific and everyday matters, would be a kind of despairing reappraisal of all past efforts and a sceptical pronouncement that none of the evidence obtained so far was correctly taken to guarantee, or to be tantamount to, the truth. The file marked "knowledge" would then have to be emptied.

So much, then, for the bold decision to conceptualize knowledge and truth in terms solely of evidence. If carried out, the use of the term *know* would differ so much from most usages relating to "know that p " as to be grossly misleading. If knowing is to be equated with having evidence of some kind, it would be better not to use the term *know* but to speak simply of having evidence of this or that particular kind, or simply of having standard or adequate evidence.

The conceptualizations of "It is probable that p " are mainly in terms of evidence. Attempts to conceptualize "I know that p " in terms of "It is very probable that p " therefore do not avoid the possibilities of both p and not- p being known. Lack of space forbids our going into detail concerning the complexities of probability constructs.

A Suggestion Not to Use Knowledge Expressions Under Certain Circumstances

In the foregoing I have argued that to require truth and evidence as two clearly separate, precise requirements of knowledge leads to the conclusion that we can never *reach* knowledge by an increase in evidence. If, on the other hand, we leave out truth as a distinct requirement and limit ourselves to requiring standard evidence, we get a strange use of “to know,” and we might as well eliminate the truth in favor of the evidence terminology, or, even better, in favor of a combined statement of degree and a kind of conviction or belief and status of evidence (grounds included).⁸

What we can conclude validly at this point must be carefully distinguished. All we have indicated is that it is difficult to make sense of the idea of attaining knowledge solely on the basis of evidence when the transition from not-yet-knowing to knowing is marked by some identifiable event. It is important to note two consequences that do not follow from this conclusion. First, it does not follow that we do not or cannot know anything or even that it is less probable that we know anything. The difficulty we have discussed is that of identifying any event as the transition point at which a mere belief becomes a true belief or at which a true belief becomes a belief known to be true. From this we can conclude at most that we cannot conceptualize our use of expressions of the form “I know that *p*” when we intend them to convey information about such an event. But, of course, it is doubtful whether the impossibility of identifying such an event means that an event of the kind in question cannot occur. At least this would require other, debatable, premises. Therefore not only does the possibility of our having knowledge remain open, in terms of the above discussion, but also the possibility of our arriving at or coming *somehow* to knowledge. What is excluded, however, is the possibility that we can conceptualize and point to an event that we know constitutes our arrival at knowledge.

The second main consequence that does *not* follow from the conclusion of our discussion is that expressions of the form “I know that *p*,” and other knowledge expressions, cannot be used in their normal sense for purposes of satisfactory communication.

As I shall try to show, the ordinary and normal use of such expressions does not require that the event of reaching knowledge be clearly distin-

guished from that of obtaining certain standard or accepted evidence. Nor does it require that it *not* be so distinguished. Such requirements are parts of explicit conceptualizations. It is only when knowledge expressions are used to express these conceptualizations that any difficulties arising out of the requirements affect their utility or smooth functioning. In the great majority of cases, explicit conceptualizations do not enter into, and thus do not determine, our use of such expressions. With regard to "I know that *p*," in cases in which the requirements of evidence and truth are not explicitly made, therefore, I suggest that the use of knowledge expressions is unproblematic. Thus, what I propose is that one may persist in using the terms *know* and *knowledge*, but only in situations in which it is taken for granted by the language community, or at least by the persons I speak to, that I do not make definite *conceptual requirements* concerning what is implied by something being known.

In seeking to justify the decision to persist in using the terms, therefore, I point to the term *know* as a term of everyday use that is applied with a certain lack of definiteness or depth of intention in relation to any conceptual framework. This lack of definiteness of intention, so I shall argue, is such that although in their everyday use of knowledge expressions, people implicitly acknowledge that what is false cannot be known (for example, when they come to believe that not-*p*, they withdraw any previous claim to know that *p*), they do not go so far as to *affirm* that what is known cannot be false or that it can. And it is because they do not think through the implication that they are able to envisage identifiable events that constitute not merely the addition of further evidence but the arrival at the truth of the matter itself. When we talk about the truth requirement, therefore, as far as ordinary use goes, neither the affirmation that what I know *cannot* be false nor the affirmation that it *can* will be to the point. They are both beyond what I can be presumed in everyday life to have thought about and to be able to understand and articulate. Thus, my usage will be a function of the definiteness of intention consistent with the context in which I use the terms *know* and *knowledge*.

It seems that the above considerations impose distinct limitations on the applicability of knowledge expressions, limitations that concern the use we have for the distinction between knowing that such and such and not knowing that such and such. We can put this more explicitly by saying that the considerations limit the range of situations in which an affirmation

that we do have knowledge or an affirmation that we do not have it functions informatively. To conclude that in such situations the distinction is reasonably withheld would be to argue for suspension of judgment, and in what follows I shall argue for the decision to abstain from trying to use the distinction between knowing and not-knowing in three—in part overlapping—kinds of situations. This amounts to a rejection of any yes or no answer to the question “Can knowledge be reached?”

First, though we *affirm*, for instance, the principle of contradiction, we nevertheless delimit the scope of the distinction in such a way that it does not make sense to state that the principle furnishes an instance of knowledge or of lack of knowledge.⁹

Aristotle himself argued against the application of the term *knowledge* (*epistémé*) to first principles (*archai*). The principle of contradiction does not rest on evidence, he contends, because to accept a proposition on the basis of evidence already presupposes that the principle of contradiction is true. And since one cannot be said to know something without implying that one can point to evidence, the principle of contradiction is not an instance of knowledge. In saying that one does not and cannot *know* any principle, however, Aristotle did not imply that we are not in possession of its truth. He seems rather to have meant to reject not only the status of knowledge but also the *distinction* between known and unknown with regard to the principles.

Today Aristotle would have some support in contending that we possess certain truths without evidence, but there are also strong movements in favor of looking at such “truths” as presuppositions, postulates, basic assumptions that are neither true nor false. (This would be my position, but it will not be relevant in arguments put forward here.)

Second, there is the situation of scientific research. The rules or principles of research methodology are such that at no point is the evidence for a proposition (if there is evidence for it at all) such that it cannot be increased. The rules themselves point out the ways of increase. The weight of a piece of evidence, for instance, a document containing the report of a set of observations, inevitably decreases with time—after a sufficiently long time it comes into the hands of critical historians who apply their own cold rules for assessing the weight of written sources. As long as this development is kept in mind, there is no occasion, except in popularizations, for using the knowledge and truth terminology.

CONCEPTUAL COMPLEMENTARITY OF EVIDENCE

The basic methodological model in conceptualizing the relation between a proposition of research and its reference is such that there is no necessary connection between evidence and reference: Whatever the evidence, the proposition may or may not be true. The status of evidence is in principle irrelevant because it is constantly shifting, whereas the proposition is either true or false all the time. If there is any kind of implied sceptical bent in this, and I think there is, then it is one that cannot appropriately be formulated in terms of knowing. For reasons already stated, to say that knowledge *cannot* be *reached* would be misleading. The terminology of evidence, confirmation, and corroboration is fitted to the model of unending research.

Although one may speak of a community of researchers, it is not of the kind in which one researcher “*vouches* for the truth” (Ayer 1956: 17)¹⁰ of what he or others say. Vouching, swearing, promising, or pledging one’s honor have no place in scientific methodology. The term *scientific knowledge* is widely used among researchers when talking about comprehensive sets of sentences, but in the more professionally serious and heavily conceptualized parts of their articles and books “I know that such and such” and related phrases are rare. There is little importance attached to considerations about which propositions have and which do not have the status of knowledge. Thus, to refrain from using knowledge expressions in scientific texts does not create any problems affecting research communications and is a common practice.

Use of “Know” and Definiteness of Intention

We have mentioned as an explanation of the fact that vernacular distinctions between what is and what is not known and between knowledge reached and knowledge not reached do not always work, a factor that we have termed *definiteness of intention*.¹¹

The general idea of degrees of definiteness of intention is as follows. When, under definite circumstances at a definite date, I use a sentence (or, more generally, an expression) to express something, I intend just this something and nothing else. Reflection, perhaps provoked by questions I myself or others pose, may, however, show or suggest indefiniteness in the form of vagueness or otherwise respecting the borders between the intended something and other things.

Certain distinctions may or may not have been present to my mind, or have been present with varying degrees of clearness. Or, although introspection does not reveal any such conscious distinguishing, nevertheless subsequent events both of a verbal and a nonverbal kind may allow us to posit that the distinctions were used. They were available or presentable to my consciousness even if they were not in it (*prebewusst*, or "preconscious," in the terminology of Freud).

Using an expression like "I know that such and such," it may be present to my mind or at least presentable that certain requirements (for instance, honesty and correct grammar) are (or are not) fulfilled. The definiteness of intention *in the direction* of one kind of requirement, for instance, concerning the distinction between true and false, may be sharp, but in other directions, say, concerning the distinction between truth and evidence, it may be small. In that case, although I may be able to report that in saying "I know that such and such" I implied that such and such is *true*, the question of truth may not have been present to my mind as a separate question from that of evidence. Confronted with the question of the quality of my evidence, I may report honestly that in saying I knew, I intended to require good or sufficient evidence and found the requirement satisfied, but I did not make a distinction between that and truth. Or else I find that to some extent I made a distinction and took it for granted that with such good evidence truth was guaranteed, or just there as a corollary. A great variety of other kinds of reports may be had from persons (professors of philosophy and others) trying to find out what they intended when they said they knew such and such.

Measurements of definiteness of intention can be surveyed by maps showing various directions of what I term *precization*. If T_0 is a sentence, say, "I know that Columbus discovered America in 1492," more precise sentences (which are not interpretations of each other), let us call them T_1, T_2, \dots , represent main directions of precization. Sentences still more precise than T_1 may be symbolized by T_{11}, T_{12}, \dots . The limit of the definiteness of intention of a person who has uttered T_0 is indicated by reporting which sentence is just within and which sentence is just beyond the discrimination of that person. Thus, one person may have intended something in the direction of T_2 (rather than T_1, T_3, \dots), but did not take into account the differences between T_{21}, T_{22} , and so on. Another may have intended T_{22} , but did not have sufficient definiteness of intention to discriminate be-

CONCEPTUAL COMPLEMENTARITY OF EVIDENCE

tween T_{221} , T_{222} , etc. He neither meant to express T_{221} nor *not* to express T_{221} . They are transintentional.

Let us now apply this apparatus:

$$1. T_0 \equiv \text{I know that } p$$

As first-order precizations, we could take some of the different conceptualizations in terms of three requirements. But we should also take some other formulations, as follows:

$$T_0 \equiv \text{I know that } p \left\{ \begin{array}{l} T_1 \equiv \begin{array}{l} \text{I am convinced that } p \\ \text{I have adequate evidence that } p \\ p \text{ is true} \end{array} \\ T_2 \equiv \begin{array}{l} \text{I believe that } p \\ p \text{ is true} \end{array} \\ T_3 \equiv \text{I have adequate evidence that } p \\ T_4 \equiv \text{I have verified that } p \\ T_5 \equiv \text{I am willing to vouch for } p \end{array} \right.$$

Many people have a definiteness of intention that is insufficient to discriminate even these first-order precizations. (They may show very sensitive discriminations, but not exactly in the directions listed.)

In order to explore the limits of the definiteness of intention among those who intended something like T_1 by T_0 a selection of second-order precizations must be used. They can be constructed on the basis of the following two sets of precizations of certain parts of T_1 and by precizations of a third sentence W_0 :

$$U_0 \equiv \text{I have adequate evidence that } p \left\{ \begin{array}{l} U_1 \equiv \begin{array}{l} \text{I have evidence satisfying the social} \\ \text{standard valid for the field to which} \\ p \text{ belongs, and justifying my saying} \\ p \text{ is true} \end{array} \\ U_2 \equiv \text{I have such good evidence that it is} \\ \text{unreasonable to doubt that } p \text{ is true} \\ U_3 \equiv \text{I have conclusive evidence that } p \end{array} \right.$$

$$V_0 \equiv p \text{ is true} \left\{ \begin{array}{l} V_1 \equiv \text{there is conclusive evidence that } p \\ V_2 \equiv \text{it is the case that } p \\ V_3 \equiv p \text{ belongs to an all-embracing} \\ \text{coherent system} \end{array} \right.$$

One of the precizations of U_0 is in all relevant respects identical with one of the precizations of V_0 . For those who by U_0 intend U_3 and by V_0 intend V_1 there is no special difficulty in answering both questions: "Do you have adequate evidence?" and "Is p true?" They take the questions to mean the same thing.

The other combinations (U_i, V_j) may be put in two classes: those for whom a positive answer to U_0 somehow implies a positive answer to V_0 , and those for whom V_0 is an entirely new proposition. For those who allow V_0 somehow to be implied by U_0 , a set of precizations of the expression W_0 ; if U_0 , then V_0 is worked out. Its function is to elicit reactions showing exactly how individual persons think U_0 is connected with V_0 .

The working hypotheses based on preliminary empirical findings are as follows:

1. Most people have a definiteness of intention using "I know that p ," and closely related sentences, that falls short of T_1, T_2, \dots
2. Very few people have a definiteness of intention sufficient to discriminate T_{11}, T_{12}, \dots
3. The smooth application of "I know that p " is hindered as soon as the precizations T_1, T_2, \dots are applied, and very strongly inhibited if T_{11}, T_{12}, \dots are applied.
4. Those who intend something definite in relation to first- or second-order precizations have difficulties in being consistent.

In this last hypothesis I refer to reactions to questions relating to evidence gathered by A supporting p and by B supporting not- p . People get into trouble when they are made aware of the possibilities of contradictions.

The general conclusion to be drawn is this: The use of "I know that p " has limited applicability. It cannot be mapped out in relation to a set of precise concepts; it works as long as such relations are ignored.

One of the reasons why it is rather difficult to keep variations in definiteness of intention in mind is that these differences are not usually indicated by separate words or phrases. To use such phrases as “loosely speaking,” “vaguely suggested,” or “with not too great an emphasis on unambiguity” would help very little and could make texts unreadable, or at least unread.

The statement on page 78 (under the heading “Requirements of ‘Knowing’ . . .”) is a case in point. Three “things” are “required,” and the requirement is then formulated in very loose words, considering the complexity of the subject. The first requirement, that one must be sure, is suggested by the vague words “one must be sure.” Some people tend to interpret these words in the direction of an actually felt, strong conviction. But in that case, many instances of “know” would be misuses, because claims to know are by no means always accompanied by any such strong feelings. Especially in the case of textbooks, or of a lecturer repeating certain statements for the tenth time, the only feeling to be experienced is likely to be one of boredom.

So there are a *variety of requirements* that might all be loosely expressed by “one must be sure.” Indeed, the phrase may not be so bad as an initial formulation, chosen because of, not in spite of, its indefiniteness, as is precisely the case on page 78, where in order not to close the doors to a number of interesting and relevant requirements, the formulations are purposefully kept vague.

But there is something more important to be remembered. Saying, as I have just done, that there are a variety of requirements that might all be loosely expressed by “one must be sure” (T_0), it is suggested that by taking a step toward clarification I could propose at least two formulations (T_1 and T_2) that in a simple, unambiguous way express two definite requirements, R_1 and R_2 . Implicit in this suggestion is that I have two such requirements “in mind,” that they exist already, and that the only question is how to express them.

The principle of limitation and relativity of definiteness, however, goes against this simplistic view of the situation. In order to bring out the full consequences of this principle, we need to substitute for the concept of precization that of direction of precization.

If T_1 and T_2 are two precizations of T_0 , and T_{11} and T_{21} are two precizations of T_1 and T_2 , two main directions of precization are indicated: that from T_0 through T_1 and that from T_0 through T_2 . There is in theory no halting place or end, but it is convenient to talk *as if* there were. We say

that "to be sure" may mean this or that, mentioning two precizations. These are taken as expressive of two concepts of being sure. But it would be better to talk of concepts in the direction of such and such and concepts in other directions, taking precizations as indicators of directions.

Applying this to what we have been calling "requirements," we may now talk of sets of three requirements (each ad hoc), delimited by three expressions, namely those used on page 78. That is, those expressions are used as initial formulations (T_0 , U_0 , V_0).

The question "Do everyday uses of 'I know that p ' satisfy the three requirements" may now be restated so as to avoid an important impasse:

Do everyday uses of "I know that p " satisfy the three requirements at least at one level of definiteness of intention and, if so, at what level?

This new way of putting the question does not exclude the possibility that one answers yes in relation to certain levels and no in relation to others.

From this new point of view, it is also clear that to speak straightforwardly about requirements is only justifiable in a very tentative manner: it may be that to people in a particular discussion no definite requirements are intended, in the sense that all the participants may have deliberately limited their definiteness of intention.

What is intended when an expression like "I know that p " is used in everyday situations is mostly and on the whole *not definite enough* in relation to questions of evidence and truth to warrant any explication *or* precization in terms of definite sets of precise requirements involving conceptualizations of "evidence" and "truth." All such sets of requirements will therefore represent transintentional entities—entities going beyond, but not necessarily against, the intention of the speaker, writer, or listener. If transintentional precizations of "I know that p " pointed in one main direction, furnishing consistent concepts of knowledge, it might not be highly problematic to use "I know that p " in situations in which it is necessary to show great care concerning the status of p . But epistemological discussion shows that vast difficulties have to be surmounted in order to find even one consistent trans- (but not anti-) intentional concept. The most reasonable policy is therefore to avoid the expression "I know that p " in situations in which a considerable definiteness of intention is required concerning that status of p .

CONCEPTUAL COMPLEMENTARITY OF EVIDENCE

The third kind of situation in which the use of the terms *know*, *knowing*, *knowledge*, and so on, are not to be recommended can therefore be described as the kind of situation in which a definiteness of intention in epistemic matters is required that goes beyond that of everyday situations. By epistemic matters, I refer to questions concerning certainty, evidence, and probability. Thus formulated, the third kind of situation may include instances of the two foregoing.

Expressions of the form “I know that *p*” lead to satisfactory communication if the required definiteness is low. The expressions “I have adequate evidence that *p*” and “*p* is true” function satisfactorily if used separately. What does not succeed is to explicate the first in terms of the last two. It does not succeed because, as we have seen, conceptual clarification of the terms involved makes it impossible to apply the metaphor of reaching truth when establishing truth is taken as a separate concept from acquiring adequate evidence. And if it is not taken as separate, the consequence will be that contradictory propositions can both be known. (Thus “I know that *p* and he knows that not-*p*.”)

Increased definiteness of intention shows itself in the application of a more discriminating set of distinctions. The third kind of situation might therefore also be described as situations in which a set of precise distinctions is presumed to be applied that is foreign to or inconsistent with the vernacular use of *know*, *knowing*, and so on. The notion of definiteness of intention is useful in order to make clear what kind of inconsistency is relevant here.

A Conclusion on the Complementarity of Truth and Evidence

That under certain conditions a set of distinctions implied by knowledge expressions cannot be usefully applied is a sufficient basis for recommending that the corresponding affirmations “I know” and “I do not know” be withheld when these conditions are valid. Under these conditions, then, it is reasonable to withhold judgment. According to the arguments, the only cases in which the conditions preventing applicability do not hold are those in which knowledge expressions are used with limited depth of intention, in fact when they function not to convey clear and precise distinctions, but as more or less conceptually innocent gestures, something approaching the “utterances” or “sounds” (*fonai*) mentioned by Sextus Empiricus (see

page 7) in connection with the sceptic's avoidance of doctrinally contaminated ways of expression. Thus the force of our discussion on the complementarity of truth and evidence is such as to bring out the strength of Pyrrhonian scepticism as described by Sextus.

The awkwardness of applying knowledge expressions when they are intended to convey in any precise manner the distinction between truth and evidence makes suspension of judgment at the corresponding depth of intention reasonable. When the depth of intention is such that "I know that p " implies complementarily that p is true and that I have evidence for p , the affirmation expressed by "I know that p " no longer has the applicability that the same expression has when the truth and evidence requirements are not intended as complementary. Thus, the applicability of a claim to know that such and such is a function of depth, or definiteness, of intention.

When depth of intention precludes the application of a knowledge expression, it does not, of course, follow that the statement expressed by it would be false. Our conclusion that in certain circumstances the application of knowledge expressions becomes awkward is not to be taken to justify a general negative conclusion about the possibility of knowledge, nor even about the difficulty of acquiring knowledge in these circumstances.

Nor are we to infer that because the application of knowledge expressions depends on certain distinctions not being made precise, these expressions "really" have no application, that their only possible use amounts to misuse. What has been pointed out is only that there are good reasons for not using knowledge expressions in certain circumstances, the circumstances in question being those in which the truth and evidence requirements of knowledge are conceptually distinguished. It is not implied that because in the vernacular use of these expressions there is a failure to think this distinction through, such use is in some sense debased. The inapplicability or awkwardness of a vernacular term in certain kinds of situations should not be taken to indicate an imperfection in the vernacular, but as a warning that the limits of the area of useful application of certain terms are sometimes closer at hand than one might expect.

V

Dialectics of Modern Epistemological Scepticism

Introduction

A good deal of contemporary discussion about knowledge incorporates arguments attributed to “the sceptic.” But as we have seen, this figure is a very different person from the sceptic outlined by Sextus Empiricus. Typically, scepticism is treated as a position that, if true, would be fatal for any attempted *philosophical* justification of ordinary notions of everyday or scientific knowledge. In fact, it might not be inaccurate to say that the position has been generated out of the very attempt to provide such a justification; at any rate, the significance of the modern sceptic’s arguments lies precisely in their power to demonstrate that no such attempt can succeed. Sextus Empiricus would label those who hold such a position Academicians, people who hold an absolutist kind of view that he clearly distinguishes from the “way” of the sceptic.

The modern sceptic, or epistemological sceptic, is made to argue that knowledge is impossible, to *insist* that we cannot know anything, to *affirm* that it is true or can be known that knowledge is not possible.¹ Naturally enough, although this sceptic’s arguments are taken seriously and some steps toward them are even accepted,² the position they support is not one that any flesh-and-blood philosopher is anxious to occupy. Indeed, to be forced to do so would most likely be seen as a professional defeat by those who look on the philosopher’s task as that of explaining, rather than replacing, well-established everyday beliefs. It is because the sceptic’s reasoning is considered intuitively false and yet logically impeccable that “his” arguments are subjected to close and careful epistemological scrutiny. Two features of modern accounts of scepticism are significant to our discussion, their avoidance of contextual considerations and the elaborate terminology and conceptual structures in which the arguments are framed. A typical proce-

ture is to consider with regard to some statement whether there are sources of error such that later events might cause one to retract a claim that the statement is true. If not, then the statement is "incorrigible," and we have no right to persist in refusing to affirm its truth on the grounds that it might be false. If there are conceivable sources of error, then the statement is "corrigible," and we are faced with the problem of whether or not we can "legitimately" claim to know that it is true.

To cope with this problem, a number of concepts are then introduced and developed. The effect of this is that the question of whether it is correct to use expressions of the form and normal intent of "I know that *p*" becomes a matter to be dealt with within an elaborate conceptual framework. The assumption is that such frameworks provide the terms in which a *general* question of justifying knowledge claims is to be answered. This general question is then treated as something over and above the question of particular contextual justifications for the use of expressions ("Should I have said 'thank you?' "). The epistemologist presumes his conclusions to apply in all contexts. Although he acknowledges that for all practical purposes there is no need to refer to his arguments, he thinks of them as showing us what, strictly speaking, we can or cannot say. The assumption seems to be that any well-equipped society catering to the enlightened interest of its members would make philosophical conclusions about knowledge available publicly, perhaps in reference libraries or, better, as an addition to the telephone service so that people could at any time or in any situation or stage of debate be given the authoritative view on the matter. (We might sympathize with the unfortunate man entrusted with the task of compiling such conclusions. Faced with arguments, authoritative and apparently technically proficient, to the effect that "material object" statements are/are not conclusively verifiable, that perception is a direct/indirect relation, and if indirect that "perception" statements then can/cannot be known with certainty to be true/false, that in making such statements we make/do not make inferences that, if we are to justify the claim to know such statements to be true must be/need not be valid inferences, and so on, he would almost certainly recommend suspension of judgment in his letter of resignation. Strictly speaking, of course, any headway he made would only add to the confusion.)

To deny that there were general questions about the applicability of knowledge expressions besides the considerations of context would be fruitless. It is a matter of fact that people ask them. But when they are asked and

answered in terms of explicit conceptual frameworks that have no part in ordinary usage, the relevance of the answers to ordinary knowledge claims becomes problematic.

The problem can be thus posed: does epistemology concern knowledge claims in general or knowledge claims only as they are understood by epistemologists, that is, in their own special frameworks? If the former, then we must suppose that the typical epistemological conclusion—for example, that knowledge claims about material objects cannot be justified—leaves the ordinary kinds of justification intact. The latter are all right in their place, and it is not for the epistemologist to question, say, the standards accepted among bird-watchers or people who want to know the time. He does not wish to pose as a more conscientious bird-watcher and time-teller; nor does the epistemological sceptic conclude that no bird watching or time telling can be conscientious enough. Rather, he questions whether the standards accepted by bird-watchers and time-tellers amount to valid inferences, whether they allow us to bridge “logical gaps,” and so on. The question of justification, therefore, is one that he takes up at a quite different level and in a terminology quite alien to that of the average, or even exceptionally scrupulous, bird-watcher or time-teller. His attitude, in fact, is parallel to that attributed to the sceptic when, as we noted in an earlier chapter, he is said to arrive at a *modus vivendi* by accepting that it is one thing to live (to watch birds and tell the time) and another to philosophize (to make valid inferences and legitimate claims). Then, however, we pointed out that since the Pyrrhonian sceptic accepts no philosophical framework, this *modus vivendi* is not available to him. In effect, a justification of Pyrrhonism is based on the fact that he can respond to his surroundings verbally, and in other ways, in a manner that does not require a corresponding response to propositions. Thus, he is not compelled to adopt two minds toward a proposition, one practical and the other theoretical. The propositions he is asked to accept on the basis of his experiences have a depth of intention that bears no comparison with that of his own straightforward acknowledgments of the appearances.

This suggests a totally different view of the significance of epistemological discussion, and it is this view, the second alternative, that we shall explore now. We shall look at philosophical discussions of knowledge as linear extensions, a kind of tenacious continuation, of ordinary dialogues with a stress on explicit frameworks that is not found in the initial stages. In-

stead of regarding the epistemologist as an *ex officio* member of the community, we shall see him as a participant in a comparatively rare kind of dialogue with a stress on explicit frameworks. The effect will be to present his conclusions, in particular sceptical conclusions such as “Nothing can be known” and “No statement can be known to be true,” as statements in need of severe qualifications.

Standards Relative to Stage of Dialogue

Our main task will be to explore, first, the kind of debate or sets of verbal exchanges that foster or tend to foster (modern) scepticism, and second, the possibilities of rationally reconstructing such a tendency. This line is adopted because it seems to me that despite the wide acceptance of the view that we ought, as philosophers, to appeal to particular situations or occasions, there has been a sad and significant neglect of one kind of situation, namely that which occurs as a link in a long chain of discussion. Such links, and the chains they help form, bring out an important aspect of the use of language that can do much to illuminate the dialectics of modern scepticism.

Philosophically, the most familiar kind of verbal chain of discussion is the dialogue, and the points I would like to elaborate here arise from simple considerations of the way in which, after three or four exchanges of views in a dialogue, an expression like “I know” can come to be used in a number of quite different ways.³ More particularly a use of “I know that *p*” at the opening of the debate may be very different from an “I know that *p*” repeated after a long argument for and against *p*. The claim to know at the opening of the dialogue could be an innocent offhand gesture compared with a coolly insistent stand in the face of arguments and after extensive deliberation.

It is because of this stress on developing dialogues that I call my notes on modern scepticism dialectical. Perhaps I should apologize to Hegelians for this old, but not very profound or Hegelian, use of the word, and to Austini-ans for employing such a pretentiously solemn one.

Consider first this example of a simple dialogue and its consequences for the use of “I know”:

1. A: Do you know where Mr. Jones lives?
2. B: Certainly I know. 12 Park Avenue.

3. *A*: Letters to him written to that address are returned by the post office.
4. *B*: Is that so?
5. *C*: Do you know where Mrs. Jones lives?
6. *B*: Mm, I was sure 12 Park Avenue was correct. But after what you said—I'm not so certain.
7. *C*: Do you know the address of *any* of the people we are going to invite?
8. *B*: I'm sure about some of them.
9. *C*: Well, this is of deadly importance. Do you actually *know* any of those addresses?
10. *B*: I dare say I do know.

Now, if at step (10) of the dialogue, *B* persists in using the term *know*, he is likely to have used more rigorous requirements of evidence than at (2). He is also likely to answer with higher definiteness of intention in relation to both relevance of evidence and gap (or difference) between evidence and the evidenced. Or, to put it more simply, he sees the need for evidence as he is made more aware of the divergence between his contentions and the evidence he has for them.

This shows that what an individual finds reasonable to require of an "I know that *p*" claim will show variation as we move along the steps of a dialogue. Moreover, any such variation might well be classified as "reasonable" since there seems no reason why we should describe standards of evidence that remain constant as reasonable or normal and take the fluctuations in particular cases as deviations from a stable norm.

Consider, for example, how three people, *A*, *B*, and *C*, might embark on the complicated project of giving a fairly large party. "Knowing where somebody lives" may, after some (normally) heated dialogue, rank high in regard to required *standard* of evidence, that is, in what *A*, *B*, and *C* accept as *adequate* evidence—higher, maybe if such a comparison could be given a more satisfactory meaning⁴ than the overworked chemist requires when asking his assistant (at the beginning of a dialogue): "Is the stuff to my right or the stuff to my left triamidotriphenylcarbinol? Do *you* know?" The everyday and the scientific are not clearly separated, nor the philosophical and the unphilosophical, as to level of requirements. Variation in stage of

development in any (normal) interaction between persons can show marked (yet normal) fluctuation in standard of evidence.

In order to avert a premature suspicion that in talking of variation in terms of increase in requirements I wish to push readers in the direction of scepticism, let me stress that at the end of a dialogue, requirements may very well drop. Suppose *C* is to be the financial supervisor of the party and that he tends to say, "I do not know the price; I shall have to check it and you must help me." If *A* and *B* discover that what *C* labels his "wild guesses" are correct to the penny, there will be recriminations: "You say you don't know, but you know very well." *C* has to bring his requirements down a step; his environment will legitimately put pressure on him in that direction. He has been overcautious and hampered the preparations for the party.⁵

Thus, either a lowering or an increase of standards may be the "normal" after certain phases of a dialogue. Instead of the "normal," however, I would prefer to talk here of the "rational," that is, of standards being decreased or increased for good practical reasons.

Maximum Requirements

It is quite natural that increases in requirements will be discussed in terms of how to *avoid* mistakes, how to *guarantee* truth, of how to eliminate *every* source of error. But, of course, all these strong terms must be taken with a grain of salt. In practice, *far-fetched* sources of error, such as earthquakes in regions where for a long time there have been none, will be frowned on as motives for changes in requirements. Although "every source" means every source, one must not be fanatical about it; one may, reluctantly or impatiently, acknowledge possibilities of error, yet dismiss them with an easy mind as of no significance.

In short, there is in everyday life always a nonconceptual frame of reference determined by practical purposes, responsibilities, and so on. A dialogue, however, may sometimes concentrate more and more on a conceptual frame, on a system of significations, and then every source may be taken in an absolute sense, that is to say, *every* source. Once this sense is given and assumed, it may then appear preposterous and ridiculous to ask for a guarantee of the elimination of every source of error, but the idea is still one that can be understood. That is, I can say, "I see what you mean, but to require

that *every* source be eliminated is of course to require the impossible. Who has ever asked for that?"

We should now take up the question of what the maximum increase of (rational) requirements of evidence would be in order to justify (not verify) "I know that *p*." But since here and in the rest of the discussion I shall assume that there is a requirement of evidence for justifiably saying "I know that *p*"—whatever the *p*—I should first of all offer some comments in support of this assumption.

In taking it for granted that if I say or think "I know that *p*," I can legitimately ask, at least myself, what the evidence is irrespective of the kind of *p* but not irrespective of the situation, I am assuming something that can be termed propositional universality, as opposed to situational universality. Ayer, Austin, and others have argued against the propositional universality of the evidence requirement, that is, against the view that evidence can be properly asked for whatever the proposition claimed to be true. But, although I shall not further substantiate my disagreement here, I think they have only succeeded in showing that for some statements—for example, about my own pain or where I live—a question of evidence is out of place in everyday life (see, e.g., Ayer 1961: 292). It is characteristic, however, that these cases are very near the limits of the useful application of "I know." Wittgenstein's remarks (1958: sec. 246) are relevant here, undermining the distinctions between "I know" and "I do not know," and between "I doubt that" and "I do not doubt that," in reference to such statements as "I am in pain." And if it is ever pertinent to say to someone else "*I know* I am in pain," it seems to be in just those cases in which others might have reasons to doubt. In what follows, I have for this reason not found it necessary to discuss occurrences of "I know" in which requirements of evidence are out of place.

Certain details in Ayer's exposition deserve closer attention here. In particular, Ayer defends the view "that there are some propositions that we can claim to know without having to know any other propositions as reasons for them." "If someone claimed to know that he was in pain or that he was daydreaming about being rich, it would seem absurd to ask him what evidence he had for believing that these things were so" (Ayer 1961: 292).

It would be absurd, perhaps, to expect *A* to put evidence at the disposal of *B* so that *B* could independently from *A* estimate the evidence *A* has at *his* disposal. For *A* to ask "Am I really daydreaming about being rich?" is

not absurd. He may have the suspicion that he is perhaps not daydreaming but making pertinent reflections: "What would I do if I doubled my income?" Or, he may on second thought find that he is or was dreaming about being a playboy—the question of money was not really touched on in the dream, he might have borrowed it. It is clear that as soon as one begins to become interested in exactly what happens and in classifying it by using certain terms, there are ample grounds for asking about evidence. If the evidence is expressed in words, propositions are formed, and whereas the dogmatist will claim them to be true, the sceptic will offer them for inspection.

In spite of his doubtful contention about the absurdity of asking (one-self) for evidence, the first quotation from Ayer, as far as I can see, expresses a tenable position. If I say "I know that p ," p may belong to a field in which I would not in everyday life form propositions in support of knowledge claims. The "How do you know?" may be left unanswered, or one may say, "Obviously I know," "I know that I know," and so on.

In certain dialogues, for example those concerning trustworthiness or introspective psychology, the status of knowledge that goes unchallenged in everyday life must be considered. The result always seems to be that insofar as the propositions state something at all, there are sources of error. Here the history regarding the psychology of degrees of intensity of attention affords an interesting field of study. This history shows that propositions that seemed to be based on the most direct, unquestionable introspection and that were made by trained observers, came to be considered doubtful and not acceptable as expressions of knowledge (cf. Spearman 1937).

To return now to the question of what would be the maximum increase of (rational) requirements of evidence in order to justify the expression "I know that p ," we can at least take it for granted at the outset that requirements may vary markedly, even in relation to a definite question, and that even in highly scientific contexts the requirements might be very low. Where would such a maximum increase land us? Would it *necessarily* prevent us from using the expression "I know that p "? Would it at least as a matter of fact prevent us from using it? In order to answer this, some preliminaries will first have to be discussed.

First of all, let us examine the basis for contending that there are definite requirements to be satisfied in order justifiably to say "I know." Perhaps the best way of bringing out the fact that there are such requirements is to

describe situations in which people are taken to task for having used the expression “I know” (and similar phrases) when allegedly they were not entitled to do so. From a variety of cases — some of which might be constructed, but agreed on by a panel of experts — one might then try to abstract rules. That is, one might try to construct more or less general requirement-hypotheses to fit the cases. (It would obviously be incautious to adopt general formulations proffered by people in concrete situations.) Such requirement formulations, with careful delimitation of intended range of validity, would not necessarily have any normative status vis-à-vis the language community, but they would at least represent attempts at clarifying and codifying the use of “I know” in terms of definite requirements.

It should be remarked, however, that it cannot be taken for granted that by increasing the number of cases surveyed, more and more definite requirements fitting the cases can be constructed. In general, there is in fact no good reason to believe in the “existence” of general regularities that would be susceptible to indefinite refinements in structure and content. In what follows, I shall speak as if one could abstract and extract requirements from surveying concrete cases of the use of “I know.” It is at least a useful fiction for purposes of exposition.

Maximum Strengthening of Requirements in the Face of Mistakes

Sometimes, even though the requirements of knowing have been satisfied, it is agreed a little later by those involved that there was, after all, a failure, a mistake. The normal thing to do, if it is important not to fail, is to take heed of the mistakes, that is, to increase the requirements covering that kind of situation in which, admittedly, a mistake was made. Then next time in such a situation I shall not claim that I know. My claim will be more modest, or I shall apply some tests such that requirements of a higher level are satisfied. Only then shall I say, “I know.”

Let us suppose that, unhappily, I make a mistake in the very same kind of situation in spite of applying the new, more severe tests. It will now be reasonable not only to increase requirements in the same kind of situation but also to increase them a little over a wider field. It is to some extent arbitrary how one is to assess the kind of situation at hand, and the consequences

it has for other situations. A decision will be made, however, and it can be described as affecting not just the old kind of situation but also a more general kind.

If we suppose that this unhappy trend goes on for some time, there are two kinds of adjustments that are of special interest: one in which requirements are always given an increase of rigorousness and in an expanding area, without covering any one specified area, and one in which eventually the use of "I know" is *in complete generality* taken to be incautious or inadvisable, other expressions being recommended in its place.

Let us inspect a hypothetical case study of how someone might have come to "know nothing":

On certain occasions I discovered that a proposition of whose truth I had been sure, and on adequate evidence, was in fact false. Having had adequate grounds for my certainty, I may be said to have been justified in claiming to know, but in fact did not know. This discovery of error in respect of a previous well-supported certainty occurred on numerous new occasions, and each time I felt greater reluctance to claim to know. Eventually, I came to lose all confidence in claiming to know, since I was never sure the evidence excluded sources of error. Because of my never being sure, I cannot now be said to know anything.

Now to what extent and in what way can such a report, biographical note, or psychological case study be relevant to the questions raised in the modern discussion on scepticism?

The actual use of "I know" among psychiatrically normal persons of a language community is at least relevant to conclusions about how requirements remain constant through time intervals, or are increased or decreased in various kinds of situations. It is difficult to see how one might legislate what would be a maximal increase beyond which one could not properly, or sincerely, refrain from using "I know." Therefore, if such an unwillingness to use "I know" became more and more widespread, we might envisage circumstances in which *knowing* became not only unfashionable but totally extinct, insofar as "I know" implies "I am convinced." Such a possibility is not to be excluded. After all, many other words have become employed more and more rarely and have tended to become extinct when occasions for their use grew sufficiently scarce; this might also become the case with "I know." As far as linguistic considerations are concerned, then, there are no objec-

tions to a process of development culminating in the extinction of the use of “I know.”

Now let us look a little more closely at the repercussions of unexpected events on standard requirements. Repercussions on standards may be said to have three dimensions: breadth, strength, and duration. Breadth measures the class of cases or situations covered. If I make a mistake in Latin grammar in spite of satisfying the standards, I may for a time increase my standards both in Latin and in other grammars, or only in Latin. Where the failure is a damaging (shameful, embarrassing) one, I may even, for a short time, show increased standards in every subject. (All within the very elastic limits of psychiatric normality.) This is the breadth dimension. If we say that the increase may be very marked or only just perceptible, we are using the dimension of strength, which is self-explanatory.

Third, if we receive no more rude shocks we simply change back to old habits and the increase in requirements gradually disappears. Here we have a time dimension, one that may be rationalized by dividing up time in terms of situations and by making use of inductive principles.

So much for the repercussions of failures. But successes and triumphs—that is, astonishing, unexpected, and important successes in “I know” situations—also have repercussions. More often than not their effect may be a relaxing one; standards drop, and inductive thinking may be the cause. As suggested by Ayer (1956: 33), if an individual has a constant flow of successes, he may be led altogether to stop searching for evidence. This, however, would tend rather to mean that “said by Mr. So-and-so” was to be taken as adequate evidence. On the other hand, successes can sometimes result in increases. For example, I may wish to retain a reputation that if *I* say I know, others may be perfectly sure that it is true.

So much for individual successes and vicissitudes. There are, of course, fluctuations in collectivities, too—in communities interacting with individual experiences. During wars and other periods of intense community life and shared experiences, the collective changes are more marked and more easily break through the individual variations. (One *should* know the enemy soldiers are cruel. Whatever the incidents that in other circumstances would certainly have repercussions, one must continue to be willing to say “I know they are cruel.”) In some kinds of situations, requirements for “I know” can drop toward zero; in others they might increase toward infinity.

Maximum and Abnormal Repercussions

We are tempted to classify some changes in standards as “irrational,” others as “rational.” Which classification we adopt depends to some extent on our system of values. In any case, there is always the possibility of constructing a set of rules from which we consider rational changes of standards to be derivable.

Suppose in giving a lesson in geometry I say that I know π to be 3.14158 . . . and later admit failure, being convinced by others that π is 3.14159. According to my (and many others’) criteria, I would behave irrationally if this prevented me from answering positively to the question whether I know that 5 multiplied by 6 is 30. It would be much too drastic a personal reaction to my failure for it to form the basis of a mistrust in my “knowledge” of the simple multiplication table; such a repercussion on standards would be unreasonable. But sometimes severe repercussions *are* reasonable. And even where they are not, the question of the use of “I know” cannot be solved by legislation according to the way rationalists would wish it to be used.

A succession of failures may cause me to refrain from using “I know” either in important matters or generally. The two cases are not as different as might be thought at first glance. If I renounce its use in important matters, I may still use it loosely.⁶ (“My wife never lets me out, you know.”—“I know?”—“Of course, I’m telling you.”) If reproved for doing this (“But you have just refused demonstratively to say *you* know what would be the right thing to do in our present predicament!”), I may point to the difference. (“Of course, you and I don’t, strictly speaking, know this about my wife. Have you lost your sense of proportion?”) When one is in a bad predicament and conscious of one’s responsibility, one finds it irresponsible to say “I know.” Thus, to refrain from using “I know” in important matters is in certain senses to give it up in general, as far as cognitive, serious purposes are concerned.

I may be considered normal psychiatrically, but still refrain from using “I know” in important matters for the rest of my life. Or I may promise myself to refrain from it, but fail; an unwillingness to say “I know” might, after all, in some situations or in some communities be as embarrassing as refraining from saying “thank you.”

To refrain from using “I know” in important matters may also express one’s awareness of *a general fallibility*. According to Austin, however, general fallibility by itself cannot be a rational motive for saying “I know noth-

ing” (in the modern sceptic’s way); there must be additional premises. If stakes are small and there are discoverable differences in the chances of a mistake, why should I *always* avoid claiming to know?

Yet, and perhaps in extension of Austin’s point, in matters of life and death, the awareness of the importance, the awareness of the terrible consequences of failure, may rationally motivate me to renounce the use of “I know,” whatever the evidence. In relation to certain subgroups of situations, therefore, “I *know* nothing” may be an adequate expression of my opinion and attitudes (Austin 1961: 65–67).⁷ As pointed out by Ayer and others, in saying I know something, I am vouching for it—thus my assertion that it has some important social implications. But then if I find it unjustifiable to vouch for (and, perhaps, to swear to) something, finding that to do so would be inconsistent with my value system, I may stick to my *personal* conviction, yet still in a rational way, and in view of conceived failures *abstain* from using “I know,” or even find it justifiable to say “I know nothing.”

Socially I perform my duty as a witness, for example, when I painstakingly describe the evidence I think I have, adding on request any further information about my personal conviction or belief, and my personal estimate of the chances of my being mistaken. The rest I leave to the jury and others concerned. If some will say that in the light of my total statement I know, or that I do not know, I will not object. *They* may say that I know even if I would not. Only if I were forced to take a stand would I give my reasons for avoiding the use of the distinction between known and not known in questions of life and death. If, on the other hand, I do employ the distinction and am sure about something, so long as certain other requirements are satisfied, I would be perfectly correct to *say* “I know that such and such.” This would continue to be so even if subsequent events proved me wrong. For then what was wrong was what I said was the case, not my saying that it was the case. It would be misleading here, too, to say that I did not know that *not* such and such if the context suggests that this implies some degree of blame: “You should have known that not such and such, but you didn’t.” The circumstances in which it is right to *say* “I know that such and such,” even if what I claim is subsequently shown to be false, are precisely those in which it would be wrong for me to say “I know that not such and such” despite the fact that this latter claim would have been true.

The most important point for us here is to make a distinction between having a piece of knowledge and having good, standard, or adequate rea-

son, evidence, or grounds for being certain. If I hesitate in, or abstain from, saying “I know it” because I see (am sure I see) a *remote possibility* of being wrong, this does not necessarily violate any explicit or implicit rules of ordinary language. It may be a symptom of overcautiousness, hypochondria, hyperactivity of the imagination, or inability to square up to some formidable responsibility, but all of this may still be within the range of psychiatric normality. My mind is not deranged; I am still a member of my language community.

Moreover I may be perfectly aware that others are much more free than I am in their use of “I know,” and disapprove of this—all *within* the framework of our common language, which is after all not the monopoly of one type of person.

One might bring out the cognitive factor separate from the use of “I know”—its rationality in terms of inductions and in terms of limitations on the fruitfulness of terminology. If there have been more failures than were expected and are tolerated within a sphere of action or investigation, it is reasonable to increase standards in order to decrease the risk of continuing a high rate of failure. No doubt some kind of inductive conceptual framework is best suited to articulate the rationality of the increase. Second, the fruitfulness of a distinction has its limitations. Sometimes the social aspect of vouching and guaranteeing is considered unnecessary. Why then use “I know”? If what I aim at is an independent evaluation of *p* by others, I modify your wording as a rational means for reaching that end. (A: But do you *know*? B: I am convinced, but *this time* you’d better see for yourself.)

“I Know Nothing”: General Linguistic Counterargument

There have been various arguments designed to rebut the claim that one can reasonably abstain from the use of “I know,” or the slightly different and stronger claim that the utterance “I know nothing” can be in order.

An argument that we certainly know at least one thing is sometimes based on a kind of linguistic *a priori*: since there is “in our language” (I should prefer “in the vocabulary of our language”) a distinction between “knowing” and “not-knowing,” there *must* be an exemplified difference between what is known and what is not known. How else could the distinction have been introduced and understood? After all, we *learn* a difference between the terms from actual instances; so if there *are* no such instances, then

we cannot learn about such a distinction. In much the same vein it has been argued that not all things can be illusory, at least some things must be veridical. Unless this were so the notion of illusoriness would lose all its point.

But surely a child could be taught to use "illusory" perfectly correctly by instances such as the difference between the neighbors' spurious Santa Claus (being only the father in disguise) and its own family's real Santa Claus, between the neighbors' naughty boy's spurious courage and his father's genuine courage? In a similar way, generation n of adults introduces the difference in terms of their (nonillusory) ideals and the (illusory) ones of generation $n-1$. The difference between "illusory" and "not illusory," as well as those between "known" and "not-known," "veridical" and "not veridical," can be introduced and learned on the basis of the beliefs or convictions of the persons concerned. Whether the beliefs are correct or not (in an absolute sense) makes no difference whatsoever.⁸

If boy A has learned to use "illusory" and "not illusory" simply by one hundred examples, and later in life he considers the cases of nonillusory things to be similar to the cases of the illusory, we may find him saying *all* things are illusory.

There is nevertheless a way in which a paradigmatic learning theory may be important in understanding rather different positions that have been termed sceptical. Thus, when writing his famous *Why Nothing Can Be Known* (*Quod nihil scitur*), Francisco Sanches (or Sánchez) cannot properly be said to have overlooked that he knew he had (or did not have) a toothache. There are several uses of "I know that p " (and related terms), and one of them relates to "matters important to the soul," such as religious, metaphysical, and scientific doctrines. This kind of use was already well established by the time of Sextus Empiricus, and Sanches, too, was certainly aware of it. Moreover, he may be said to have developed his awareness paradigmatically, seeing it applied solely in connection with doctrines, and not in connection with utterances such as "I have a toothache." But then by applying the known versus not-known distinction within the sphere of that particular use, Sanches neither had nor did not have a toothache, insofar as neither the assertion that one has nor the assertion that one does not have a toothache constitutes a doctrine.

The point of this example is that the terms *sceptic*, *sceptical*, and *scepticism* have been applied for a very long time, and they are closely connected with uses of "knowing" that may very well not be the first uses one learns as

a child. Nevertheless, such uses of “knowing” are learned somehow. A debate on scepticism might certainly refer only to “knowing” on the infantile level, but it ought to be clear that this does not cover all interesting uses of “knowing” and especially not those important in philosophical literature.

Circularity of the Sceptic’s Argument

There is another shortcut aimed at avoiding scepticism: It is claimed that the utterance “I do not know anything” is absurd or inconsistent because I implicitly assert that I know that I do not know anything. But this anti-sceptical argument is untenable. It rests on the false assumption that the ways of announcing “I do not know anything” can be reduced to one, namely, “I know that,” or to some others from which “I know that” can be derived. There are, however, a number of ways of announcing that do not fulfill this requirement, for example, “I am perfectly convinced that” or “I believe that.” Sextus Empiricus can be studied with profit on this point.

Let us now turn to the utterance that we are presuming to be made in complete seriousness, “I cannot get to know anything.” Against its tenability, considered as a statement, there are strong arguments of various kinds. Let us first consider those arguments that claim the existence of conclusive, unretractable, and irrevocable evidence.

The Conclusiveness of Conclusive Evidence: Social and Linguistic Rightness and Truth

In philosophical debate there are still symptoms of a confusion between the right to say something—for example, the right to say “It is true that *p*,” “There can be no doubt that *p*,” “Of course, *p*,” or “In this I cannot possibly be mistaken”—and the certainty that *p* is true. If “I know that *p*” is interpreted in this confused way, the statement may be thought to be unretractable if in fact I had the right to say it and whether or not *p* is later considered false. Let the relevant distinctions be repeated once more.

To assert “I have conclusive (unretractable, irrevocable, decisive) evidence” or “This closes the matter once and for all” or “Here no doubt is possible” or “It cannot conceivably be otherwise” or “This is absolutely certain,” is justified in everyday life if certain requirements are fulfilled. In the

course of a dialogue standards may vary, just as in the case of “I know.” Unexpected kinds of failures and successes can occur, and they have repercussions of various kinds. Here is a little dialogue for illustration:

- A: The two papers *are* in this room.
B: That is simply inconceivable. I have searched for them all day in this very room. It is absolutely impossible that they are here. I know they are not here. The evidence is utterly conclusive.
A: Well, look here, then. Here is one of them.
B: So it is. I don’t understand this.
A: Should we look for the other?
B: Well, yes, we’d better do that.
A: It is not inconceivable that the other is here?
B: Hmm.

If *B* had searched the room all day, one would allow that he was entitled to use expressions like “absolutely impossible,” “perfectly certain,” and “utterly conclusive.” However, there is not the slightest guarantee that he would not have to retract. The justifiability of exclaiming “conclusive!” does not exclude having made a mistake. Douglas Arner (1959) stresses that in the face of conclusive evidence, any further demand for evidence is unintelligible:

It is quite true that grounds treated as conclusive are always short of a demonstration and even occasionally prove inadequate. The important thing is that conclusive evidence *concludes*: no demand for more evidence in the face of conclusive evidence is intelligible. (Arner 1959: 88)

If Arner could only tell us what conclusive evidence looks like so that we could infallibly recognize it and avoid talking unintelligibly! But his attention soon shifts to what *counts* as conclusive:

What counts as conclusive evidence is a matter of tacit, continuing agreement among the users of the language. We learn early that we are not to claim knowledge unless we have met certain requirements in the way of qualifications and evidence. These requirements are founded chiefly on what grounds have proved adequate almost all of the time. . . . (Ibid.)

Here there seems to be no distinction made between “The evidence for p is conclusive” and “The evidence for p satisfies what counts as conclusive evidence.”⁹ The latter may be true despite the falsity of the former, that is, if “conclusive evidence” is taken to imply truth, and I think it does for most interpretations. “I have conclusive evidence for p , but p may be false” does not work.

On the most primitive everyday level, there is perhaps a good deal of tacit agreement about what counts as conclusive evidence, but it certainly seems more appropriate to reserve the conceptual distinction between conclusive and nonconclusive evidence for when there are explicit premises and conclusions. The distinction seems to belong to that level of talk. And at that level, one is aware of the difference between having the justification for *calling* some evidence “conclusive” and conclusive evidence itself. Here, as with knowing, I may be perfectly correct in saying something, but completely wrong in what I say. What counts as conclusive evidence that a person is dead is, for obvious reasons, rather strong evidence among responsible physicians, but once in a million or more cases a frightful mistake is discovered. Some people, of course, will find these cases uninteresting because for all practical, normal, ordinary, everyday purposes they just do not occur, but others will find them extremely interesting.

“This evidence is (already) conclusive. May I, please, have some more?” This would be a rather original demand, but at least to me perfectly intelligible. For there may be people who make the mistake of not taking the evidence to be conclusive, and they may want me to be able to add some pieces, some additional witnesses, and so on. “This evidence must count as (can safely be treated as) conclusive. But may I, please, have some more?” This kind of question is not only intelligible, but to pose it may sometimes be a duty. There are no definite requirements of conclusiveness; they vary in relation to a number of factors (responsibilities, consequences of failure, past experience within a narrow field to which p belongs, past experience in a broader field, etc.).

The inadequacy of the everyday and the normality arguments for establishing what is conclusive evidence is well illustrated if one considers utterances such as “We are never justified in being absolutely certain” or “I do not know anything whatsoever” or “Nothing *can* be known.” We just have to reflect that there are, on the one hand, requirements for being justi-

fied in saying such things (try it out at some parties!) and, on the other, *admitted* failures; that is, those engaged may, after some time, retract and say “I *do* know something, after all.” Nor is the requirement for announcing “failure” universally higher than that for announcing “success”; that is, it is always equally possible that some failures may turn into successes.

I think we can safely say that sceptical locutions in everyday life are not intended to cover, systematically and in relation to current conceptual frameworks, an assertion “I do not know anything.” Compared with their epistemologically intended counterparts, such everyday locutions are offhand and unsystematic verbal gestures. And even if they are subjected to some form of regulation in the shape of justifiability requirements, these latter are of a fairly indeterminate and unconceptualized sort. Instead of everyday utterances, therefore, we shall take up sentences such as “I do not know anything” as they appear to be placed in philosophical debates, in the wide sense of “debate”—that is, in discussions that intend such sentences in a more systematic and conceptualized way than that in which they are used in everyday life.

Examples of Things We Know or Can Know

Epistemologists have provided us with many good examples of the kinds of things we know or can know. The method by which they are introduced goes more or less as follows. First, a certain situation is described, and then in that situation we are to suppose an utterance of the expression “I know” (or something equivalent). Then the author of the example, sometimes after adding in some convincing details, appeals to the reader, as much as to say, “Now you see, you doubting Thomases! Repent!” But of course, if the examples are to have their proper force in a debate, the adversary must not be thus pushed or terrorized into accepting them. One particular method of persuasion, astonishingly common all the way from Plato to Austin, amounts to little more than saying something like, “Suppose I see an elephant and I say ‘I see an elephant,’ could I be wrong? Would I ever have to retract?”

The procedure is intended to convince us that there are frequent and indisputable cases of our knowing that things are what they are, or as they are. Austin (1962: 115), for example, asserts that some statements “are *in fact* incorrigible” (Austin’s italics). They are “quite certainly, definitely, and un-

retractably true" (Austin 1962: 115). And, implicitly, he takes this to amount to a proof that there are p 's such that I know that p .

Thus, "If I watch for some time an animal a few feet in front of me, in a good light, if I prod it perhaps, sniff, and take note of the noises it makes, I may say 'That's a pig.'" This statement "will be 'incurrigible', nothing could be produced that would show that I had made a mistake" (Austin 1962: 114). Here Austin will have us assume, entirely on his own authority, that he *is* watching for some time, that it *is* an animal he is watching, that the light *is* good enough for the purposes at hand, and that he *is* sniffing the animal in question. By being made to postulate the truth of so many premises, we become confused as to how the conclusion could possibly be false. But of course we should recall that an implication comprising a conjunction of a swarm of antecedents and only one consequent is among the very weakest that can be made.

It may be conceded that Austin, under most circumstances in which this could have happened, would be perfectly justified in saying what he said in the example. But it is hard to accept that "nothing could be produced that would show that I had made a mistake." Very much depends on one's acquaintances, whether they have a penchant toward practical jokes or include an amateur magician. (If we are asked about pigs with a professional magician nearby, we are wise to bet only a small amount and keep our "knowing" under strict control.) In short, even a good amateur magician could bring us into a situation such as the one Austin describes and provoke us into saying, "I know this is a pig" and soon after make us *retract*.

There is something to be said in general about examples that contain plenty of detail about what has already been done in order to ensure that p actually *is* the case. The doubter or disbeliever is, as it were, politely but authoritatively requested to accept all the details as true of the situation in which "I know that p " was uttered. He has then nothing to complain about. But it is easy to forget that if the example were true to life, the doubter should have had the opportunity to inspect the details for himself; he would not have to rely on hearsay.

Consider in this respect the many reports of ghosts, for example, which *if* the apparently true details concerning the situations are accepted, are overwhelmingly convincing. The contemporary ghost-hunter, however, has professional rules that make him for the most part withhold judgment until he has the opportunity to report about the situation himself.

Consider another example: Someone remarks in casual conversation, “As a matter of fact I live in Oxford.” According to Austin, the speaker “knows it to be true (or, if he is lying, false)” (ibid., pp. 117–18). But many people are in trouble because they *want* to be able to say truthfully “I live in such and such town (city)” —because an authority of some sort can otherwise deprive them of certain privileges—but they are uncertain. The criteria are complicated, and their satisfaction is not always clear. Incidentally, Agrippa of Nettesheim, a famous, rather unruly and restless “sceptic” in the history of modern philosophy and author of *Of the Uncertainty and Vanity of the Arts and Sciences* (*De incertitudine et vanitate de scientiarum et artium*), could probably only rarely give an account of where he lived if he could have been said to live in any definite place at all. J. Wasiutyński (1963: 130) has assured us, however, that there “can no longer be any doubt that we live in a spiral nebula.” So, is no one to worry any more about where he or she lives?

The gist of the matter seems to be this: We take “I live in Oxford” to be beyond any doubt and requiring no evidence because we place ourselves in a particular situation in which we have no *reason* or *incentive* to doubt. But the claim that I live in Oxford is not made more certain by being expressed in a situation in which the reasons and incentives to doubt its truth are reduced. To say that it was, would be to misunderstand the relation between a statement and the conditions in which it is made. The conditions are not to be seen as part of the claim and therefore cannot be taken to determine whether or not it has the property of “being certain.” A claim made in one situation that excludes reasons and incentives to doubt its truth can be made in different conditions in which such reasons and incentives once more come into play.

Consider how in casual conversation the requirement of evidence for “I know that *p*” may be so small as to make the claim to know well-nigh gratuitous; whereas in criminal cases, for example, the requirement for evidence must be adduced. The difference here is largely one in the requirements of justification and as such is strictly related to questions of responsibility that may be near zero in casual conversation and “infinite” for an eyewitness in a murder case.

A final example:

If I carefully scrutinize some patch of colour in my visual field, take careful note of it, know English well, and pay scrupulous attention to just what I’m

saying, I may say "It seems to me now as if I were seeing something pink"; and nothing whatever could be produced as showing that I had made a mistake.
(Austin 1962: 114)

That Austin, after all his care and effort, his attention to exactly what he is saying, still uses the term *seems* suggests immediately something rather suspicious here, as does the use of *as if I were*. There is, in short, ample indication that something could well happen to make us assume he had made a mistake. Or so Austin's words suggest. If, on the other hand, the situation (as he judged it) warranted perfect certainty, then what he in fact uttered is grossly misleading. Surely it would have been more correct for him to avoid the hedging forms of expression and say, "I am seeing something pink."

I shall not try to introduce anything new into the difficult contemporary discussion on certainty and knowledge within the field of immediate perception. Austin has himself suggested many sources of error and therefore of possible retractions. The crux of the matter can be put in this way: A proof or strong argument in favor of *incorrigibility*, *unretractability*, and related *-bilities* must be more than an inductively based prediction. It should somehow derive from contemplation both of the nature of the incorrigible statement and of the subject covered by such a statement. This, however, is very hard to achieve. In fact, Austin himself points out how difficult it is to delimit certain *kinds* of statements as incorrigible by virtue of their subject matter (e.g., sense data) or other characteristics.

It seems, therefore, that incorrigibility claims are essentially based on convictions that in the particular case there could not be any source of error, both in the usual sense of "source of error *worth mentioning*" and in the sense of no source of error even of the more remote kinds that we neglect in daily life. This conviction is based on a trust that one's imagination works as it should at the time of making up one's mind about the corrigibility when one is "looking" for sources of error. So incorrigibility theses are testable by future events; they are vulnerable. Simply to add to one's statement "And what I have just said is incorrigible" does not close the matter.

Let us look at the discussion on incorrigibility dialectically. Strings of striking cognitive successes of incorrigibility claims may justifiably influence the standards for incorrigibility or unretractability claims, making them less rigorous. On the other hand, series of striking cognitive malfunctions may justifiably influence standards by making them appreciably rig-

orous. What is remarkable here is the “feedback mechanism”—the inherent norms, mores, and institutions affecting changes in certain directions.

Just how far can the changes of standard bring us? In fact, there seem to be no limits; they can be lowered or increased indefinitely in the sense that, having reached a certain height or depth, there will always be the possibility of an additional increase or decrease.

A criticism of contemporary debate on (epistemological) scepticism is that it does not seem to take into account the dynamics of standard fluctuations. But fluctuations affect the application of all so-called closure-expressions, such as “conclusive evidence,” “in corrigible statement,” “indubitable utterance,” and “definite establishment of truth.”

If the fluctuations are taken to result from the operation of some kind of factors—if, in terms of methodology, they are taken to be the dependent variable—what are the independent variables? One might be inclined to say that it is our experience that affects the standards and determines the fluctuations. This suggests a kind of empiricism à la John Stuart Mill in which whatever affects us, hence also our raising and lowering of standards, is something in our experience. However, such a way of putting it would be misleading because we are ourselves in some sense interposed between the happenings and the “resulting” fluctuations. There is a factor of making, supporting, and applying rules or mores that cannot be accounted for as long as we use a model of causation, of happenings *causing* fluctuations.

However, it is not our aim here to find out why or even how fluctuations operate. It suffices to notice that if the dynamics of fluctuations are not explicitly taken into account, one and the same statement may justifiably occasion opposite estimations as regards incorrigibility, unretractability, and unquestionableness. The situation in which the statement is supposed to occur is, in such cases, placed as a member of different series of situations. If it is taken as following on a long series of cognitive failures, a verdict of “corrigible” may be adequate, but if it is taken as following an opposite series, the adequate verdict could be “in corrigible.” As long as they are not explicitly related to the series, the verdicts are mutually inconsistent. But, of course, once that is done, they are compatible.

Recent discussions concerning examples of conclusive evidence and incorrigible statements support the simple prediction that the participants aiming at undermining the examples will always find (practical, particular) sources of error (if the examples are not circular), and that the participants

aiming at saving at least one example will be able to introduce modifications so as to eliminate those (particular, practical) sources. In fact, Sextus Empiricus's maxim "Not more than" seems eminently suited to the debate: the arguments for incorrigibility are not decisively stronger than the arguments against. A general conclusion unrelated to the dynamics of standard fluctuations, to the effect that there *are* cases of conclusive evidence, seems equally unconvincing as one to the effect that there are not.

Examples of Evidence Fusing with the Evidenced

"Why on earth should one think that such verification can't ever be conclusive?" It is Austin (1962: 118) asking the question, and his theme is statements in need of verification.¹⁰

If, for instance, you tell me there's a telephone in the next room, and (feeling mistrustful) I decide to verify this . . . I can take it to pieces a bit and find out, or actually use it for ringing somebody up—and perhaps get them to ring me up too, just to make sure. (Ibid.)

The object has then "stood up to imply enough tests to establish that it really is a telephone; and it isn't just that, for everyday or practical or ordinary purposes, enough is *as good as* a telephone; what meets all these tests just *is* a telephone, no doubt about it" (ibid., p. 119). Or, to extract the principle, something's membership in a class of things is for all *practical purposes* conclusively established if results are positive when the thing is subjected to a finite battery of tests.

But, alas, do we, when trying to verify concrete examples, test the identity of a thing as to what it is for everyday, practical, or ordinary purposes? If we sometimes have other (legitimate or illegitimate) purposes, and the thing then has to be classed differently, it may turn out that those other nonpractical or unordinary or uneveryday purposes are relevant.

Let us nevertheless leave that point and consider whether a case can be closed after a finite series of tests have been performed. In the case of the telephone, I have no concrete objection; positive results from the four tests would be, I am perfectly convinced, enough for me to exclaim, "Then this *is* a telephone!" because nothing but telephones, and only telephones, satisfy the four tests as far as I can see.

But what if the question of a telephone in the next room emerged during a police search? We are still only interested in situations in which maximum requirements are made. David Krueger, one of the greatest impostors of all time, and many lesser crooks have had telephones (“real” ones?) installed that buzz at convenient intervals during crucial conferences. The voices of very important people are heard over the phone, and some impressive business is cleared up; the voices, however, are from a gramophone or tape recorder. In the spying profession, innocent instruments such as telephones are completely rebuilt in order to make less innocent instruments. They still at least look like telephones. The instruments must perhaps satisfy all of Austin’s four telephone requirements or, more correctly, must be such that a suspicious person will normally come to that conclusion after a thorough search. In short, the four requirements (in part seemingly, in part really) being satisfied, the thing may still be a lot of things other than or besides a telephone.

But enough of this. The real point of the example is to show that the idea of a finite battery of tests for identification purposes brings in no radically new factors. Especially when the tests have to be performed one at a time, as is the case in the telephone story, it is always possible for new sources of error to develop with time. Thus, our ultimate view will be unaffected by this story, but we do not suggest that the discussion over (concrete) examples is likely to come to an end.

Incorrigibility and Fallibility

An essential characteristic of human fallibility is the unpredictableness of what kind of mistake will be next. If it were true that human fallibility had (a) infallibly ascertainable limits that (b) were infallibly identifiable in certain particular cases, there would be human fallibility in one sphere and human infallibility in another.¹¹ But the awkwardness of the human predicament is due precisely to the unpredictable failures. However long the series of successes and however well the field of these successes can be delimited, this trait of general human fallibility does not change.

Let us for a moment grant that such is our human situation and consider some of the consequences. Does this situation make it universally justifiable, and in fact true, to add that “I may be wrong”? If so, it will always

be justified and true when I have already said "I know that p ," to add "but I may be wrong." But this disqualifies my utterance "I know that p ," and the only thing to do will be to give up ever using "I know" and to answer, being prodded, "I do not *know* whether p is true or false" and "I do not know and cannot know anything."

Here, then, is a possibility of deriving modern scepticism from a doctrine of general fallibility. But there is weakness both in that doctrine and in the derivation of scepticism from it. If we ask "Is the doctrine of general fallibility intended to apply to itself?" a positive answer at least opens the door to allegations that human beings might, after all, be pretty infallible, which again makes the doctrine useless for deriving "but I may be wrong" as a general addition to "I know that p ." A negative answer, on the other hand, provides us with an instance of a statement that is incorrigible and true; in that case "I may be wrong" is false if this statement is inserted for p . The derivation, therefore, collapses, at least in its completely general form.

More important are the considerations adduced by Austin.¹² Human fallibility involves fallibility in keeping promises and in many other important social transactions. Why does this not prevent us, and why *should* it not prevent us, from promising? Austin stresses that there must be special reasons for suspecting a break of promise in order to make it rational to avoid promising (because of fallibility). Similarly with knowing: Only where there is something special that points to an important source of error should fallibility prevent me from using "I know." General fallibility may be generally admitted, but not fallibility in any definite concrete case. That is, general fallibility is not permitted to constitute a justification for comprehensively avoiding "I know":

A: Tell the judge you know that it was he who did it.

B: What a responsibility to take! And do I *really* know? I am but a fallible human being.

A: That holds for all of us. Go on, tell him, you coward.¹³

In all concrete cases in which there involves a social responsibility to say "I know," general fallibility cannot be invoked. The same holds for all cases in which the sentence "I do *not* know" is conceptualized¹⁴ within a framework such that it implies awareness of how to know that one does not

know, awareness of how to get adequate evidence, and of what kind of evidence is lacking. Here, too, general fallibility cannot count as an adequate argument in favor of the exclusion of knowledge.

Nevertheless, a dialogue starting in the midst of everyday concerns may reach stages at which general fallibility becomes relevant in the argument. This we will discuss later.

Corrigibility as a Requirement of Scientific Knowledge

Although a justified utterance of “I know that p ” is not incompatible with the general possibility of error, it is, as we noted, inconsistent with a concomitantly uttered “I may be wrong.” What then is the core of a reasonable and workable incorrigibility requirement of knowledge? It can be stated in very few words.¹⁵

One cannot say “I know it, but I may be wrong”; “I know that p , but there is a chance that p is false”; “I know that p , but some time ago I knew that not- p ”; and “I know that p , but next year maybe I’ll know that not- p .” That is, if I have said “I know that p ,” and later I am convinced of not- p , or feel uncertain about p ’s truth, I shall have to retract. I shall have to admit “I *do not* and *did not ever* know p .”

The nature of the requirement of incorrigibility can be further clarified by discussing its relation to statements made about scientific knowledge. This knowledge is said to be essentially corrigible, liable to revision, approximate, never absolutely certain, more or less uncertain, never more than probable, the best we have but imperfect, always containing errors, often partially or totally modified, and sometimes swept away during scientific revolutions. Often these things are also predicated of “human knowledge” in general. But what then of our incorrigibility requirement?

Let us first notice that these characterizations nearly always refer to scientific knowledge *in general* or large bodies of doctrines, theories, hypotheses, and so on, taken together. Very rarely do they refer to single statements, or to single definite occurrences of “I know” uttered by a scientist.

If we glance at histories of science, or at historical accounts of theories, such as atomic views about matter, we find ample reference to the knowledge of the times—including doctrines that have subsequently been revised or completely abandoned. But we discover no (or practically no) kinds

of statements inconsistent with the “prohibited” locutions listed at the head of this section or, rather, with their equivalent third-person locutions. For instance, we do not find “Descartes knew that p , but already Newton knew that not- p ”; “He knew p , whereas we now know not- p ”; and so on.

We do find, on the other hand, that certain knowledge was corrected or improved on, but still “in the abstract”—the term *knowledge* being used, not the verb, and with no recourse to particular statements. There is thus no direct contradiction between the corrigibility view of knowledge especially common in reference to science, and the incorrigibility requirement for “I know that p .” Perhaps, in view of the tendency to use the noun *knowledge* in the former case and the verb *know* in the latter, it might be wise to talk about the “incorrigibility requirement of *knowing*,” and the “corrigible and fallible nature of scientific *knowledge*.”

Only persons can know. Yet concepts of knowledge can be, and have been, construed in such a way that knowledge is impersonal. Knowledge can be stored away in libraries, whereas knowing cannot. If knowledge can be transferred to books and put on tape, the existence of knowing readers and listeners can, of course, no longer be guaranteed by the existence of knowledge.

Thus, the distinction between knowing and knowledge can be of *some* help in avoiding certain pitfalls when contemplating fallibility and incorrigibility. The distinction is, however, not clear enough or simple enough in actual use to be of decisive value. If I say “I know that p ,” it is perfectly proper and legitimate to take this to imply that I have a piece of knowledge, namely that p . But this piece of knowledge must be true, that is, partake of the incorrigibility of truth. Again, if I tend to use “I know” repeatedly during conferences or lectures or refer to large groups of statements saying “All this I know,” there will be whole bodies of claimed knowledge for which the incorrigibility requirement is normally claimed to be satisfied. Thus knowledge claims may sometimes imply an incorrigibility claim even when they refer to a whole body of doctrines or statements. Appeal to usage, then, has only limited value.

Perhaps some of the uneasiness we sometimes experience when advocating the incorrigibility requirement for “I know” stems from a faint association with a preposterous infallibility claim for scientific (or other) knowledge: the claim that the body of science, an encyclopedia of scientific knowledge, is such that no error can or will be found and corrected.

Can the Incorrīgibility Requirement Ever Be Satisfied?

Accepting the idea that knowing involves an incorrīgibility requirement—which can be partly expressed by saying “I know, but I may be wrong” is an improper expression—the question then arises, If I require incorrīgibility for the proper use of “I know” and yet refuse to apply as standards of incorrīgibility standards of evidence that socially and normally justify my saying “I know,” what do I take incorrīgibility to consist of? How does one conceive an incorrīgible statement as distinct from statements, say, with few and remote sources of error?

So far as I can judge, there are no criteria by which we can make the distinction, at least none that would guarantee correct results.¹⁶ Remember that standards allowing any sources of error whatsoever would have to be rejected. But, then, if incorrīgibility is (practically) inconceivable in every concrete case, we have to ask ourselves whether the requirement is *unwarranted*. Since it is impossible to satisfy, surely this requirement functions no differently from any other requirement that makes “I know” useless, that is, that prevents any correct use or occurrences of “I know” whatsoever. Could we not, for example, just as well require that *p*, in “I know that *p*,” be green, square, and smell of jasmine? The effect would be the same—or perhaps better insofar as we would not lead innocent people, with little ability to see sources of error, into misusing the phrase “I know.”

The relevance and strength of these reflections can be assessed more clearly if we first ask, in a preliminary way, where we are in the dialogue, what stage we have reached. It seems that we are not here considering something that implies criticism of uses of “I know” satisfying normal, social standards. We have already concluded that all such standards sometimes break down, or at least are liable to break down. We have in fact branched off from the usual discussions in concrete cases in which mistakes are supposed to be detected and standards modified, and have entered into a study and discussion of the implications of the view that the expression “I know, but I may be wrong” is improper. In fact, we are now taking a broad view that comprehends both the experience of past mistakes and the implications of the impropriety of the expression “I know, but I may be wrong.”

The transition to this viewpoint is effected in the light of the history of supposed mistakes. This is, of course, an undertaking and a purpose *dif-*

ferent from the usual, normal, or everyday. What we are interested in may be stated in various ways, one of them thus: errors, for instance, in geometry and in the historical development of the calculus of probability, have cropped up in a completely unpredicted way; judgments proclaiming that an error has been found have in some cases been retracted; in other cases such judgments continue to be upheld. For example, in this century, a large-scale reversal of judgments has affected Stoic logic. Because it was interpreted by Karl von Prantl and others in the light of Aristotle, we now say that Stoic logic was misjudged. Consider, too, the case of Aristotelian physics. Here there has been a shift (broadly speaking) from acceptance of it as true to a vehement rejection of it as false, and then a shift toward a kind of relativism, according to which if certain modern postulates and definitions are accepted, then there are many plain falsehoods, but if Aristotle's own are used, there are less.¹⁷ More often than oscillation from true to false and from false to true, painstaking studies reveal incomparabilities. Sentence T_0 is given various interpretations T_1, T_2, \dots . One generation accepts T_0 in the sense of T_1 ; another rejects T_0 in the sense of T_2 . How the first generation would react to T_2 and the second to T_1 is not known. The sources of incomparability are as unpredictable as those of error and affect the use of "I know that p " just as heavily.

It is my impression that in the course of intense studies of reversals of judgments interculturally and down the centuries, the application of the known/not-known distinction becomes unwise. That is, the use of this distinction in daily life does not itself furnish acceptable grounds for saying in such contexts "I know" in some cases and "I do not know" in others. Besides that, the usual incentives for saying such things disappear. Let us see how this might be.

Starting with everyday-life situations, one may in a perfectly natural way be led to discuss reversals of judgment in general, and from that to reversals of judgment in systematic research. What, at this stage, would be the reasons for applying the phrases "I know" and "I do not know"?

One could begin to apply some normal standards for "I know" and "I do not know" that appear in historical narrative or elsewhere. Any specialist on human failures must himself claim to satisfy such loose standards. But what if someone questions him as a fellow student at the same stage of the debate?

Well, first of all, we note that “I know” has a performative function conjoined with the cognitive, and this function is, as we have seen, inessential, irrelevant, or even disturbing in research communication. One researcher does not *vouch* for a (research) statement that the other then makes use of on the basis of trust. In fact, the situation could easily become ridiculous if the fellow student insisted on using “I know” or “I do not know.” In short, there is less incentive here for using “I know that *p*” at the stage of discussion we are now considering.

Second, even if there were an incentive, how could the conceptual framework erected during the debate be pressed to yield a basis for the use of “I know”? Such a basis is destroyed by concentration on the truth requirement, by the resulting explication of the incorrigibility requirement, and by the detection of sources of error.

Perhaps it will be objected that this latter is a “mere” psychological account of inapplicability. But whatever the suggested demerits of this, the facts still provide the basis of a rational reconstruction. It is possible to construct rules for reasonable limits of the distinction’s application under variation of definiteness of intention, or to develop framework rules, the changes of framework being in turn correlated to stages of a dialogue.

We have raised the question “Can the incorrigibility requirement ever be satisfied?,” and the answer proposed is no, but with an essential qualification. The question belongs to the stage of a dialogue at which the standard requirements for justifiably denying “I may be wrong” are out of place, that is, the stage at which the rules regulating the propriety of the opposition of “I know” and “it cannot be wrong” are no longer applicable. In their place there is an unsatisfiable requirement that there should be no sources of error. This requirement is not unsatisfiable because it is unintelligible or nonsensical or because it can be derived from some kind of logical or other necessity. The basis for stating “It cannot be satisfied,” in my own case at least, is a study of proposed examples of incorrigible statements. How this basis is to be classified methodologically, I must leave for others to decide.

There is another qualification. There are good reasons—though not, I think, decisive ones—for demanding a description of particular sources of error in criticizing a proposed incorrigible statement. In this view, the claim for a statement’s incorrigibility holds so long as no particular source of error is given. However, in many cases and especially in relation to negative

examples ("I am *not* using the tail of a scorpion as a pen in writing this sentence," and the like) the sources will be ridiculously inadequate as *particular* sources of error. Perseverance in claiming corrigibility will then probably be found in some abstract considerations about sources of error; for instance, the chasm between evidence and the evidenced or the general fallibility in human thinking. I say probably, because here it is a difficult question of motivation. So, if it is agreed that *particular, special* sources of error are to be enumerated for corrigibility to be substantiated, my conclusion would have to be that there *are* incorrigible statements but that they are of very special kinds, occurring neither in everyday life nor in science, but constructed for the very purpose of establishing the thesis that there are incorrigible statements.

It will be pointed out, however, that if incorrigibility cannot be realized, a requirement of incorrigibility will amount to a demand for the impossible. But can we rationally demand something impossible? It seems not. Then if it is irrational to demand the impossible, to require incorrigibility is a case of irrationality. It might therefore be concluded that scepticism is irrational because conclusions such as "We cannot know anything" will have at least one premise that is irrational; and because we are aiming at being rational, the conclusions will have to be rejected.

What are we to make of this argument? Well, it seems clear that it would be of value only to an opponent who does *not* require incorrigibility, who is satisfied with what he *can* attain. For one could scarcely accuse the sceptic of irrationality unless one could show that there was a rational alternative in which incorrigibility was not required. Otherwise one would surely have to concede the sceptic his argument rather than criticize it.

However, it is not entirely accurate to say that the sceptic himself is demanding the impossible. All he states is that those who insist on using "I know that *p*," and who also require incorrigibility as a requirement of the known, demand the impossible. At the same time he would contend that a clear-cut explicit renunciation of incorrigibility leads to contradictions or to intolerable divergences from the established usage of "I know that *p*," an argument that we have tried to substantiate in the previous chapter.

Arthur Pap (1949) summarizes his own and George E. Moore's antisceptical position in a few words. The *real existence* of the external world is established roughly as follows: I hold up my right hand; I see it, you see it, hence my right hand really exists; hence the external world really exists. But the

Pyrrhonist would quite happily participate in a discussion, say, about whether this or that war veteran has a right hand or not. He is not a particularly diffident or mistrustful sort of person and might even believe and trust the testimony of others without seeing the man in question. But the words *real existence* is commonly associated with technical philosophic terminologies. It is here that the Pyrrhonist's suspension of judgment enters the picture. Given professional definitions of *real existence*, *hand*, *my*, *see*, *hence*, *world*, and so on, the Pyrrhonist is one who is likely to find himself unable to find one professional opinion more convincing than another. Pap adds:

The question which the skeptic ought to be able to answer is: *what would it be like* to know for certain that the objects we perceive really exist, in other words, what do you, skeptic, *mean* by the phrase "I know for certain that *x* really exists?" That you cannot be using the phrase the way common sense uses it is evident from the fact that your disagreement with common sense is not a *factual* one, i.e. one that could in principle be settled by making further observations. No matter how many corroborating tests we may adduce as proof for the real existence of our hands, the skeptic still is not convinced. (Pap 1949: 147–48)

In his answer, the sceptic would stress that he listens to dogmatists in order to understand the statement "I know for certain that *x* really exists." Surveying the various conceptualizations offered, however, there has not as yet been any *x* such that he, the sceptic, finds it certain and true that *x* really exists. But this does not preclude the sceptic from exhibiting trust and confidence in his or anyone else's having two hands, and it will be up to the dogmatist to prove that trust and confidence imply adherence to a conceptualization concerning the real existence of an external world.

Pap attempts, he says, "to show that the proposition, doubted by the Cartesian skeptic, 'there exists an external world[.]' can be known with certainty by observing the way words are commonly used." His argument runs as follows:

Hence only one conclusion can be drawn: the skeptic must use the phrase "Knowing for certain that *x* really exists" in some very special sense, and as long as he does not explain what that sense is, we may as well assume that the statement "we can never know for certain that any physical objects really exist and are not mere dream images" is either false or else meaningless. (Ibid., p. 148)

If a man remains unconvinced after inspecting a long list of arguments in favor of the real existence of an external world *in the sense (or senses) of*

Cartesian dualism, to my mind he deserves to be congratulated. But to conclude that the sceptic must use the phrase “knowing for certain that x really exists” in some very special sense is wholly gratuitous. Indeed, in elaborating Cartesian concepts of real existence and the external world, one obtains very special senses, high-degree precizations of everyday terms, many of them transintentional in relation even to most professional epistemologists. The sceptic’s position in respect of these is that he is faced with alternative directions of precization and he sees no convincing argument why he should choose any one of them. As for the appeal to ordinary usage, that is beside the point; here the sceptic is entitled to insist on the unwarrantedness of applying any clear-cut conceptualized distinction between knowing and not-knowing.

It seems that Pap disregards the long and difficult path from believing somebody has a right hand, and has not lost it, to asserting propositions, positive or negative, concerning the real existence of something. Otherwise he would not be so optimistic as to try to show, by noting the way in which words are commonly used, that the Cartesian dogmatist (as an opponent of the Cartesian sceptic) is correct.

In short, it seems that the sceptic’s position is in no way affected by the unsatisfiability of the incorrigibility requirement. On the other hand, it must be remembered that when we talk in terms of incorrigibility, we are applying the known/not-known distinction at a stage in the dialogue at which the conclusion that incorrigibility is impossible no longer implies criticism of uses of “I know” satisfying normal, social standards. As far as these latter issues are concerned, this whole question of whether incorrigibility is possible or not does not arise. The relation here between ordinary uses of the distinction and uses in the extended stages of the dialogue can be aptly described in terms of Charlie Dunbar Broad’s (1925: 5) definition of a “silly theory”: “By a ‘silly’ theory I mean one which may be held at the time when one is talking or writing professionally, but which only an inmate of a lunatic asylum would think of carrying into daily life.” The incorrigibility formulations and formulations like “I do not know anything,” which can be accepted as expressing tenable conclusions provided certain qualifications are also accepted, have by these very qualifications an intended field of validity that explicitly *excludes* daily life. They cannot be carried over for the simple reason that if they were, they would not be the same conclusions.

The Incorrigibility of Truth

We must include here a few words on the role of the notion of truth in creating disturbing problems about knowing. The requirement that in order for me to know that p , p must be true, creates complications because the sense of “true” here is a very demanding one. In order that I should know that p , p must be the case. The notion of a true statement implied here is well defined by Aristotle (especially if *esti* is translated as “is the case”): true statements are statements that say about that which is the case that it is the case; false are those that say about that which is not the case that it is the case.

If it is the case that p , it cannot also be the case that not- p . The exclusiveness, the narrow path of truth, is also well taken care of when, following Aristotle, we link the notion of truth to his (so-called) principle of contradiction.

In ordinary, undisturbed discourse and thinking, there is a seemingly stable insight into what is the case. Even in posing questions and doubting (about something definite), there are always some stable insights implied, some indubitable and direct access to what is the case. By requiring “ p must be the case,” “what is the case” (*der Sachverhalt*) becomes unrelated to our standards of evidence, our purposes of discussion, our standards of incorrigibility. Yet the notion of “what is the case” is one that is very much alive.

Attempts to avoid the notion, exchanging it for the more, as it were, epistemically self-conscious notions of “what is verified” or “statement with maximum probability,” and so on, easily break down. These epistemically self-conscious concepts of knowing break down in a way similar to concepts of knowing that try to do without a separate truth requirement: we generate the possibility of both p and not- p being true, or of p remaining true at one date and at a later date not- p being found to be true, and remaining true.¹⁸

Critical Inspection of Arguments in Favor of Incorrigibility as Unattainable

At this point there is a further possible objection to face. In asserting that incorrigibility requirements arise in view of experience of past mistakes, we assume we are justified in stating that mistakes have occurred. But what justification for this is there? What justifies us in stating that the evidence

for a mistake was of a high standard? And in making these statements, what kind of announcement do we make? If we claim to know all these things on which our critique of incorrigibility rests, surely there is an inconsistency somewhere? But if that is the case, are there not serious repercussions on the argumentation in the previous sections?

Let us first see what happens if the view that incorrigibility cannot be reached is expressed in the terminology of “knowing.” Suppose the view goes as follows: “‘I know that p ’ is true only if it cannot be false that p , but I know that p may be false, that p is corrigible, that there is a source of error.” But the truth requirement can be applied to the latter statement too. Hence we get, “It cannot be false that I know that p may be false” and “It cannot be false that I know that p is corrigible, that there is a source of error.” Now it would hardly be reasonable of the proponent of this view to accept these second-order statements as incorrigible; to do so would be to falsify the view. Besides, there seems no reason to suppose that he alone should be immune to sources of error. At the stage of the dialogue at which the first-order statements were rejected, he will also reject those of the second order. That is, he will not consider their knowledge claim warranted—or better, he will abstain also in these cases from considering whether the known/not-known distinction is applicable.

What now are the repercussions on his argument concerning the first-order statements? Does the argument collapse leaving the field to the advocates of cases of incorrigibility?

It does not collapse. The knowledge claim could be retracted (as an inadvertence), and a new mode of announcement could be adopted, any other mode of cognitive *relevance*. The mode of announcement need not be explicitly expressed. One may inform people, in a preface, that in what follows, certain convictions, beliefs, or hypotheses are not put forward as assertions. Beliefs are good enough, and in forwarding a belief there is no implied incorrigibility claim. “I believe that p , but I may be wrong” is perfectly consistent. The same holds for “I am convinced that p , but p may be wrong.” It is, as was already pointed out, not necessary to prefix every contribution to the case against the attainability of incorrigible statements with an “I believe that . . .” or some other announcement different from “I know that.” It might be misconstrued. The point, of course, is not to inform people that I have this or that *belief*. Therefore a preface is better.

In short, the disbeliever in incorrigible statements is not handicapped in an argument because of his disbelief. He can have no wish to pretend, nor get any benefit cognitively by pretending, that his arguments are incorrigible, and he can without loss leave the “knowing” terminology and the conceptual framework alone.

There is another objection to be faced by those who dispute examples of incorrigible statements, namely that in citing sources of error, they are speciously removing themselves from the real situation and putting themselves, or the example, into an imaginary one. For instance, in countering Austin’s telephone example, we are simply inventing sources of error; as regards to the pig, it is simply known that Austin did not have amateur magicians as acquaintances. All we are entitled to say is something like: Very well, I concede that the world happens to be such that these statements are incorrigible. But there are many nonexistent yet conceivable worlds, some of them highly exciting. In one of them the “telephone” was not a telephone and the “pig” suddenly exploded like a balloon, leaving a new smell, that of helium. If it was a pig, it was certainly a very peculiar one.

The argument that sceptics must take the world as it is can be given the following form: Given human standards of credulity and the frequency and manner of our being deceived, it does not affect the issue of scepticism that other beings might have been more easily discouraged and so become sceptical. That they might be sceptical is of no more interest than say, for physical theory, the observation that if the earth had or developed a much greater mass than it in fact has, we should not be able to walk.

This kind of attack is serious, but not altogether convincing. When the disbeliever of incorrigible statements points to a source of rather astonishing mistakes, the erratic behavior of practical jokers or amateur magicians, it is his conviction that it is just *our* world that contains the source—and James Jeans and others *may* be right in their suspicion that there are few similar worlds in all the Milky Way. The more details that a believer in an example of an incorrigible statement hands out, the more concrete the disbeliever is able to make his indications of sources of error. They may be very far-fetched, and the believer will, I presume, always be able to modify his example so as to take care of a suggested source of error $n + 1$. But the sceptic is likely to conceive of a source $n + 2$. No conclusion of the debate is foreseeable, and the field remains divided between the contesting parties.

It can also be pointed out that any insistence that the world must be taken “as it is” itself implies a partial scepticism. The rejection of both Academic and total Pyrrhonian scepticism in British philosophy is a case in point. Its scepticism consists in its disbelief or doubt in styles of life, ways of experience, and views of the self and the universe, *Weltanschauungen*, that distinctly color even everyday life. Our daily life is supposed to be something we all have in common, and in it words get their distinct meanings. It is therefore supposed to furnish a common inescapable, nontranscendable frame of reference. This in spite of poets’, prophets’, and philosophers’ testimony to the contrary. Indeed, this testimony is taken not only to be highly suspicious but also misleading: whatever has been said to the contrary, all men live in exactly the same world, the world of common sense.¹⁹

In German philosophy, in Kantian and phenomenological trends, Pyrrhonian and Academic scepticism is also rejected, but the counterarguments are characteristically different from those of Austin and Ayer and others. Instead of an appeal to institutions of everyday life, there is an appeal to absolutely basic insights and principles that make doubt impossible *überhaupt* (in general). The principle of identity, of contradiction, the axioms of mathematics, and similar highly uneveryday themes are embarked on.

Edmund Husserl’s famous refutation of scepticism (in his terminology) is worth considering even if it is directed against negative dogmatism (Academic scepticism in Sextus’s terminology) rather than against the Pyrrhonist.²⁰ A theory as a piece of knowledge is, according to Husserl (1913), a kind of proposition that claims truth, is certain of its truth, and is justified in claiming truth. (One is reminded of the sets of three requirements for asserting “I know that *p*.”) Theories such as “There is no truth,” or “There is no knowledge” deny something they must accept in order to claim what they do. They are inconsistent, and the inconsistency can be proven.

From the point of view of the Pyrrhonist, both the negative dogmatism of “There is no knowledge” and the refutation by Husserl are open to the charge of rashness. Arguments about the necessary conditions for the possibility of a theory *überhaupt* are typical of philosophical arguments within formidable conceptual systematizations. The modern Pyrrhonist would, I think, point to the nonevident conditions for the possibility of constructing theories about necessary conditions. The development of theoretical phenomenology has exposed the intricate maze of questions surrounding

concepts of evidence functioning to establish what Husserl calls “the evident conditions of the possibility of a theory *überhaupt*.”

To those who believe in a universal everyday life or in certain basic insights, the testimony of Sextus Empiricus and others about mature sceptics with their complete suspension of judgment has to be rejected. The testimony must be *false*; the sceptic is suffering from self-deception.

Our Penultimate Conclusion on Modern Scepticism

We have examined arguments against the reasonableness of saying “I know nothing” and against the assertion that there are no incorrigible statements. It appears, however, that there are circumstances making it reasonable to use expressions like “I know nothing” and “No statement is incorrigible.” The realization that even in mathematics and logic, as well as in sense experience, statements are sometimes withdrawn and their negations asserted, sometimes even both assertion and negation withdrawn and the issue left undecided, gives the expressions a legitimate function in conveying an appreciation of the history of human error and of the reversal of truth claims. But such expressions do not function cognitively, that is, they do not serve to express conclusions for which a general validity is claimed. In fact, both for these expressions and the more radical ones of the Pyrrhonist, it is hard to find any satisfactory role in epistemology or in philosophical systems in general, if only because they are apt to be self-defeating when expressed in the precise way proper to their use in philosophical discussions.

Our conclusions are therefore extremely qualified compared with those that would have been expected to emerge if our discussion had been firmly anchored in a set of precise definitions. They can be expressed as follows: (1) “I know nothing” can be a reasonable assertion in certain circumstances, but it has to be understood in the context of the circumstances that make it reasonable. (2) There are no incorrigible statements, although it is only pertinent to attach significance to this in certain situations.

What needs to be stressed is the very special character of an endorsement of “I know nothing” or of the inapplicability of the distinction between known and not-known. The important point is this: The endorsement does not have consequences for the socially established standards of evidence, but reflects the socially accepted, indefinite fluctuability of standards. It re-

lates to special categories of dialogues in which there is created a conceptual framework of a special kind. In relation to such dialogues, and only in relation to them, the endorsement of the extremist formulation is tenable.

However, the so-called sceptical position in current discussion is mostly interpreted precisely as having consequences for the usual, that is, average standards. The so-called sceptic is a critic of those standards and denies the justifiability of *any* knowledge claim. Thus Arner (1959: 87), who has the sceptic conclude “that we never properly claim knowledge.” The distinction between verification and justification (stressed by Anfinn Stigen [1961, e.g., p. 266]) can be of some help here. I justify a claim for definite purposes, facing definite persons in definite situations. In doing so I may sometimes be rash, sometimes overcautious, the weight of evidence being the same in all cases. The mores covering the transactions take cognizance of series of failures, but they also take cognizance of successes.

It would be irresponsible to spread the rumor indiscriminately, that is, to any listener in any situation, that no statements are incorrigible, that strictly speaking we know nothing, or know no empirical statement to be true.²¹ Or, on the basis of considerations in the foregoing, that standards of evidence need a general uplifting, or, that one ought to stop talking in terms of knowing or knowledge because the hazards are too great. These are highly startling and “significant” pronouncements that are certainly misleading and without foundation in the foregoing conclusions.

There remain, however, results of interest to any serious student not only of the social psychology, sociology, and other branches of the nonformal (future?) sciences of knowledge, but also to anyone interested in contemplating human efforts to reach new knowledge and to improve the quality of the knowledge they have. Some such results and hypotheses may—at the risk of repeating what has already been said—be stated as follows:

1. There is within a community no definite stable *general* standard of evidence that must be fulfilled in order to justifiably say “I know that *p*,” where *p* is any statement that can be grammatically inserted.
2. There is not even a definite stable *particular* standard for any particular *p*, although there are approximations to stability. There are, therefore, no “usual” standards that most people most of the time find satisfactory in their normal working, in contrast to “special”

standards for special purposes. The fluctuations of standards are not exceptional happenings, but part of their normal working.

3. Two of the many factors influencing the level of standards for knowing are:
 - a. The stage and direction of the dialogue in which a particular statement occurs.
 - b. The responsibilities and risks incurred if it should happen (should later be agreed on) that p is false.

On the whole, as evidence is more closely inspected, as more failures of high relevance to p are reported in early stages of the dialogue, or as participants in the dialogue about p grow more divided in their opinions about p , the standards for knowing will also increase.

Further, the graver the risks and responsibilities, the higher the standards necessary to avoid being subjected to social retaliations in the case of failure. Sets of rules or theoretical models can be constructed more or less fitting the occasional explicit rules already verbalized in the community and the actual behavior of the individuals considered competent.

4. However the rules may be formed in detail, there should be one from which a prohibition of the expression “I know, but I may be wrong” can be derived. That is, it is clearly the part of the function of “I know that p ” to vouch for or guarantee that p is true and not false. Therefore clear indication of a source of error may exclude the use of “I know that p .”
5. If the competent user of language and well-adjusted individual perceives a source of error at the moment of using, or at the moment of forming words in which he might possibly include an “I know,” he will not withhold “I know” unless this source is of an important or probable kind—that is, only if it seems more or less likely that p will actually turn out to be false. Otherwise it is not worth mentioning. The situation for the users of “I know” is different from that of the neutral (or more or less neutral) bystander who (1) studies the community and (2) studies sources of error *independently* of the particular situation or interaction in which the utterer of “I know” happens to be placed.

The bystander will normally find many sources of error that do not occur to the user of “I know.” Some of these will be such that the

user, on being made aware of them, will ignore them, taking them to be of a completely negligible order of magnitude, or of a kind that all users are aware of but implicitly agree not to consider. ("There may be a war," "The sun may not rise tomorrow," "Our historical textbook may be completely wrong," and so on.) Some will be embarrassing to the user of "I know," not because the standards of the community are such that it should have occurred to him as a source of error, and should have made him abstain from using "I know," but because he will normally take any source occurring to him as ipso facto a sufficient reason to refrain from using "I know." The bystander disturbs the delicate adjustment.

6. Nearly all cases in which an "I know that p " is well placed are such that one might very well have *not* known that p . This means that platitudes are generally not introduced by "I know that," but that, on the contrary, very many statements that to the bystander involve clear sources of error *are* thus introduced. It is therefore out of the question for him to take the actual use of "I know" as conforming or even intending to conform to a rule of incorrigibility as understood and operated by a neutral bystander.
7. If he makes the sources and frequencies of error a subject of special study, the epistemologist *continues* dialogues (of a kind rarely observed in the community) with such a tenacity and stress on explicit conceptual frameworks that he must be considered a more or less neutral bystander rather than a member of the community in these matters.

At such stages of the dialogue on a given p , or on knowing in general, it is reasonable to hold that *no statement is incorrigible*, and that the known/not-known distinction decreases toward zero in applicability with increasing stress on defining knowing within a precise conceptual framework.

8. Among fellow epistemologists, the results of the studies may well be expressed by "I do not know anything" or "Knowledge cannot be reached," but only as part of a report containing many reservations and qualifications and stating some assumptions or postulates governing the study. Announced to the epistemologically innocent user of "I know," and particularly in situations in which he is just making use of that phrase, the epistemological formulations are grossly

misleading, inevitably being interpreted in ways that are not intended.

Thus, it seems to me that the study of “I know” is not a profitless or pointless study, and that interest in it is not reduced because the results are of no or little application to the so-called everyday life of the users of “I know.” After all, the everyday life is not the life we live *every* day, and the limitation to the ordinary is itself extraordinary.

My conclusion on modern scepticism can be put as follows: If by scepticism or “epistemological scepticism” is meant a doctrine expressible by “There can be nothing known,” “No statement can be known to be true,” or “No empirical statement can be true” without essential and severe qualifications and reservations, then scepticism is untenable. If, however, the reservations and qualifications suggested in the foregoing are made, then such scepticism is tenable. But its most adequate formulation, as I have tried to show, is in terms of the inapplicability of the known/not-known distinction in relation to any suitable explicit conceptual framework.

Our Ultimate Conclusion on Modern Scepticism

The arguments I have offered both in this and the previous chapters are designed to give support to the Pyrrhonian sceptic. The discussion as a whole is an attempt, on the part of a sympathetic metasceptic, to defend the Pyrrhonist against various undeserved objections. Some of these objections can clearly be met. In the case of others, it may be less obvious that a satisfactory answer has been provided. In some cases, perhaps even in most, it would be wrong to say the counterarguments against those who dispute the possibility, or plausibility, or sincerity, of scepticism were decisive. But, of course, the radical sceptic, too, would fail to find them decisive. Perhaps our own conclusions here should be genuinely sceptical. After all, the conclusion that there are no incorrigible statements might seem to be based on such doubtful case studies as to cast doubt on its tenability. It might be appropriate to wonder whether the requirements of evidence are so low that it might also not be possible to deny a thesis on the nonexistence of incorrigible statements.

Yet another counterargument might detract from the acceptability of our conclusions. If our study of candidates for incorrigibility is based on our

own experience of the correction of mistakes, we should note that every case of correction of a mistake is based on certain assumptions. If for p we insert " q is a mistake" in our formulas, we get statements such as "I know that q is a mistake," and the incorrigibility requirement that at one stage in the dialogue was found to be unsatisfiable is once more applicable. We should not say "I know that q is a mistake, but q may be true." If the incorrigibility requirement forces us to admit that no claim that a mistake has been known to occur can be accepted, it must be admitted that there is no *known* case of somebody having been mistaken in saying "I know that p ." More correctly, "I know that N. N. was mistaken when saying 'I know that p '" is always to be rejected as a claim to know; the incorrigibility claim involved cannot be satisfied. The same also holds for "I know I may be mistaken," "I know the incorrigibility requirement cannot be satisfied," and, of course, "I know knowledge can never be reached."

I must confess that there are arguments against my conclusions, and that my own arguments are not such as to compel acceptance, either in the reader or in their author, and certainly not in the mature sceptic. On the other hand, to be content with conclusions based on arguments so *obviously* incapable of winning the sceptic's acceptance would hardly be a convincing demonstration of the metasceptic's sympathy for his subject matter.

Series Editor's Introduction

Arne Naess — A Wandering Wonderer: Bringing the Search for Wisdom Back to Life

[The pre-Socratics'] attitude, in the main, was genuinely scientific whenever it did not merely embody the prejudices of their age. But it was not *only* scientific; it was imaginative and vigorous and filled with the delight of adventure. They were interested in everything—meteors and eclipses, fishes and whirlwinds, religion and morality; with a penetrating intellect they combined the zest of children.

From this point onwards, there are first certain seeds of decay, in spite of previously unmatched achievement, and then a gradual decadence. What is amiss, even in the best philosophy after Democritus, is an undue emphasis on man as compared with the universe.

Bertrand Russell, *History of Western Philosophy*

When the full scope of Arne Naess's philosophical contribution is examined carefully and placed in context, it will very likely be viewed as one of the twentieth century's most significant and enduring.¹ Naess has made bold and innovative contributions to conventional academic philosophy and social research, particularly in the areas of behaviorist epistemology, empirical semantics and communication theory, scepticism, scientific and cultural pluralism, Gandhi and Spinoza scholarship, normative systems theory (as a general approach for exploring premise-conclusion relations), and the very idea and relevance of total systems (total views in Naess's *lingua*). Perhaps even more significant—although one should not view it as distinct or decoupled—has been his commitment to reconnect philosophy to life experience. This effort is similar to Bertrand Russell's in that it has been particularly pronounced in later life. Naess, however, carries this com-

SERIES EDITOR'S INTRODUCTION

mitment to expand philosophy's sphere of concern to life in general and the Earth. Essential to this endeavor, is the mature Naess's radical initiative to reconceptualize reason expansively, to integrate reason with emotions and feelings *in practice*. In some cases this includes using mythopoetics to make a case or communicate a point.² What makes Naess so special is that even while paddling against the current, he exhibits tremendous optimism and openness, joy, and a disarming, infectious playfulness.

Naess strives to *live his philosophy*. For more than thirty years, he has sought to reshape the philosophical debate by drawing from and building on his previous work to outline a nondualistic, nonanthropocentric philosophy of life that affirms the ultimate unity and interdependence of all living beings, while maintaining their individuality. His philosophy celebrates the Earth's richness and diversity—both cultural and biological. That said, one of the main purposes of the *Selected Works of Arne Naess* (SWAN), however, is to provide you, the reader, with the resources to make your own informed judgment regarding the significance of Naess's philosophical legacy.

At age ninety-two, Arne Naess has lived a long life filled with wonder. In his words, he has “seen life”—traveling the world, spending significant periods of time on every continent. He has experienced the world somatically and intellectually in concert as one mind-body—as a being—and seen more than most of us can imagine.

When Naess was born, Archduke Francis Ferdinand was alive, automobiles were in their infancy, and most homes did not have running water. Home refrigerators had just begun to be produced. Television and computers were only imagined. Only a few years before, after being contemplated for millennia, the first controlled and sustained powered flight took place, ushering in a period of ever-accelerating transfer of materials and information, but not necessarily a commensurate increase in knowledge or wisdom.

Consider that Naess has lived through two world wars (and too many “limited” conflicts to count), the rise and fall of the Soviet Union and East Germany, the “liberation” of India and Pakistan, the onset of climate change, and the hastening of “global terrorism.” He has been the beneficiary of tremendous medical advances and unprecedented economic growth, and he has seen the ravages caused by escalating consumption, globalization, and disparities in both income distribution and access to resources. He is part and product of humanity's largest growth spurt. And he has witnessed the most significant loss of cultural diversity and the onset of

what may become the planet's greatest extinction crisis—but is surely the greatest extinction crisis ever caused by one of Earth's own species. Naess has also seen and, at times, participated in the many hopeful responses to these ills—the peace, social justice, and ecology movements; nonviolent actions to support antiglobalization efforts and protest dam building; voluntary simplicity; conservation biology; wildlands philanthropy; bio-regionalism; green business and architecture; ecological design, economics, engineering, and restoration; and sustainable agriculture, forestry, and fisheries management.

Everyone is influenced by the times and events of his or her day. The “prejudices of our age” filter into our lives and work more or less consciously and actively, but at a minimum they enter passively. What is the mature Naess's approach to philosophy, how is it a uniquely self-aware and responsive product of his day, and why should it be seen as monumental?

Naess likes to see himself as a “philosopher of life.” The thought of simply being an academic philosopher—living a life of the mind—makes him restless and uneasy. For Naess, “wonder” is both the point of departure for philosophy and the focus of the enterprise. He is the philosophical equivalent of a hunter-gatherer using his wits and intuition to seek out food (for thought) in a fecund landscape. As they were for the ancient Greeks, science and philosophy are inextricably intertwined for Naess. Science, as the application of reason through empirical investigation, cannot be separated from rational reflection on the nature of reason, and vice versa. For the mature Naess, though, philosophy and science are also distinct. Philosophy is the unique realm in which we take up the deepest, most profound, and most fundamental problems. From Naess's vantage, which defines philosophy openly and discursively, the questions that have fascinated and plagued people for millennia have not changed much and they are not likely to change significantly in the future.

Naess's view of philosophy includes the traditional epistemological question “What can we know?” and the ontological question “What main kinds of things are there?” But it also includes “How do we measure?” and “How do we know?” as well as “What is the relationship between the knower and the known?”³ These are questions that are likely to vary with cultural and social circumstances, but this does not, for Naess, imply cultural relativism. By its nature, this view of philosophy runs counter to the dream of the logical empiricists; it cannot be restricted to investigations of

SERIES EDITOR'S INTRODUCTION

“fact” or “logic.” It is imbued with fundamental valuations. Being a philosopher, for Naess, is thus a deeply personal and intimate matter that requires us to engage all of our powers and experience. It should also include questions such as “What are your aims in life?” and “What’s driving you?” as well as encourage a practice of deep and open argumentation by asking repeatedly, “Why do you hold that *p*?” in order to unearth underlying premises and hypotheses. For Naess, all these questions have an empirical component. He sees it as a duty for a philosopher to extend research into the creation and use of empirical methods to address these aspects, unless these questions can be adequately addressed by an existing empirical science, in which case it is fine for a philosopher to perform research here, but it no longer constitutes a *duty*.

In Naess’s view, philosophy is ultimately concerned with how *we*, through our experiences, perceive the world, the world’s relation to ourselves, and the basic features of the condition of people. It is the realm in which we pose sophisticated questions to address perennial problems, probe them from different angles (in Naess’s case, from as many angles as possible), and test and apply the insights to real life—to what we do and decide every day. Its purpose is not to arrive at definitive answers. The purpose of philosophy, rather, is to help us understand what *we* believe in from our innermost perspective, expand this perspective continually, and facilitate communication—so that we might contribute toward improving the state of affairs of the world.

While initially attracted to Bergson’s *les données immédiates de la conscience* (the immediate data of consciousness), Naess grew disenchanted when he recognized that one becomes lodged in an endless circular loop and never exits consciousness. Naess clearly believes that the unexamined life is not worth living (his life is a testament to Socrates’ edict), but he appreciates that disembodied, introspective examination comes at great peril. A mind-centered focus on “examination”—where subjects exist separately from objects, theory is isolated from praxis, and knowledge is decoupled from wisdom—very quickly degenerates into meaninglessness. Worse yet, separating people from and raising people above nature and the coevolutionary process that created us—and provides for our sustenance—can be inimical to life and the evolutionary process.

Nature, that which is, the reality of the pre-Socratics, is Naess’s philosophical palette, not the “world” of his own consciousness as has become

the norm with so many contemporary philosophers since Descartes. Popper and others posit the existence of three worlds that correspond to the development of our commonsense view of reality. World I is the physical world, the "external world," the world of our sensory impressions. World II is the world of all conscious experience, the psychological world of the "immediately given," which incorporates our feelings and intentions. World III emphasizes the logical content of reality. Naess finds these multiple views of reality unconvincing and potentially dangerous. With a worldview inspired by Spinoza's *Ethics*, he is fundamentally opposed to the notion of multiple worlds.

Naess's mature philosophical approach and contributions are shaped by full engagement with a relational reality, in which no firm subject/object, substance/property, universal/particular, fact/value dualities exist. John Muir's famous, deceptively simple aphorism sets the stage: "When we try to pick out anything by itself, we find it hitched to everything else in the universe." Reality as we experience it, according to Naess, is a dynamic, multilayered manifold of hierarchically related gestalts—of which we are always a part. It is the opposite of atomism. Contrary to the dominant, Western way of viewing reality, there are no extrinsically connected discrete objects or "things in themselves" in the sense of Kant's *Ding an sich*. With Naess's "gestalt ontology," there is no dualistic "I" standing outside of reality looking in. Living beings, individuals in the sense of Spinoza's modes, are spatiotemporal manifestations of "one substance," nature or reality. As Naess points out in *Freedom, Emotion, and Self-Subsistence* (SWAN VI), Spinoza's medieval terminology of substance, mode, attribute, God, and Nature is dispensable. In addition, Naess goes on to characterize "living beings" broadly to include individual organisms as well as ecosystems, rivers, mountains, and possibly Earth (Gaia).

Naess's view of reality calls for a gestalt shift. His gestalt ontology does not stop with gestalt psychology's simple notion of holism, where the whole is more than the sum of the parts. It goes on to add that the internally related subordinate gestalts are themselves more than mere parts. There are no parts as parts or wholes as wholes; higher-order wholes are not reducible to lower-order wholes. The concrete contents of reality have gestalt character. For Naess, we experience reality spontaneously and our experience of the world is made up of gestalts. "[This] is the world we experience. Nothing is more real."⁴ People create abstract structures to reflect

SERIES EDITOR'S INTRODUCTION

on or analyze spontaneous experiences and their structure; they are the interrelations between spontaneous experiences. Mind and body are mental contrivances and conveniences—abstract structures in Naess's parlance—for helping us to describe, model, or understand certain states of affairs. They are not the contents of reality. Only individual occurrences of spontaneous experience make up the concrete contents of reality.

What are the consequences of Naess's "ontological realism" as expressed in the form of gestalt ontology? First, living organisms have different levels of access to reality, based on their capacities, experiences, and backgrounds. This implication of "reality is one" plays a central role in the mature Naess's approach to philosophy of science. One of his main thrusts is to undermine the claim that the exact physical sciences show all that is, that they have a privileged view of reality. In his view, science creates extremely abstract structures of what is real, but those structures do not actually *describe* any of reality's concrete contents (descriptions are themselves normative). Jakob von Uexküll, the famous ethologist of the early twentieth century, whom Naess read closely in his youth, helps clarify this notion. "As the spider spins its threads, every subject spins his relations to certain characteristics of the things around him, and weaves them into a firm web which carries his existence."⁵

Different people experience reality differently, yet we often, incorrectly, speak of *different realities* as if they existed. By the same token, identical accounts of reality in no way imply verification of that view by correspondence; from Naess's perspective, such accounts by themselves are merely a sign of cultural poverty. "God" could have created the Earth and life 6,000 years ago, but the evidence to support this case is thin and the evidence to support evolution is stronger, in part because biological science and paleontology generally employ a greater level of depth of intention and thus aspire to maintain higher standards for the evaluation of evidence. Radical pluralism and scientific possibilism do not imply scientific or ethical relativism.

There are at least four other key implications of Naess's gestalt ontology. First, the existence of one, interdependent reality tends to curb solipsism. Second, the world we live in spontaneously can no longer be characterized as merely subjective. Expressions such as "the social construction of nature" become oxymoronic. Third, individual organisms exist as knots in a biospherical web or net. Reality is not anthropocentric; it is not particular

to humans. Fourth, humanity can no longer justifiably be seen in opposition to a separate object—nature. This insight tends to temper any “natural” tendencies toward anthropocentrism. As with Leopold’s Land Ethic, people become plain members and citizens of the biotic community, albeit ones with unique powers and proclivities and thus special responsibilities. We are all individual beings, yet we vary in the extent to which we are integrated into the whole.

Humans are massively altering the gestalt character of reality, diminishing it, making it less complex. We do this, Naess argues, without necessarily recognizing we are doing it or the extent to which we are doing it. Thus, we are unable to evaluate the tradeoffs of making such decisions. Naess argues that we generally act simply according to how we “see” reality, but there are aspects of reality that may not be available to us. These aspects are no less there because they are currently unavailable to us, yet they can be destroyed very easily. Sometimes we also confuse our abstract structures of reality (models, data, concepts, etc.) with the contents of reality and vastly underestimate the complexity of internal relations between gestalts, leading ourselves to believe, incorrectly, that higher-order wholes can be reduced to lower-order wholes. It is Naess’s hope that by embracing gestalt ontology, we are encouraged to cultivate our opportunities and faculties for experiencing reality more fully—for experiencing more complex, higher-order gestalts. It is also his hope that we will openly and more carefully consider, in advance, how a proposed research program, action, or decision might affect other peoples’ (or other life-forms’) opportunities for rich spontaneous experiences (consider, for example, the possible impacts of ostensibly beneficial research on nuclear fission or molecular biology). In the end, however, we should remember Naess’s own caution—his description of gestalt ontology is itself an abstract structure. As Naess says, “For me reality has always been something slippery to handle. I seem to grasp it firmly, but like an eel, or even a small lively trout in shallow water, firmness of grasp does not guarantee against escape.”⁶ But does reality really have gestalt character?

Truth—as in *the* truth—is not a defensible notion for Naess. For too many academic philosophers, wonder has been extinguished and replaced by a belief that definitive answers have been found, that the original, initially vexing questions can be laid to rest. Naess is under no such illusion. He views humans as essentially fallible and he sees this domain of fallibility

SERIES EDITOR'S INTRODUCTION

as extending to mathematics and formal logic. This may be why he so freely returns to previously explored material (sometimes just after writing it) and looks at it afresh, with new and frequently competing and even conflicting insights. For Naess, truth is something we seek continually without expecting or believing that it can be found. He seeks peace of mind (*ataraxia*) by suspending judgment (*epoché*). While necessity requires him to take firm positions in life, he often resists taking such positions in his written philosophy. Having reached a general state of mental suspense (*isothernia*), he prefers, as a mature sceptic, anticipating his own tendency to come up with counterarguments and counter-counterarguments, to suggest alternative paths, inspire new ways of looking at things, and foster informed, open-minded debate. This *zetetic* inclination, although nascent in many of his earlier works, was made explicit and became a central theme in his philosophical writings in the 1960s.

For Naess, passivity has no place in philosophy or life. In his famous debate with Sir Alfred Ayer, Naess defines Spinoza's *amor intellectualis* as a "kind of loving attitude towards what you have insight into, while considering it in an extremely wide perspective."⁷ For the mature Naess, *amor intellectualis* involves using his technical and intellectual training to articulate, in direct and forceful ways, his attitudes and evaluations on matters of practical consequence. Like Spinoza and Gandhi, Naess is concerned with human salvation in this world, but Naess, with his concept of "wide-identification," expands this concern to both humankind's relationship to life in general and the self-realization of all life-forms for their own sake. Whether it be understanding how lay people conceptualize truth or experts characterize democracy; considering how our approach to science not only shapes how we do science, but the nature of scientific outcomes too; using philosophy to improve practical communication; facilitating thoughtful debate on the potential dangers of Norway joining the European Union; or discussing the ethics of climbing, the meanings of sustainable development, or distinctions between different approaches for addressing the ecological crisis, Naess seamlessly connects philosophical questioning to activeness in relation to the questions.

Naess's philosophical career can be seen, in one sense, as an attempt to bridge C. P. Snow's two cultures. Believing that the central questions of philosophy are here to stay, he has developed his philosophy over seventy years in part through his effort to relate these questions to the issues of his

rapidly changing, trying, and tumultuous era. Naess's lifelong commitment to integrate interests in nature, science, and logic is evidenced by the mature Naess's championing of philosophical approaches in which both metaphysics and science contribute to all-embracing systems of thought. This approach is particularly prominent in Naess's development of normative systems theory, a strategy for promoting systematic reflection on premises and conclusions. Recognizing that all philosophical questioning must stop somewhere, Naess calls the essential intuitions that serve as bedrock assumptions for our total views, ultimate norms or ultimate premises. Further, recognizing that our philosophical conclusions as well as our lifestyles and everyday actions often appear inconsistent with these ultimate premises, Naess has developed a strategy for using premise-conclusion strings to help identify potential norm conflicts as well as to help assess whether potential agreements and disagreements are real or pseudo. Use of this technique figures prominently in Naess's approach for improving communication, in his approach for exploring both the philosophical basis for Gandhi's *satyāgraha* (active nonviolent resistance) and the Gandhian premise "Any human conflict can be justifiably resolved through nonviolence," as well as in his own Ecosophy T.⁸

With regard to total views—broad philosophical systems like Spinoza's, which attempt to communicate our deepest insights and communicate views of life—Naess argues that although the existence of complete, explicit total views is absurd, it is equally absurd to presume to criticize a total view without adopting one (at least implicitly). After relinquishing the possibility of creating a consistent empirical theory of knowledge, Naess came to believe that any theory of knowledge presupposes all major philosophical disciplines, at least on the metalevel. One cannot have a theory of knowledge without presuming a particular reality, at least implicitly, and this necessitates having an ontology, metaphysics, ethics, and so on. This has practical consequences too. We never simply act solely as a philosophy professor who specializes in logic or ethics; we are always, at least partly, mother, daughter, lover, scientist, . . . , and philosopher. If we accept the premise "For every decision we, explicitly or implicitly, take all things into consideration," then the notion of total views or total normative systems can be seen as very "useful fictions," which, if articulated, might help us to improve decision making.

Naess is careful to point out that he sees his own total view and others

SERIES EDITOR'S INTRODUCTION

as fragmentary and constantly evolving—ever “on the way.” Moreover, even if we could have a completely formed and integrated total view, we could not count on being able to articulate it. There will always be a tension between the Spinozistic goal of clarity and the pragmatic reality that in this world we can never wait until all the facts are in. None of these issues, however, justifies abdicating our responsibility to try to articulate our own total views. The mature Naess is a radical pluralist. He believes in defending coherent systems, without claiming that their relation to reality is definitive. While he is committed to the importance of models and systems, he is opposed to the idea that there could or should be a definite worldview. Naess's hope is that there will be no definite scientific worldview in the future.

No Western philosopher since Descartes—except perhaps Spinoza, who has also been a primary inspiration for Naess—has had the potential to help us drastically reshape our relationship to each other and life in general: not by spelling out *a* clear and coherent total system—to be taken as *the* truth—but by challenging us to articulate our fragmentary total views and connect the abstract problems of philosophy to issues of contemporary social and political conflict. In Naess's view, “[t]he full meaning of a theory can only reveal itself in practice, and practice is blind without theory.”⁹ To be a philosopher of life, one must embrace both theory and practice and engage them in dance.

In Norway, Arne Naess is regarded as a national treasure, a seeker and a seer, a “minor prophet,” in his own words. His radical pluralism and endorsement of diversity are demonstrated by his complex character. He has a proclivity for being aloof and charming, somber and joyful, accountable and carefree, arrogant and modest, slippery and precise. In a world of contradictions—breathtaking beauty *and* ineffable squalor and suffering—Naess is no exception. He is an antiguru guru. He strives for high levels of consistency and integration in his philosophy but accepts that in his personal life he cannot live up to his philosophical systems' requirements. He strives for definiteness of intention, yet he appreciates vagueness and eschews dogma, refusing to be pinned down to a particular viewpoint or placed in a particular philosophical camp. This stance is further supported by his sometimes maddening tendency to revise, revise, and re-revise. As a consequence, one cannot go to any of his books or articles and find the “definitive” Arne Naess. He is a

troublemaker too, but the kind of troublemaker people want to have around because he challenges orthodoxies with an elfin irreverence. Naess stands out because his frequently outlandish and controversial views are felt deeply, reasoned carefully, and conveyed playfully.

Naess has had a profound influence on Norwegian academic life and the society as a whole. From 1939 to 1954 he was Norway's only professor of philosophy. He was chiefly responsible for organizing courses for the *examen philosophicum*, introductory examinations in logic, methodology, and history of philosophy that an entire generation of undergraduates (roughly 100,000 people) were required to take, regardless of their disciplinary focus. His unique paradigm of inquiry—emphasizing open-mindedness, empirical analysis, pluralism, a thorough grounding in philosophy and the history of ideas, and a vital concern for contemporary problems—is credited with shaping the intellectual fabric of postwar Norway. At a press conference for Naess's eightieth birthday, the Norwegian Minister of Education testified to the significance of the Norwegian version of Naess's *Communication and Argument*, one of the primary texts for the *examen philosophicum*. "We have all read it. We *still* cheat in argumentation, but now with feelings of guilt."¹⁰

Naess is also credited with rekindling the study of philosophy in Norway and with forming the Oslo school of philosophy. The section on Scandinavian philosophy in *The Encyclopedia of Philosophy* elaborates:¹¹

The philosophical milieu in Norway today [circa 1967] is determined by an internationally known and original philosopher. . . . Arne Naess . . . is the originator of a radical type of empirical semantics and the leader of the so-called Oslo group. . . . The empirical methods applied by the Oslo group employ carefully worked-out questionnaires. By the help of such questionnaires and by teamwork, philosophers of the Oslo group have carried out investigations of such expressions as "truth," "democracy," and "private enterprise." . . . If it is correct that Norwegian philosophy has had a dead period,¹² it is equally correct to assert that, primarily because of Arne Naess, Norwegian philosophy is now in the middle of a period of life and growth.

When asked to comment on this passage, Naess was emphatic about inserting an addendum to the last sentence.¹³ He was proud to convey that contemporary Norwegian philosophers pursue a wide variety of directions and employ a diversity of approaches, many independent of Naess's own line. This point is borne out by the more than forty-four permanent teaching positions currently at the University of Oslo's Institute of Philosophy

SERIES EDITOR'S INTRODUCTION

and the broad spectrum of approaches these philosophers pursue, from the analytic tradition to phenomenology and from existentialism to hermeneutics. As one of Naess's successors, Alastair Hannay, in his section on Norwegian philosophy in the *Oxford Companion to Philosophy*, has commented, "Norway enjoys a varied and vigorous philosophical life. . . . Philosophy's place in Norwegian academic life, as in the society at large, is due in large measure to Naess."¹⁴

The reach of Naess's contributions to philosophy and social research extends well beyond Norway. Significant international recognition has also come his way for these contributions. He has received the Peer Gynt Prize awarded by the Norwegian Parliament (2004), the Nature and Environment Prize from the Nordic Council (2002), the Nordic Prize from the Swedish Academy (1996), the Mahatma Gandhi Prize for Non-violent Peace (1994), and the Sonning Prize for contributions to European culture—Denmark's version of the Nobel Prize (1977). He has even been honored by five festschrifts, one each for the occasions of his seventieth, eightieth, and eighty-second birthdays and two for his eighty-fifth birthday.¹⁵ He is the founding editor of the influential journal, *Inquiry*, created to promote collaboration between philosophers and social scientists. He is also a renowned mountaineer and climber, an occasional nonviolent political activist, and father of the deep ecology movement. His social concern, sense of wonder, and trickster nature have all contributed to his success at numerous academic posts around the world—preferably near mountains or deserts—from Berkeley to Jerusalem and Helsinki to Hangzhou. He is, to this day, still a frequent international speaker.

Even with this high level of accomplishment, the significance of his work as a whole—as a gestalt—has yet to receive broad-scale appreciation outside of Scandinavia. There are many explanations for this situation.

The overarching reason has likely been the general inaccessibility of his oeuvre. This inaccessibility has many facets. Naess has been incredibly prolific, producing over four hundred publications, more than thirty of which are books. These publications span topics from argumentation theory to zeteticism, with adventures along the way at such seemingly incongruous destinations as climbing ethics, cultural anthropology, and deep ecology. His range of topics—in abundance, breadth, and depth—is trying, at best, for our increasingly compartmentalized and specialized academic communities.

In addition, the bulk of his most significant works have been out of

print for quite some time. Many of the earlier editions of the books were edited poorly and documented sparsely. A significant portion of his important articles and book chapters appears in obscure or difficult-to-find books and journals, and much of his work has remained unpublished (at least two hundred papers and several book-length manuscripts). Naess's main works appear in three primary languages, German, Norwegian, and English, although he has also written in Danish, Swedish, and French. Finally, Naess's prose can be dense and opaque, if not downright confusing. Although this trait is by no means unusual for a philosopher, when blended with Naess's appreciation for vagueness and ambiguity, his aversion to authoritative stances, and his tendency to revisit topics by reconsidering earlier viewpoints, the already high entrance fee can become prohibitive.

The boundless range of Naess's interests and the general inaccessibility of his entire oeuvre have led some scholars to view him rather pejoratively as a dilettante. Some of these critics view him as flitting from one area of interest to another, not mining any to its logical conclusion; some see him as throwing away a great talent in logic; some view his social research, especially his work with questionnaires on lay people's and experts' perceptions of philosophical concepts and his use of statistics, as outside the realm of serious, professional philosophy; and still others see him as inappropriately conjoining his philosophy with activism. His breadth has even led a few of the more extreme critics to dismiss his work out of hand. Although some of the criticisms detailed above do have merit, in my view Naess gives the dilettante a good name.

To address this range of concerns, the *Selected Works* project was conceived. The project was the brainchild of Douglas Tompkins. "Miracle Doug," as Arne refers to him, is the founder of the Foundation for Deep Ecology and is himself a renowned climber and kayaker in addition to being a wildlands philanthropist who has helped protect immense tracts of land in Chile and Argentina, some as large as Yosemite. The *Selected Works* would have simply remained a "great idea" without Doug's generosity and support. The project was initiated in 1994 and commenced editorial work in 1996 under my direction.

In the introduction to his *Four Modern Philosophers: Carnap, Wittgenstein, Heidegger, and Sartre* (1968), Naess decries the condition whereby the philosophical life of an individual is set by the local philosophical scene, by provincial biases, or by what is easily accessible.¹⁶ Such accidents of envi-

SERIES EDITOR'S INTRODUCTION

ronment should not, in Naess's view, play a pivotal role in shaping a budding philosopher's development. I see the *Selected Works*, at least in part, as a response to this predicament.

The purpose of the *Selected Works* is to bring—for the first time—the full scope of Naess's philosophical contributions to the English-language audience in one collection of highly readable and meticulously edited volumes that adhere to the highest standards of contemporary academic philosophical publishing. The *Selected Works* is, however, by no means exhaustive; it is not a collected works.¹⁷ We have simply aspired through careful selection to offer a representative and relatively expansive collection of Naess's principal writings. As such, the *Selected Works* is the definitive repository of Naess's oeuvre, chronicling the development and progression of his thinking for scholars, students, and critics alike.

In the remainder of this essay, I attempt to sketch briefly one possible version of an intellectual biography for Arne Naess. I endeavor to trace some key influences on Naess's philosophical development, discuss the evolution of his philosophical outlook, and touch on the relevance and significance of each volume in the *Selected Works*. I close with a short note on our editorial approach.

From Scientism to Wisdom: Toward a Philosophy of Life

The philosophic researcher should be task-minded, not discipline-minded,
and should follow his questions wherever they lead.

Arne Naess, "Norway"

Arne Dekke Eide Naess was born in 1912 in the dining room of a large house with a wild, expansive garden. The house was on the outskirts of Oslo in Slemdal, a short walk from where Naess lives today. Arne was the unplanned fourth child of a wealthy family from Bergen. Before he was a year old, his father, who was ill with cancer, had died. Overwhelmed, his mother, Christine, entrusted little Arne to the family's governess. This is where his first memories begin.

Arne speaks of Mina, his governess, endearingly. She is described as satisfying little Arne's every wish, be it procuring live flies for his bath or bringing a trunk filled with bottles on a family trip so that he could continue his water-play experiments. Sometime before Arne was four, Christine dismissed Mina, ostensibly for spoiling Arne too much. This initiated a deep

rift between Arne and his mother, which was never to be mended. It also set in place a sense of loss, alienation, and resistance to emotion that profoundly influenced Naess's early personal and philosophical development.

Significantly later, after an intensive six-day-a-week, fourteen-month psychoanalysis with Freud's noted collaborator Dr. Edvard Hitschmann, Naess came to understand his impenetrable shell that keeps others at arm's length (*Panzercharakter*, in Freudian terms) as resulting from a reaction to his mother's unreliability and emotional hysteria. His effort to keep his mother at a distance morphed into a general aloofness and distancing. The adolescent Arne began to favor an "objective," bureaucratic approach to language. He saw art, music, and poetry as being seduced by emotion, by beauty and form, but viewed science and philosophy as realms from which such emotions should be banished. This prejudice would take decades to overthrow. At this time he also developed a single-mindedness and resistance to inconvenience and pain that to this day make it easier for him to concentrate and focus. As Hitschmann pointed out, however, this inward turn has a flip side, a certain self-destructive or masochistic bent that was later to plague him, particularly in his relationships with women and his children.

Much of Arne's early childhood was spent at the seashore, and this is the period in which his interest in nature and experimentation began to flourish. Feeling somewhat distanced in his relations with people, he identified with nature, especially little sea creatures. He waded in shallow water for hours, inventing experiments to test nascent hypotheses about the behavior of small sole, tiny translucent shrimp, and crabs. He describes these experiments as engendering an early enthusiasm for diversity and a tendency to suspend judgment on the nobility or status of different beings. He loved these creatures for their unique qualities and their amusing adaptations and limitations. They inspired a certain egalitarianism, which took hold and later influenced his philosophical approach in profound ways.

Young Arne was restless. He had an early penchant for "collecting" and organizing large groups of numbers, stones, and stamps. He started climbing trees in the family's little "wilderness" before he was five and soon progressed to big firs and spruces. He found that he enjoyed being able to watch people from above. Arne outgrew trees fast. His desire for perspective and the opportunity to survey broad areas was rapidly transferred to mountains. At the age of five, he began going to his mother's small moun-

SERIES EDITOR'S INTRODUCTION

tain cottage in the town of Ustaoset, high in the Hardangervidda between Oslo and Bergen. By the age of eight, he had adopted Hallingskarvet, a bread-loaf-shaped mountain about three and a half hours' walk from Ustaoset, as his surrogate father. In his teenage years, this obsession for expansive perspectives translated into a lifelong passion for mountaineering. When Naess was sixteen or seventeen he climbed the 106 tallest mountains in Norway. It was around this time that he was first introduced to Spinoza's *Ethics* by a Norwegian Supreme Court justice that he met in the mountains. Naess's desire for a broad and open perspective, for seeing things in totalities (god's-eye view), translated to his studies. Young Naess read widely in economics (especially value theory), science, philosophy, history of philosophy, and the Earth's biological history.¹⁸ This commitment to cultivate an ever-expanding perspective would later potently influence his approach to philosophy.

Arne's youth was spent captivated by piano, study, and mountains. His decade-older brothers took it upon themselves to toughen up their timid younger brother, as well as introduce him to the ways of the world and scholarship. When Arne was only eight, his eldest brother, Ragnar, left for America to study for a Ph.D. in chemistry at MIT. Ragnar later went on to receive one of the Harvard Business School's first degrees and became a successful stockbroker in the United States. Erling studied economics and went on to create an international shipping empire; he became famous for his assistance to the Norwegian government-in-exile during the Nazi occupation. His sister, Kiki, married a German doctor and after the Second World War returned to Norway to become a physical therapist. From Kiki he learned the power and significance of offering encouragement to others. During his early years and well into adulthood, Arne's tight-knit relationship with his siblings provided security and support for him to "find his own way" — *sva mārṅa*, to use one of his favorite Sanskrit terms. Although he tended not to seek their financial assistance, his wealthy and generous brothers offered a sense of comfort, safety, and the occasional extravagance, which in later life made it easier for him to live his bon mot, "simple means, rich ends."

Naess studied philosophy, mathematics, and astronomy at the University of Oslo. At nineteen, after completing the equivalent of an undergraduate degree, he left Oslo to continue his studies in Paris. Naess was put off by the adoration Bergson received in Paris, but ultimately left to seek

broader vantage points, cheaper living, and better climbing opportunities. After completing two master's theses at twenty-one, one exploring discussion about the concept of truth and the other exploring the use of behavioral psychological principles to judge truth validity, Naess left Oslo again, this time for Vienna. In Vienna he took master classes in piano, where, following his trickster nature and as a response to the strict taskmaster Fuchs, he "learned" new material. When he ran out of pieces he had long since mastered, he quit. Thinking that it was necessary for philosophers to have high levels of self-knowledge, he underwent intensive psychoanalysis with Dr. Edvard Hitschmann. As a part of that process he assisted with the treatment of patients in a psychiatric hospital and developed tremendous empathy for the suffering of humankind. While in Vienna, he was also warmly welcomed at the famous Schlick seminar.

The logical empiricists' friendly, equiminded approach to discussion made a great impression on Naess, but he was not equally affected by their ideas.¹⁹ The young Arne was impressed by the preciseness, empirical nature, and lack of emotion in science—he wanted to practice philosophy with a scientific bent and he wanted to test philosophical hypotheses with experiments. He was already interested in perennial philosophical problems and did not believe that most of them were ultimately pseudoproblems that could be solved by investigating inconsistencies in language. His most significant philosophical issue with the logical empiricists was not that they were empirical, although he believed they were misguided in thinking that any philosophical problem could be wholly empirical, but that they were ultimately antiempirical in their belief that a logical grammar of language was more suitable for investigating the use of terms than statistical analysis of their actual use. Naess's detailed critique of the logical empiricists' position and reflections on his personal experiences attending the Schlick seminar appear in volume VIII. In this critique, Naess expresses a concern that in their interpretation of terms, many philosophers (not just the logical empiricists) were artificially constricting the range of possible interpretations and thus unintentionally reducing potential insights regarding the diversity of tenable positions on problems of vital concern. This perspective presaged his later views, particularly those expressed in *Interpretation and Preciseness* (SWAN I), and his later approach to cultural anthropology and philosophy of science. Naess sums up his general perspective on the state of philosophy at the time with the following remark: "The

turn of (Western) philosophy in [the twentieth century] towards language rather than cosmos, towards logic rather than experience in the broadest sense (like that of William James), is a turn into a vast blind-alley."²⁰

While in Vienna for fourteen months in 1934 and 1935, Naess made final revisions to his doctoral thesis, *Erkenntnis und Wissenschaftliches Verhalten* (Knowledge and scientific behavior).²¹ Although Naess drew inspiration early on from Russell and Whitehead, his doctoral thesis can be seen, in part, as support of the American Pragmatists (James and Dewey) in opposition to Russell and early Wittgenstein. According to Dewey, the main purpose of his philosophical writings was "to reintegrate human knowledge and activity in the general framework of reality and natural processes."²² Naess did just this by creating a radical and unique approach for exploring how high science is performed, a sort of science of science. At this point, Naess believed it was possible to use such an approach to obtain a complete account of all science within one system. Inspired by the ethologist Uexküll's "special biology" (*Umweltforschung*), Tolman's "objective" behavioral psychology ("molar" behaviorism), and the cultural anthropologist Malinowski's work on speech and nonverbal behavior, Naess took on the standpoint of a neutral, nonparticipant spectator and outlined a program for an empirical metascience of science, an ethological approach to epistemology of science.

Naess used the idea of a dispassionate visitor from another solar system coming to study Earth-based scientists to demonstrate the possibility of completely describing both the activity of researchers and the contents of knowledge without drawing on the subjective models that governed traditional epistemology and presupposed knowing subjects or minds. The idea was to study or rather "witness" science similar to the way experimental psychologists study rats, but without falling into the trap of imposing their own experience of reality and their preexisting conceptual models of reality ("maze epistemology"), or their scientific pretensions. In the view described in *Erkenntnis*, knowledge is cognition—it is an activity with intention—and this helps to dismantle the subjectivist dualism between the content of knowledge and the activity of research. Naess's interest was in describing these patterns of research activity. He argued that the *terminology* associated with scientific activity—which is bound to the subjective-reality model—changes in leaps and bounds, not the *patterns of research activity*, which are in constant, but gradual, flux. With this argument that

change in science happens gradually, by generalization and differentiation, Naess foreshadowed his response to Kuhn well before *The Structure of Scientific Revolutions* was published in 1962.

With *Erkenntnis*, Naess also anticipated ideas that later became prominent in linguistic philosophy, such as the importance of ordinary language over formal systems and the importance of using observation of contrasts and discriminations to build up understanding of systems. In the end, presaging his own radical pluralism to come, Naess seems to relax his early position on the importance and possibility of creating a metascience of science from the “far outside” and ultimately comes to view subjective and behavioral models as two different point-of-departure formulations in an indefinite plurality of equally valid approaches for a metascience of science. This refined perspective is taken up in Naess's 1965 article “Science as behavior” (in SWAN IX), which returns to the prospects and limitations of creating a behavioral metascience to study the scientific enterprise, but this time from the “near outside.”

At age twenty-four, after receiving his Ph.D. from the University of Oslo for his work on science as behavior, Naess returned to his interest in the problem of truth. A particular concern was the inadequacy of philosophers' intuitive methods for capturing how lay people conceived and used the term *true*. In 1937 and 1938 he developed and tested an empirical approach for using questionnaires and statistical analysis to investigate non-philosophers “commonsense” views on the notion of truth. He then related these notions to philosophers' theories of truth. Naess found an amazing diversity of views among the amateurs. He also found that their views, although typically devoid of philosophical pretensions, generally covered the views represented by professional philosophers. This work elicited substantial controversy, most of which came from philosophers who viewed it as undignified to use questionnaires and statistics to investigate one of the great problems of humanity. Naess's results were published as “*Truth as Conceived by Those Who Are Not Professional Philosophers* (1938). A summary of this work is presented in Naess's “Common Sense and Truth” (in SWAN VIII). Naess's continued application and refinement of these techniques would evolve into empirical semantics.

In 1937 Naess fortified his lifelong fascination with the arctic climate Hallingskarvet by building Tvergastein, his now-famous rustic and remote hut, at its base, a three-and-a-half-hour trek from the train station at Us-

SERIES EDITOR'S INTRODUCTION

tao set. He outfitted the hut with Rube Goldberg oil lamps that also served as stoves for warming tea and with an eclectic library of teach-yourself language manuals, Sanskrit-English dictionaries, astronomical and wildlife field guides, novels by Dostoyevsky and Ibsen, letters of Spinoza, and a complete philosophy library. Following his passion for amateur science he also created “institutes” of petrology, chemistry, zoology, hydrology, and botany at Tvergastein. Naess has written the bulk of his work at Tvergastein and spent the equivalent of about twelve of his ninety-two years living there. The enormous open views at Tvergastein afforded Naess the distance and perspective he so craved while insulating him from philosophic fashion and dogma. Here he had the luxury, freedom, and good fortune to pursue his own interests free from the banalities and distractions of academic life. After completing what is now Tvergastein’s main room, Naess went on to perform postdoctoral research at Berkeley (1938–39) with the pioneer of empirical psychology, E. C. Tolman. At Berkeley, he went from studying the behavior of rats faced with many possible alternatives to studying the behavior of the scientists studying the rats.

Naess returned to Oslo in 1939 to be appointed to the University of Oslo’s Chair of Philosophy at the age of twenty-seven. On April 9, 1940, German forces invaded Norway; it would remain under Nazi rule for the next five years. This was a harrowing time for academics throughout Europe. Arne tried to maintain his unruffledness, pouring himself into research and curricular reform initiatives intended to widen and expand the perspective of university undergraduates. He tried to stay at Tvergastein often, and this afforded him some peace and solace in a world of great tension. Before long, however, even he was drawn into the resistance movement. In the fall of 1943 he played a central role in foiling a Nazi attempt to deport University of Oslo students to concentration camps for “reeducation.” The University was subsequently closed and Naess became even more committed to the resistance movement and his research. By this time he had developed great admiration for Gandhi’s catalytic 1930 *satyāgraha* campaign, the march to Dandi in protest of the British salt tax. Naess was greatly impressed with Gandhi’s idea of trying to meet one’s opponent in a manner that would calm passions and facilitate truthful communication. He thought such an approach could have had a significant effect on quenching the Nazi expansion, *if* the necessary infrastructure to support *satyāgraha* had been created in European countries. After the war,

Naess used these insights in his efforts to bring together suspected torturers and the families of torture victims to gain a sense of closure on the fate of their loved ones—and to avoid having the “traitors” subjected to equally horrid persecution. In 1948 Naess was invited to be the scientific leader of a new UNESCO project created to explore ideological controversies between the East and the West. He was soon off to Paris again, this time to pursue his interest in using philosophy to address questions of social and political importance.

The Cold War was a tinderbox and two core ideological conflicts revolved around use of the terms *democracy* and *freedom*. Naess was asked to address both but countered that UNESCO's requirement that he deliver a report within one year made it essential for him to consider *democracy* first. His goals were to clarify what people mean when they use the term *democracy* and to understand the causes of ambiguity and confusion that result from its use. After an extensive literature review, which chronicled historical usage of the term, Naess and his assistant, Stein Rokkan, prepared a thirty-question survey that was distributed to almost 600 international experts in the fields of philosophy, law, history, political science, sociology, economics, communications, and logic. Naess used the roughly 100 replies to create an empirical study of “agreements” and “disagreements.” The study demonstrated *democracy's* richness, diversity, and multiplicity of meanings and thus undermined its misuse in both the East and the West. This incited detractors from every ideology, who roundly criticized the resulting report, *Democracy in a World of Tensions*, which according to Naess “was promptly sold out and never reprinted by UNESCO due to the politically dangerous character of its items.”²³ Naess's “Analytical Survey of Agreements and Disagreements,” along with two other pieces on ideological convictions and rationality, appears in SWAN IX.

The UNESCO democracy study was the first and last international, large-scale application of Naess's empirical semantics approach. He was originally interested in doing another study on “cultural diversity,” but neither this nor the “freedom” study came to fruition. Naess learned—much to his chagrin, and as his superiors had warned—that UNESCO was a place for writing reports; it was no place for conducting research. Naess's frustration with the UNESCO experience and his wanderlust for the perspective of mountains led him to daydream first, and then to “pursue non-essentials”:²⁴

SERIES EDITOR'S INTRODUCTION

The arguments against abandoning the imaginary joys of the Himalayas for an actual expedition seemed strong to me, and so they still do. But in the autumn of 1948 the longing for the mountains pushed aside all sensible considerations. For the first time since I was twelve years old, I had to do without a summer holiday in the mountains. The safety valve guarding one against exaggerated climbing expeditions was thus removed. Added to this came the great disappointment in my own work. Lured by UNESCO's plans of philosophical research into international ideological conflicts, I had been tied up in Paris for nine months. Such large-scale extravagant schemes prove, however, impracticable. Too much nationalism and too little belief in research prevented UNESCO from getting the number of nations to subscribe to such long term schemes. By the way of compensation, I indulged at night in delightful trips to the Alps. As the situation got worse, this was, however, not sufficient compensation; the material was exhausted. Then my fantasies took me to the Caucasus. Later I had to go all the way to Persia, Afghanistan, Hindu Kush and India, and so I was committed.²⁵

Although Naess's research interests and total view continued to evolve after 1953, the general philosophical approach of the mature Naess, outlined at the beginning of this essay, was basically in place. Naess has described his philosophical work as falling into four periods or phases. From the mid-1930s until about 1940, he focused on philosophy of science. Then until about 1953, he concentrated on empirical semantics. A short period, surrounding the publication in 1968 of his major work on the zetetic scepticism of Pyrrho, ends when, at the pinnacle of his philosophical career, he sought early retirement in 1969 to devote himself more fully to ecological issues and activism. Naess has commented that this effort to be more actively engaged in social and political conflicts reflects his desire "to live rather than function." This view adequately reflects coarse, general trends, but it fails to do justice to Naess's philosophical approach, which has him mine a larger range of topics and return to them in a helical fashion throughout his life. I would rather describe his work as falling into thematic areas that were picked up, sometimes put on ice, but returned to periodically throughout his life. Although I concur that the period after his formal retirement can be seen as emphasizing ecological philosophy and activism, the two decades between 1960 and 1980 also represent a period of considerable productivity on conventional academic philosophical topics. It was in those decades that Naess produced important work, especially, on

scientific and cultural pluralism, Gandhi and Spinoza scholarship, history of philosophy and philosophy education, and normative systems theory. He has written on a wide range of important philosophical topics even into the 1990s and beyond, during which time he produced, among other works, his *Life's Philosophy* (2002; coauthored with Per Ingvar Haukeland), introductions to the philosophy of Gandhi (2000) and Spinoza (1999), and *Introduction to General Relativity and Its Mathematics* (1998; coauthored with Øyvind Grøn).²⁶ An adequate sketch of Naess's subsequent research interests and philosophical development can be gleaned from the following brief discussion of the volumes in the *Selected Works* and the discussion, at the end, of how his earlier work figures into the evolution and exegesis of deep ecology.

Naess's best-known philosophical work is likely *Interpretation and Preciseness*, published in 1953 (SWAN I). It is an attempt to convince the world of analytical philosophy about the types of approaches that are necessary, from the standpoint of a radical empiricist, to adequately interpret terms and point-of-departure statements (T_0 statements), given the manifold of plausible interpretations. It highlights the role and potential of experience in relation to intuition and reflection by requiring that every direct or implied hypothesis regarding the actual use of terms, phrases, or sentences be testable. In addition, it responds to the ostensibly antiphilosophical sentiment in *Erkenntnis* by clarifying the function of and relationship between point-of-departure statements and precizations. In Naess's semantics, the most general statements, T_0 statements (words or sentences), are phrased in ordinary language and are intended to be philosophically neutral. T_0 statements serve as points of departure for investigations of possible interpretations. When a new interpretation of an expression eliminates some of the ambiguity of a preceding interpretation, without adding any new ambiguity, it is said to be a "precization." Thus, a sentence T_1 is more precise than a sentence T_0 when every plausible interpretation of T_1 is also a plausible interpretation of T_0 but at least one plausible interpretation of T_0 is not a plausible interpretation of T_1 . This process of using successive differentiation to better understand people's interpretations of terms, phrases, or sentences can go on almost ad infinitum; it is limited only by time, resources, imagination, and willing test subjects. With this process, however, Naess has created a formal approach for classifying different statements (interpretations) based on users' "depth of intention," the point at which they no longer, explicitly or implicitly, accept or embrace higher levels of precization. A focal point is

SERIES EDITOR'S INTRODUCTION

Naess's approach of directly employing surveys to explore systematically and empirically the meanings of terms, phrases, or sentences based on their occurrences. Naess also created a formal procedure for comparing occurrences, both interpersonal and intrapersonal, that involves performing tests for different forms of synonymy. Naess has applied his empirical semantics approach to explore the meanings of "truth," "democracy," "it is the case," "certain," "perfectly certain," and "extremely probable" (see SWAN VIII for additional details on and applications of empirical semantics).

In *Scepticism* (SWAN II), published in 1968, Naess takes on the generally accepted position that scepticism, if widely embraced, leads to the intuitively false conclusion that we cannot know anything. Naess explores the variety of historical interpretations of scepticism in light of Sextus Empiricus's outline of Pyrrhonian scepticism. Three categories of philosophical positions on the question of truth are considered: Dogmatists claim at least one truth, Academicians negate the possibility of finding any truths, and Pyrrhonists neither assert that they have found any truths nor assert the impossibility of finding one. Naess takes a sympathetic view of this last group, arguing that this form of zeteticism can represent both a viable philosophical position and a way of life that supports positive mental health. What ultimately sets this position apart is not that supporters are fundamentally opposed to making acts of assertion, to stating that "something is the case," but that they do not make such assertions with the conviction of truth. Naess also uses empirical semantics to demonstrate support for this position on rational and epistemological grounds. Distinguishing between one's philosophical view and the necessity of firm, socially responsible action in everyday life, he also responds to the common notion that this radical nondogmatism generally leads to paralysis of action. In the end, Naess argues that adopting this updated view of Pyrrhonic scepticism could lead to quite the opposite, a more open-minded approach to philosophy and life. Further elaborations on particular aspects of Naess's Pyrrhonism along with a response to Rescher's reappraisal of scepticism appear in SWAN VIII.

Which World Is the Real One? (SWAN III), which was first published in 1969 and revised in 1982, is, in part, an attempt to reinvigorate appreciation and study of the broad variety of philosophical outlooks and total views that exist in Chinese, Indian, Greek, Western, comparative, and recent philosophy. It makes use of Naess's empirical semantics, developed in *Interpretation*

and Preciseness, to argue that it is an illusion to assert that combined scientific and philosophical or “purely” philosophical syntheses of such total views can exist. Naess argues that the results of science cannot be integrated into any single world picture, in part because such attempts at synthesis are necessarily fragmentary and because valid multiplicities of syntheses exist. He also takes up the question of the comparability of total views. Such comparisons, although important, are inevitably shaky because, despite admirable aspirations for standing back to obtain a meta-perspective, real people can never totally throw off their own total views; regardless of how explicit those views may be or of how conscious of them their holders are, biases are unavoidable. We always have our own perspective to contend with. For Naess the inevitable conclusion is that pluralism is inescapable and nothing to lament. He combines these points of view with a discussion of cultural anthropology to argue for the critical importance of supporting the flourishing of rich cultural diversity. Additional articles elaborating themes related to the significance of maintaining cultural diversity and its relationship to ecological sustainability appear in SWAN X.

In *The Pluralist and Possibilist Aspect of the Scientific Enterprise* (SWAN IV), published in 1972, Naess suggests that scientific theories must be understood in the wider context of the plural rationalities from which they spring. Science is not autonomous. Nor can it be seen justifiably as arising independently from the general enterprise of building philosophical systems. Furthermore, the relationship of models to reality is always indirect. This volume should be seen as an effort to erode the popular misconception of science as infallible and a viable surrogate for religion, not as an attempt to build a unified theory of science within one system, which Naess had long since rejected. Because no theory can ever be either fully verified or falsified, there exists a significant freedom of choice in both modes of exploration and theories that one can tentatively adopt. The notion of “fundamental theories” is immediately called into question. As the undemonstrated (and often undemonstrable) assumptions upon which theories rest are changed, a huge multiplicity of possibilities for future theory development arises, thus possibly helping to inspire a renewed enthusiasm in science by broadening our concept of rationality and restoring the role of imagination. Articles extending or elaborating on the ideas in *The Pluralist and Possibilist Aspect of the Scientific Enterprise* appear in SWAN IX.

Naess's third book on Gandhi, *Gandhi and Group Conflict* (SWAN V),

SERIES EDITOR'S INTRODUCTION

was published in 1974. This book develops an intellectually rigorous presentation of the theory of *satyāgraha*—the way of militant nonviolent resistance—as a strategy for conflict resolution. This work is a paradigmatic example of Naess's approach to research and writing. As the eminent Norwegian social scientist and peace researcher Johan Galtung has suggested, Naess's 1955 *Gandhi's Politiske Etikk* (Gandhi's political ethics)—with Galtung—and his 1965 *Gandhi and the Nuclear Age*, along with his articles that analyze or extend on Gandhi's work (see SWAN IX and X), act as exercises or drafts for this, his major work on Gandhi.²⁷ Using Gandhi's own recorded accounts, Naess explores the norms and hypotheses tacitly employed by Gandhi in his nonviolent campaigns and then uses these to create the first philosophical and logical systematization of Gandhi's approach to militant nonviolence. A careful investigation of Gandhi's two ultimate norms (as interpreted by Naess), "Seek complete self-realization" and "Seek truth," and his belief in *advaita* (nonduality), along with a consideration of their parallels to Spinoza's unity thesis, will reveal interesting insights into Naess own characterization and use of "Self-realization!" as the single ultimate norm of his Ecosophy T. Naess also considers Gandhi's approach to nonviolent conflict resolution in light of contemporary reactions against the use of nonviolence by Frantz Fanon, Malcolm X, Stokley Carmichael, C. V. Hamilton, and Sartre. He then examines Gandhi's ideas and intentions regarding group conflict in light of the ideas and intentions underlying other modern philosophies of conflict, including those of Luther, Nietzsche, Tolstoy, and Jaspers.

In *Freedom, Emotion, and Self-Subsistence: The Structure of a Central Part of Spinoza's Ethics* (SWAN VI), Naess uses symbolic logic to present a formalization and partial reconstruction of a small but important part of the *Ethics*. Spinoza's system is embedded in the seventeenth century and expressed in Medieval Latin. Two of Naess's goals are to bring empirical analysis to bear in trying to interpret and update Spinoza's system and to make Spinoza's insights more accessible and relevant to contemporary readers. To perform his reconstruction, Naess draws heavily on a small book he produced in 1962, *Equivalent Terms and Notions in Spinoza's Ethics*, which lists and discusses 243 equivalences that are directly asserted or suggested by Spinoza in the *Ethics*, according to Naess.²⁸ Accepting the transitivity of the equivalence relations as a general rule, Naess argues that a vast array of structural relations can be elucidated (many of these are often only suggested or implicitly asserted by

Spinoza). One of Naess's key conclusions is that every living thing is to some extent "in itself" and to some extent "in something else" due to the presumed gestalt nature of reality. Another is that the terms *substance*, *attribute*, *God*, *mode*, and *Nature* are "expendable"; Spinoza's basic nondualism is made clearer by Naess. A third conclusion is that *to be active* and *to understand* cannot be systematically distinguished in the *Ethics*. This notion, which has important implications for philosophy of science, is also embedded in Naess's conclusion in *Erkenntnis* that knowledge is cognition—the content of knowledge and the activity of research cannot be cleanly separated. Naess uses his analysis to explicate three main themes of Spinoza's system: the importance of a notion of uncoerced freedom (not coerced by externals), the importance of developing and acting on strong emotions to make progress in achieving higher levels of freedom, and the importance of joy that activates the complete person (as opposed to joy that simply activates part of the body or the soul). By clarifying the semantic structure of a central part of the *Ethics* with his own logical structure, Naess explains that there exists a wide variety of possible interpretations of the contents of the *Ethics*. Articles on Spinoza's determinism and its relationship to freedom, Spinoza and Māhāyana Buddhism, "Spinoza's Finite God," and other Spinoza-related topics appear in SWAN IX. Articles that explore Spinoza as an inspiration for deep ecology appear in SWAN X.

The English translation of *Communication and Argument: Elements of Applied Semantics* (SWAN VII), which was first published in 1966, is largely a popularization of the central ideas in *Interpretation and Preciseness*. The English edition is a somewhat watered-down version (no exercises) of the Norwegian edition that from 1941 to 1969 was used by nearly 100,000 university students in the *examen philosophicum*. Its purpose, to quote the *Times Literary Supplement*, is " . . .to teach people in a democratic society to think clearly, coherently, and above all responsibly." Naess's hope is that teachers use controversial examples from current events—the more emotional the better—to confront students with their own confusion and encourage them to strive for higher levels of depth of intention. The final chapter outlines six "Gandhian" rules of effective discussion, which emphasize avoiding six forms of "irrelevance in discussion."

The first two volumes of selected papers (SWAN VIII and IX) contain important material that is not covered by the preceding volumes, material that complements them, or material that builds on or reevaluates positions

SERIES EDITOR'S INTRODUCTION

taken earlier. Volume VIII includes sections on "Empirical Semantics and 'Truth,'" "Zeteticism," "Empiricism, Possibilism, and Pluralism," and "Metaphysics, Morals, and Gestalt Ontology." Volume IX includes sections on "Democracy, Ideology, and Rationality," "Philosophy of Science," "The Philosophy of Peace, Gandhian Ethics, and Communication," "Spinoza," and "Philosophical Development, Environment, and Education" (which includes an autobiographical article describing key influences in Naess's philosophical evolution, "How My Philosophy Seemed to Develop" and an interview, "Deep Ecology and Education"). A number of the especially significant articles have already been referred to, where relevant, in the discussion of Naess's philosophical evolution; other articles are discussed in the notes.

Today, Naess is, perhaps, best known for his "deep ecology" writings, the topic of *Deep Ecology of Wisdom* (SWAN X). This work began with a short unpublished paper written in 1965, "Nature ebbing out" (in SWAN X), and continues to this day. As the primary architect of deep ecology, Naess has more than seventy-five published articles and book chapters and more than sixty unpublished pieces on this topic. His only book-length discussion of deep ecology began with a short mimeograph, *Økologi og Filosofi* (Ecology and philosophy), published in 1971. The fifth revision and expansion of this initial work resulted in the 1976 classic, *Økologi, Samfunn og Livsstil* (Ecology, community, and lifestyle), which has been translated into Swedish, English (1989), Italian, Japanese, and Czech. This book has not been included in the *Selected Works* because it is widely available and currently in print.

Volume X is the first comprehensive collection of Naess's work on deep ecology—it includes a broad array of articles on its history, influences, theory, development, practice, and prospects. This volume shows how deep ecology represents the integration and culmination of Naess's lifelong interests in philosophy, social research, activism, science, and nature. It demonstrates how Naess, in his explication and elaboration of deep ecology, draws extensively from both his life experience and his research on empirical semantics, scientific and cultural pluralism, Pyrrhonic scepticism, Spinozistic nondualism and activeness in relation to problems, gestalt ontology, normative systems theory, total views, and Gandhi's concepts of self-realization and nonviolent communication. Volume X also shows how Naess's approach to deep ecology has unfolded over time, with substantial emendation, in part as a response to the worsening ecological crisis, in part to answer criticisms that deep ecology was turning into a cult or religion,

and in part to address the considerable confusion and controversy that arose from his use of provocative terminology and philosophical vagueness.

Ever since he coined the term *deep ecology* with his now famous paper "The shallow and the deep, long-range ecology movement: A summary," (in SWAN X) given at the 1972 Third World Future Conference in Bucharest, Naess's central concern has been to use philosophy and philosophical thinking to help humans overcome the ecological crisis and, ultimately, to restore the Earth to a state of rich and flourishing biological and cultural diversity (see volume X). A basic premise is that some ethical norms, particularly those grounded in spontaneous experience, can be tentatively accepted as objectively valid. An example for Naess would be the statement that "Every living being has an equal right to live and flourish, *in principle*." This statement in no way denies that maintaining our existence necessitates killing living beings. Another key premise is that the human potential for caring is not static or limited—it can be both extended and deepened. The ecological crisis is embedded in an ecocultural crisis. Its resolution will necessitate cooperation and collaboration among the peace, social justice, and ecology movements.

Naess does not see himself as "inventing" deep ecology. Rather, he gave a name and a philosophical framework to a minority tradition, a nascent social movement that has been with humanity since at least Buddha, Chuang Tzu, Saint Francis of Assisi, Thoreau, John Muir, and Aldo Leopold, and is epitomized by Marjory Stoneman Douglas's 1947 *Everglades: River of Grass* and subsequent crusade to save the Everglades.²⁹ This movement finally came of age in the contemporary era after Rachel Carson's *Silent Spring*. Naess's work on "deep ecology" can be subdivided into three main thematic areas.³⁰

What I refer to as Naess's deep ecology approach (deep ecology as an ecophilosophical approach) represents his contributions to deep ecology theory—it is essentially an outline of a general philosophy of life, which draws considerable inspiration from Gandhi and Spinoza. The focal points are encouraging ultimate beliefs that support our capacity to identify with all living beings and Naess's general, pluralistic, normative systems-based strategy for assisting individuals in the process of weaving their ultimate beliefs, descriptive and prescriptive premises about the world, ecological science, and philosophy into systematic conceptual structures for relating to the world—ecologically inspired *total views* or *ecosophies*.

His work characterizing and supporting deep ecology as an international, grassroots social and political movement, along with his work enter-

SERIES EDITOR'S INTRODUCTION

ing into the fray, addressing conflicts, implications, and practical applications of the theory, falls into the realm of contributions to the “deep ecology movement.” Supporters of the deep ecology movement are not united by a commitment to deep ecology as an academic ecophilosophy (which they may not be familiar with or embrace), but by their willingness to endorse the eight-point deep ecology platform, prepared by Naess and Sessions in 1984.³¹ Finally, work discussing his personal systematization of a deep ecological total view falls into the realm of “Ecosophy T.”

Naess coined the terms *deep ecology* and *shallow ecology* in 1972 to juxtapose what he regarded as two radically different approaches for problematizing (*Problematisieren*) and responding to the ecological crisis. In proposing the deep/shallow contrast, he made a technical semantic distinction directed at our level of problematizing—the extent to which we can, and do, coherently and consistently trace our views, practices, and actions back to our ultimate beliefs or bedrock assumptions. Naess starts with a premise, which he has investigated empirically, that at the level of their ultimate beliefs, people generally identify with and appreciate nature. He then uses this to argue that many regrettable environmental decisions are made in a state of “philosophical stupor,” in which narrow concerns are confused with, and then substituted for, more fundamental ones.

The “shallow,” currently more influential approach to environmentalism is identified with treating the symptoms of the ecological crisis, such as pollution and resource degradation. This reform-oriented approach is grounded in technological optimism, economic growth, and scientific management, not in ultimate premises that plumb the relationship between people and nature. It thus ultimately fails to address the philosophical, social, and political roots of the ecocultural crisis.

The “deep” approach, on the other hand, while in no way discounting the exigency of addressing pollution and resource degradation, adopts a broader, long-term, more sceptical stance. Doubtful about technological optimism, critical of limitless economic growth, and decidedly against valuing nature in purely instrumental terms, it asks if the shallow approach’s proposed solutions take into consideration the nature of reality and the complexity of the problems its adherents hope to rectify. Stressing the importance of addressing the fundamental roots and coevolving causes of the ecological crisis, deep ecology posits that along with humans’ special capacities for reason and moral consciousness come special responsibilities,

particularly in relation to the flourishing of nonhuman life and the ecocultural sustainability of the planet.

The deep ecology approach calls for expanding our sphere of concern to all living beings—charismatic or dull, gargantuan or tiny, sentient or not. It acknowledges that every living being has value in itself and views the flourishing of nature and culture as fundamentally intertwined—as part of one reality. This *wide-identification* is characterized by the perception that all life is interdependent; common goals bind all living beings to the life process. In Naess's view one can arrive at wide-identification by drawing on a broad diversity of philosophical or religious ultimate premises, with roots ranging from Christian Stewardship to the Gaia Hypothesis to Naess's own ontologically inspired "Self-realization!" In its most expansive form, wide-identification is the intuition that nature's interests and our own coincide, as with Naess's "Self-realization!"—something akin to a blending of the Hindu *ātman* with a biospherical Pareto-optimality principle. Simply stated, this principle asserts that the increased realization of any individual or species rests on advancing (or at least not hindering) the realization potential of all other individuals or species.

By juxtaposing these two, almost caricatured perspectives, Naess employs a technique of Gandhian nonviolent communication designed to confront core disagreements. The central premise is that society's potential to overcome the ecological crisis rests on guiding discussion and debate to its root causes. One of the primary root causes, Naess asserts, is the widespread disjunction between people's core beliefs and their actions. People, in general, neither comprehend how their practices and everyday lifestyle choices harm the environment, nor recognize how these consequences may be in direct conflict with their core beliefs—this is the primary weakness of the shallow approach. A crucial, underlying hypothesis of the deep approach is that teasing out the presumed inconsistencies between an individual's actions and his or her fundamental beliefs, while possibly engendering serious ancillary conflict along the way, will ultimately generate progress toward ecocultural sustainability.

Naess contends, as I have pointed out earlier, that humans act as if we have total views whether or not we make such structures explicit. Because our decisions regarding society and nature are guided by our total views, Naess maintains, we *should* attempt to articulate them. By making these structures explicit, we expand both our opportunities for fruitful debate and

SERIES EDITOR'S INTRODUCTION

interchange and our possibilities for creating policies that are consistent with our collective ultimate beliefs. This focus on praxis (responsibility and action) separates the deep ecology approach from more descriptive inquiries into environmental philosophy that focus on axiological questions, such as extending "rights" to certain nonhuman life-forms or grading intrinsic value. The ontologically inspired deep ecology approach attempts to counter the perception of fundamental people/environment and spiritual/physical cleavages. Its primary strategy for overcoming the ecological crisis is to help individuals avoid pseudo-rational thinking.

In relating this notion of persistently asking deeper questions to the ecological crisis, Naess broadens his concept of "depth." In the context of deep ecology as an ecophilosophical approach, depth refers to both the general level of problematizing we employ in seeking out the underlying, co-evolving causes of the ecocultural crisis and the extent of our willingness to consider an expansive array of social and policy responses, even if they necessitate changes that constitute a radical departure from the status quo. Rather than calling for a new environmental ethic or a radical change in fundamental values, Naess's approach to ecophilosophy centers on transforming practice and policy by challenging us to develop more thoroughly reasoned, consistent, and ecologically inspired total views. This work represents a culmination of his effort to integrate reason and emotion. He has created the foundation for a new and promising human/nature relationship that positions humans as plain citizens with special abilities and unique responsibilities and nature as mentor, measure, and partner rather than servant. The current state of global ecological unsustainability has made Naess state that he is optimistic about the twenty-second century but pessimistic about the twenty-first; humans have a long way to go.

Deep ecology has been criticized for being too critical of pragmatic efforts to address acute environmental problems. It has also been accused of being inherently fascist, antihumanist, antifeminist, and against having indigenous peoples share wilderness areas with nonhuman life-forms.³² As the articles in volume X will show, none of these criticisms are compatible with a sophisticated reading of Naess's writings on deep ecology as an ecophilosophical approach. This is not to suggest that deep ecology as an ecophilosophical approach has clear answers. In inspiring many people to reconsider their value priorities and more consistently relate them to their lifestyles and everyday actions, deep ecology opens more questions than it answers. Three

key issues for future research loom on the horizon. First, how can society motivate value priorities for ecological sustainability when individuals do not, on first principles, embrace wide-identification? Second, does taking a deep ecological perspective over a shallow ecological perspective actually result in better policy—policies that lead to long-term protection of cultural and biological diversity, using democratic, noncoercive, and ethically unobjectionable means? Third, how can deep ecology help resolve conflicts in environmental decision making when those conflicts result not from pseudorational thinking but from genuine value conflicts?

Throughout this essay, I have tried to show how Naess's life of rich and varied spontaneous experiences and internal tensions have shaped not only who he is as a person, but also who he is as a philosopher. Viewed separately, Naess's contributions to academic philosophy, social research, and ecological philosophy and activism can appear discordant, dilettantish, and incoherent. When, through careful study of his helical progression, his philosophical and personal maturation, the pattern of the whole unexpectedly reveals itself as a unity, the whole suddenly becomes much more than the simple sum of individual books and articles. With the distance of a meta-perspective, Naess's collective philosophical contributions can be seen as a mosaic—as a superordinate gestalt, in some sense, as a rich and inspiring, but inevitably fragmentary total view. Naess has breathed life back into the study of philosophy by turning its study back to life. With his cultivation of a meta-perspective, a whole, new (old) approach to philosophy and way of seeing the world emerges. This richly patterned mosaic, by encouraging us to celebrate our freedom and affirm life, can help us to reshape our relationship to each other and the Earth in new and promising ways.

Conclusion

It was only as a professor that I became aware of the difficulties of suppressing the significance of the development of feelings in human affairs while at the same time worshipping reason. Both are constantly needed.

Arne Naess, *Life's Philosophy*

The ten volumes of this series (along with a subsequent volume of conversations between Naess and myself on deep ecology and his philosophy)

SERIES EDITOR'S INTRODUCTION

make available for the first time access to the breadth and depth of Naess's philosophical thought. Efforts to judge the significance of Naess's philosophical oeuvre—assertions made in the first sentence of this essay—can now be taken up on an informed basis. When embarking on this process, it may prove beneficial to reflect on Henry Adams's insight on the fundamental limitations of communication, and especially the limits of communicating one's fragmentary total view, "No one means all he says, and yet very few say all they mean, for words are slippery and thought is viscous."³³ Spinoza ends the *Ethics* with the following remark: *Sed omnia praeclara tam difficilia, quam rara sunt* ("But all very clear things are as difficult as rare").

In *The Radical Spinoza*, Wienpahl translates the phrase more literally than usual, rendering *praeclara* as "very clear" rather than the typical "excellent."³⁴ The quest for clarity is painful and difficult as well as amaranthine. The alternative, however, is to abandon joy and freedom and thus meaning. This is the essence of Naess's distinction between being an *academic philosopher* and being a *philosopher of life*, between merely *functioning* and *living*. Drawing inspiration from Spinoza, Naess has cultivated a practice of both integrating reason and emotion *and* transforming negative emotions into positive ones. His challenge is before us and the frontier is long—the choice, however, is ours.

Editorial Approach

Naess has always written books as if they were exercises for himself, tentative formulations that chronicled his views at that very second but were always subject to change. As I indicated previously, many of the prior editions of his books were poorly edited and sparsely documented. Existing bibliographies were incomplete, and indexes (in the rare cases in which they existed) were always inadequate. Quotations were often transcribed incorrectly and ill-referenced. In addition, the breadth of his work was enormous and sometimes repetitive. Arriving at a plan for a representative *Selected Works* that would have a consistent format and design was no easy task.

All the selections for the *Selected Works* were made in close consultation with Naess. I would prepare recommendations from my master bibliography file and then, whenever we disagreed, we would discuss the pros and cons of the piece and whether it was appropriate for inclusion (this ap-

proach proved particularly helpful when we reached the *Selected Papers* volumes). We immediately made a decision to exclude works that were widely available and currently in print. Other important works, such as his dissertation, and his major work on lay people's conception of truth, his work on the semantics of democracy and ideological controversy, and his contributions to history of philosophy were more difficult to exclude, but the nature of the project as a selected works demanded such tough choices. I was encouraged by the fact that Naess often published articles that summarized or updated earlier works. In the end, I was able to reflect a significant portion of the ideas and concepts in these excluded works by including articles of that type in one of the three *Selected Papers* volumes.

The details of editing proved more complex. Much to my chagrin, I very humbly learned how much work goes into a project of this scale and complexity. We decided early on that the level of editing required to bring the prior publications up to the high standards of contemporary academic philosophical publishing would necessitate revised editions. We also decided that since we were preparing revised editions and Naess was alive and could review the work, we would make the role of the editor invisible and not include tedious footnotes chronicling all the changes, however significant they might be. The historical significance, intricacy, and sheer magnitude of *Interpretation and Preciseness* (SWAN I) warranted special consideration. For these reasons, we decided that it would be best to prepare only an edited version for this volume and not attempt a complete revision as with the other volumes. In the early stages of the project Naess and I worked together closely, intimately. In my effort to eliminate errors and to enhance readability, flow, and clarity of argument, I brought Naess question after tedious question when I first embarked on the project (particularly when I was in Norway as a Fulbright Scholar in 1996). After working through several manuscripts, Naess decided to place the remainder of the responsibility for revising and editing the manuscripts in my hands.

We have made our best effort to reconcile inconsistencies, make corrections, and chase down incomplete bibliographic references (in most cases no bibliographies existed for the original works). I regret, however, that some imperfections remain. I am also responsible for any new errors that have been introduced—their existence, unfortunately, is unavoidable. I am, however, heartened by a conversation I had with Naess midway through the project, after he had reviewed several drafts of revised manu-

SERIES EDITOR'S INTRODUCTION

scripts. He commented that at least 90 percent of my revisions resulted in improvement and that no significant misinterpretations had been introduced. Given the nature and complexity of this project, that sounded like odds I could live with.

Acknowledgments

A project of this magnitude, by its very nature, represents the labor and love of an entire community. It could never have gotten off the ground, much less been completed, without a fantastic and deeply committed team. I have been blessed by the opportunity to work with, learn from, and receive guidance and support from so many talented friends and colleagues. It's been a wild ride; I owe you all a tremendous debt of gratitude.

First, the inspiration for the *Selected Works* and the majority of its financial support are due to the foresight and generosity of "Miracle Doug," Douglas Tompkins, president of the Foundation for Deep Ecology (FDE). Thanks for your vision, Doug. Quincey Tompkins Imhoff, former executive director of the Foundation (and current vice president of the board), also deserves recognition for her tremendous support during the early years of the project, as do program directors Jerry Mander and John Davis. Special thanks also go to Sharon Donovan, the Foundation's publishing manager, who in the project's final years has guided it through a long and sometimes circuitous path to completion. The Foundation has also always had an amazingly gifted and dedicated staff. At one point or another, many of its staff had a hand in helping this project along—offering assistance at a key point, a kind word, inspiration, or simply good cheer and a smile. Thank you, Denise Wilson, Debi Barker, Esther Li, Lizzie Udwin, Julie Lindow, Miyo Sakashita, and Emily Lydgate.

I was also supported by the Fulbright Foundation with a senior research/teaching fellowship at the University of Oslo's Centre for Development and the Environment and Institute of Philosophy in 1996. Additional support came from Western Michigan University. Special thanks go to WMU's dean of the College of Arts and Sciences, Leonard Ginsberg, and to my chair, Thomas Bailey. My colleagues at Western Michigan University also deserve thanks for their tolerance and succor while I focused all my available energies on this project. I am grateful for their flexibility and generous support. Wil Emmert, one of WMU's Research and

SERIES EDITOR'S INTRODUCTION

Program officers, also deserves a great thanks for his patience and skillful assistance.

The project has been blessed with a distinguished advisory board—Robert S. Cohen, Bill Devall, Alan Drengson, Ingemund Gullvåg (deceased), Per Ingvar Haukeland, Kit-Fai Naess, Nicolas Rescher, George Sessions, Michael Soulé, Douglas Tompkins, and Jon Wetleson. All of the advisers offered significant assistance in one form or another. Bob Cohen graciously shared his expertise and offered invaluable advice, encouragement, and support throughout the project. Bill Devall gave encouragement and helped bring volume X to completion by coauthoring its preface. George Sessions offered advice on the selections for volume X, provided guidance, and carefully reviewed a draft of this introduction. His suggestions greatly improved its flow and clarity. Kit-Fai Naess's tremendous moral support and great assistance in locating obscure documents and preparing bibliographies were invaluable.

Alan Drengson's contribution as a project adviser and in the project's final year as Associate Editor deserves special mention. At a crucial time, when the project was stalled in its later stages, Alan stepped up to the plate and played a key role in helping shepherd the project to completion. In particular, he took over most of the day-to-day project-coordination responsibilities for the final year of the project. He reviewed the copyedited manuscripts for volumes I, VIII, IX, and X, oversaw preparation of the author's prefaces to each volume and the editors' prefaces to volumes VIII, IX, and X, and reviewed the final manuscript proofs. This was not an easy task. I owe Alan a great debt for his fortitude, commitment, and generosity. For his contribution to the difficult and taxing responsibility of overseeing the final preparation of volume I, he has been credited as its sole editor.

I am lucky to have been supported by two astonishingly capable, committed, and patient project assistants. Kim Zetter played a critical role in getting the project off the ground and keeping it on schedule for the first three years. Later, Barbara Pijan helped steer the project back on track and over some awkward obstacles after it had run off course. Their talent and dedication played a major role in bringing to life the books before you. Thank you, Kim and Barbara, for your stalwart devotion to the project.

The beautiful and elegant design of the series is the work of Tomatsu Yagi and his nephew Akira Yagi. Ralph Fowler played a significant role in executing the Yagis' design and by filling in any missing gaps. Ralph also

SERIES EDITOR'S INTRODUCTION

performed the typesetting for volumes II–VII. The skillful and efficient crew at BookMatters performed the remainder of the typesetting. Katherine Silver handled the Brobdingnagian task of project management on volumes I and VIII–X and the last crucial stages of the project with aplomb, attention to detail, and fortitude.

The bulk of the project's copyediting was performed by the meticulous and supertalented Anne C. Collins, Ph.D., copyeditor extraordinaire. Additional copyediting was provided by Mary Anne Stewart and Kathy Walker. Indexing was performed by the immensely competent Nancy Mulvaney of Bayside Indexing Service, Julie Shawvan, and Leonard S. Rosenbaum. Proofreading was provided by Carrie Pickett.

Ingemund Gullvåg translated *Which World Is the Real One?* Iver Ørstavik provided the translation of "Experts' views on the inherent value of nature." The original editions of Naess's texts were keyed or scanned by the able and efficient crew at AgAccess—David Katz, Karen van Eppen, Jacob Katz, Rachna Boon, and Tim Rice. Additional keying of articles for the *Selected Papers* volumes was provided by Nancy Ropecka and Jane Drengson. Barbara Pijan, d Jones, Tony Hainault, and Debbie Reid deserve thanks for their careful and thorough transcribing of more than thirty-five hours of discussions with Arne Naess. Thanks are also owed to Tim Quick for his help with bibliographic research for volumes I and VIII–X, and to Kelly McKernan for assisting Alan with photocopying and faxing. In addition, a special thanks goes to Robert P. Goldman, Sarah Kailath Professor of Sanskrit and Indian Studies at the University of California Berkeley, for generously and graciously offering assistance on contemporary Sanskrit and Hindi terms.

I am grateful to the dedicated and very patient staff at Kluwer Academic Publishing. I am sad that our original editor, the immensely talented Annie Kuipers, who first recognized the importance of this project, did not live to see it come to print. Stephanie Harmon, Annie's replacement, worked closely with me on editorial matters and on finding high-quality recycled paper, cloth, foil, and other materials that meet the strict environmental considerations of FDE. In the final five years, the able and gifted Charles Erkelens was our editor.

Additional advice and moral support were provided by colleagues, friends, and family: Aimee Carroll, Kirsten Coyne, Paul Craig, Neal Goodwin, Byron Hahn, Ladislav Hanka, Alastair Hannay, Anna Leidberg-

SERIES EDITOR'S INTRODUCTION

Miron, Danny Moses, Richard Norgaard, Max Oelschlaeger, Brian Recht, Stephanie Sarvar, Ed Saxon, Geir Michael Sommerhein, Petter Sorum, and Kristin Walstad. Thanks for your efforts to coax me out of the cave.

Special thanks go to d and Reuben for their forbearance and succor. Someday, all too soon, Reuben will recognize that the invisible “work fairies” that were constantly pulling me back to my office don’t actually exist. I can’t wait.

Most of all, thanks to Arne Naess for placing his trust in me—it’s been a gift, something like an extended trudge up to Tvergastein, but without the fresh air and perspective. Taking on this project has been somewhat like receiving Pandora’s box as a present—all sorts of ills and plagues reared their heads along the way. I often felt that I was on a never-ending climbing descent in the night. I was always wondering about rappelling off my rope into the abyss.

The SWAN has taken flight, and I have landed on firm ground—I think? In all seriousness, I learned invaluable lessons. The more I worked through Arne’s writings, the more open-minded and optimistic I became. I found myself cultivating perspective and looking at the problems and challenges before me with fresh insights. I also found myself responding with more grace and equanimity in my efforts to counteract the numbing effects of contemporary society.

It is strange and ironic, however, that in being the series editor for the *Selected Works* of the father of deep ecology I spent so much time inside, chained to a desk. But this is part of the paradox of working with Arne Naess. I am reminded of one of my favorite poems—Gary Snyder’s “Axe Handles.” The last few lines read:

Pound was an Axe,
Chen was an axe, I am an axe,
And my son a handle, soon
To be shaping again, model
And tool, craft of culture,
How we go on.

And then it makes sense.

Harold Glasser
2004

Notes

1. In writing this essay, I found myself drawing on more than twelve years of friendship with Arne Naess. A simple bibliography could not do justice to describing how this subtle and multilayered gestalt has been formed. My perception of Naess and his work has been shaped by more than thirty-five hours of transcribed conversations between us, countless other conversations, letters, scraps of paper, e-mails, and Arne's copious annotations in my own books and articles. Camping trips, bouldering, hikes, and cross-country skis have also helped inform my understanding of Arne Naess the fiercely competitive, playful, elfin trickster, who springs to life in nature. I have benefited from three extended visits to Norway, including a Senior Fulbright at the University of Oslo's Centre for Development and the Environment and Institute of Philosophy in 1996. I have also spent other stimulating periods of time with Arne in Svalbaard, England, California, and the deserts of Arizona and Nevada. Finally, and probably most important, I have been inspired and forever changed by my own reading and editing of his work. In this regard, both previously published and unpublished materials have been influential in forming my own perspective on Arne Naess the philosopher. One key published source has been Naess's "How my philosophy seemed to develop," in *Philosophers on Their Own Work*, edited by Andre Mercier and Maja Svilar (Bern: Peter Lang, 1983), pp. 209–26 (in SWAN IX). Another source for insightful material on Naess and A. J. Ayer (as well as six of their contemporaries) is a book created from debates by philosophers for Dutch National Television. See, especially, "The glass is on the table: An empiricist versus a total view," in *Reflexive Water: The Basic Concerns of Mankind*, edited by Fons Elders (London: Souvenir Press, 1974), pp. 11–68 (in SWAN VIII). Finally, additional perspective was offered by an article that discusses Norwegian philosophy from the end of the Second World War to just before 1980: Arne Naess and Jon Hellesnes, "Norway," in *Handbook of World Philosophy Since 1945*, edited by John Burr (Westport, CT: Greenwood Press, 1980), pp. 159–71.

On some of the fine points of this essay, I have benefited from extended conversations with my colleague and old friend George Sessions. I have also profited, over the years, from the significant literature that has been created to shed light on Arne's life and work. Many of the ideas and thoughts introduced in this essay—drawn from my own firsthand experiences with Arne—can also be found in these sources. In many cases, issues only touched on here are taken up in much more detail in those sources. Five key references for historical material on Naess and the evolution of his philosophical approach are identified below (two of which are videos). A wealth of additional material is available in the five festschrifts for Naess (see details in note 15 below). The

SERIES EDITOR'S INTRODUCTION

first of the festschrifts, *In Sceptical Wonder: Inquiries into the Philosophy of Arne Naess on the Occasion of His Seventieth Birthday*, edited by Ingemund Gullvåg and Jon Wetlesen (Oslo: Universitetsforlaget, 1982), contains the most thoroughgoing analyses and critiques of Naess's earlier philosophy that I am aware of, and many of the articles have insightful responses by Naess.

Books

Warwick Fox, *Toward a Transpersonal Ecology: Developing New Foundations for Environmentalism* (Boston and London: Shambhala, 1990). See, especially, chapter 4, "Arne Naess and the Meanings of Deep Ecology."

Ola A. Hegdal and Tore Strand Olsen (illustrator), *Jeg, Arne Naess: Et Tegnet Liv* (Arne Naess: A cartoon story of my life) (Oslo: Kagge Forlag, 2001). A unique and insightful look at Arne's life, based on an idea from Arne's wife, Kit-Fai.

David Rothenberg, *Is It Painful to Think? Conversations with Arne Naess* (Minneapolis: University of Minnesota Press, 1993).

Crossing the Stones: Arne Naess (Oslo: Norwegian Broadcasting Corporation, 1991), 47 minutes.

The Call of the Mountain: Arne Naess and the Deep Ecology Movement (Amsterdam: ReRun Produkties, Postbus 93021, 1090 BA, 1997), 50 minutes.

2. On Naess's effort to expand the concept of reason to incorporate emotions and feelings, see Arne Naess with Per Ingvar Haukeland, *Life's Philosophy: Reason and Feeling in a Deeper World*, translated by Roland Huntford, foreword by Bill McKibben, introduction by Harold Glasser (Athens and London: University of Georgia Press, 2002). As a testament to Naess's interest and influence in Norway, I note that in a country of about 4.5 million people, 150,000 copies of the Norwegian edition of *Life's Philosophy* have been sold. For a fine example of Naess's use of mythopoetics, see Arne Naess and Johann Brun (photographer), *Det Gode Lange Livs Far: Hallingskarvet sett fra Tvergastein* (The good, long life's father: Hallingskarvet from Tvergastein) (Oslo: N. W. Damm and Son, 1995). For other examples, see Naess's article on Tvergastein, his "Letter to the King of Nepal," and some of his writings on deep ecology in volume X of the *Selected Works*.
3. Most of these questions were drawn from Naess's discussion with Sir Alfred Ayer on the nature of philosophy and the problems it seeks to address (Naess and Ayer, "The glass is on the table," p. 14).
4. See Naess's "Ecosophy and gestalt ontology" in SWAN X.
5. Jakob von Uexküll, "A stroll through the world of animals and men: A picture book of invisible worlds," in *Instinctive Behavior*, edited by Claire H. Schiller (New York: International Universities Press, 1957), p. 14.

Singh, ed., *Environmental Ethics and the Power of Place: Festschrift to Arne Naess* (Varanasi, India: National Geographical Journal of India, 1994); Nina Witoszek and Andrew Brennan, eds., *Philosophical Dialogues: Arne Naess and the Progress of Ecophilosophy* (Oslo: Centre for Development and the Environment, 1997; Lanham, MD: Roman and Littlefield, 1998); Andrew Light and David Rothenberg, eds., *Arne Naess's Environmental Thought*, special edition of *Inquiry* 39 (June 1996).
16. Arne Naess, *Four Modern Philosophers: Carnap, Wittgenstein, Heidegger, Sartre*, translated by Alastair Hannay (Chicago: University of Chicago Press, 1968). In the 1970s, philosophy was still influenced by the events of the Second World War. Heidegger's flirtation with National Socialism and the Hitler regime, and his unusual way of expressing himself, made it difficult for him to be considered a great philosopher. Naess's book on four contemporary

SERIES EDITOR'S INTRODUCTION

philosophers was seen as unique because he interpreted in a scholarly and positive way both Heidegger and the fiercely anti-Heideggerian philosopher Rudolph Carnap, a logical empiricist. Carnap, who was forced to flee Nazi Germany, could not fathom how Naess, as an old friend, could present positive discussions of Heidegger and himself in the same book. The other two philosophers included in the book, Wittgenstein and Sartre, also held completely incompatible views of philosophy, but Naess accorded them equally high positive appreciation.

17. For example, works by Naess that are still in print, such as *Ecology, Community, and Lifestyle: Outline of an Ecosophy*, translated and edited by David Rothenberg (Cambridge: The University Press, 1989), and *Life's Philosophy* (2002; see note 2), were not included, for obvious reasons.
18. In "How my philosophy seemed to develop," p. 215, Naess mentions the particularly strong impression, the magnificent expansion of his own "life's frame of reference," made by H. G. Wells's early popularization of the history of life, *Outline of History* (New York: Macmillan, 1920).
19. For detailed discussions of Naess's assessment of logical empiricism, see Arne Naess, "How can the empirical movement be promoted today? A discussion of the empiricism of Otto Neurath and Rudolph Carnap," in *From an Empirical Point of View: The Empirical Turn in Logic*, edited by E. M. Barth, J. Vandormael, and F. Vandamme (Gent, Belgium: Communication and Cognition, 1992), pp. 107–55 (in SWAN VIII). (The original German version of Naess's article, "Wie Fördert Man Heute die Empirische Bewegung? Eine Auseinandersetzung mit dem Empirismus von Otto Neurath und Rudolph Carnap," was written during 1937–39.) For Naess's experiences attending the Schlick seminar, see Arne Naess, "Logical empiricism and the uniqueness of the Schlick seminar: A personal experience with consequences," in *Scientific Philosophy*, edited by Friedrich Stadler (Dordrecht: Kluwer Academic, 1993), pp. 11–25 (in SWAN VIII).
20. Naess, "How my philosophy seemed to develop," p. 222.
21. See Arne Naess, *Erkenntnis und Wissenschaftliches Verhalten* (Knowledge and scientific behavior or, more colloquially, Science as behavior), Inaugural Dissertation (Oslo: Norwegian Academy of Sciences, 1936).
22. John Dewey, "Experience, knowledge, and value: A rejoinder," in *The Philosophy of John Dewey*, edited by P. A. Schilpp (Chicago: Northwestern University Press, 1939), p. 597, as quoted in Wallace I. Matson, *A New History of Philosophy*, vol. 2 (San Diego: Harcourt Brace Jovanovich, 1987), p. 454.
23. Naess, "How my philosophy seemed to develop," p. 223. For more details, see Richard McKeon and Stein Rokkan, eds., *Democracy in a World of Tensions* (Chicago: University of Chicago Press, 1951). Naess, as the scientific leader of the project, was viewed as a UNESCO administrator; he was only credited as

SERIES EDITOR'S INTRODUCTION

being the author of the questionnaire itself and the summary paper, although he was intimately involved with the project at all levels.

24. Naess went on to perform a reconnaissance of Tirich Mir (25,263 feet) in the Hindu Kush in the summer of 1949. He then led the successful Norwegian first-ascent team in 1950. The expedition, which included botanical and geological assessments of the region, is chronicled by the team members in Naess et al., *Tirich Mir: The Norwegian Himalaya Expedition*, translated by Sölvi and Richard Bateson (London: Hodder and Stoughton, 1952). Naess successfully pursued a second, vastly more technical expedition to Tirich Mir in 1964. His "The south wall of Tirich Mir East," *Himalayan Journal* 26 (1965): 97–106, discusses this expedition and includes interesting commentary on expedition philosophy and climbing ethics. The article appears in SWAN X, along with other papers on Naess's relationship to mountains and views on mountaineering.
25. Arne Naess, "Reconnaissance, 1949," in *Tirich Mir*, p. 22.
26. 29. For a discussion of nonanthropocentrism as part of an ongoing historical tradition with ancient roots, see George Sessions, "Ecocentrism and the anthropocentric detour," in *Deep Ecology for the Twenty-First Century*, edited by George Sessions (Boston: Shambhala, 1995), pp. 156–83. For details on Douglas's effort to save the Everglades, see Marjory Stoneman Douglas, *The Everglades: River of Grass*, rev. ed. (Sarasota, FL: Pineapple Press, 1987).
30. See Arne Naess, "The shallow and the deep, long-range ecology movement: A summary," *Inquiry* 16 (1973): 95–100 (in SWAN X). For a more detailed, mature version of deep ecology, see Naess, "The deep ecology movement: Some philosophical aspects," *Philosophical Inquiry* 8 (1986): 10–31 (in SWAN X). For a concise overview of deep ecology that chronicles its key evolutionary changes and identifies the distinctions among the "deep ecol-

SERIES EDITOR'S INTRODUCTION

ogy approach to ecophilosophy," the "deep ecology movement," and Naess's "Ecosophy T" (a particular deep ecological total view), see Harold Glasser, "Deep ecology," in *International Encyclopedia of Social and Behavioral Sciences*, edited by Neil J. Smelser and Paul B. Bates (Oxford: Pergamon, 2001), pp. 4041–45. For a detailed discussion of deep ecology as an ecophilosophical approach with special attention to its policy implications and a discussion of deep ecology's relationship to Naess's earlier philosophical work, see Harold Glasser, "Naess's deep ecology approach and environmental policy," *Inquiry* 39 (1996): 157–87 (reprinted in Witoszek and Brennan's *Philosophical Dialogues*).

31. For anthologies on the deep ecology movement, which include articles by Naess and other deep ecology supporters, see George Sessions, ed., *Deep Ecology for the Twenty-First Century* (Boston: Shambhala, 1995), and Alan Drengson and Yuichi Inoue, eds., *The Deep Ecology Movement: An Introductory Anthology* (Berkeley, CA: North Atlantic Books, 1995).
32. Naess rarely responds directly and definitively to these criticisms—this is not his nature. Siri Naess, however, made an interesting effort to explore the potential of using Naess's Ecosophy T as an inspiration for a feminist normative system in her "Self-realization," in *In Sceptical Wonder*, pp. 270–81. She concluded that while Ecosophy T and her System F have much in common, Ecosophy T goes further by extending to all living beings its concern for activeness and creativity in relation to problems, egalitarianism, and support of the suppressed and exploited.

Author's Introduction to the Series

At ninety-two it is a great honor to be still alive and to witness the publication of my selected works in English. Few philosophers have their work published in a series, fewer still receive this honor before they die. When I was originally approached with the idea of publishing my complete works, I was overwhelmed and overjoyed, but added that not all my books and articles were important enough to merit such an honor. Selected works? Yes, and I am extremely grateful for this initiative and the final result, which presents a representative selection of my work from the earliest to the most recent. [*The Selected Works of Arne Naess* are hereafter referred to as SWAN.]

My interest in philosophy began with Spinoza's *Ethics*, which as a seventeen-year-old I was fortunate to read in Latin. I appreciated Spinoza's grand vision and trusted him implicitly as a person. I accepted that human beings could, and should, have a general outlook with the grandeur of Spinoza's, but I recognized that our individual views on this grand scale will not be identical. Through the years I have realized that there is a splendid variety of interpretations of Spinoza (SWAN VI and IX). His texts are exceptionally rich. As the years have gone on, I have focused on how he leads us to realize we can increase our freedom and sense of connection with the world through strengthening and intensifying our *positive* emotions. For example, loving and caring for our place and others leads to an expansive sense of being part of a much larger world. Emphasizing hatred and anger, on the other hand, makes us feel smaller and isolated from the world. Spinoza, as I interpret him, would express this by saying that "We are as large as our love." Increasing our freedom as human beings leads us toward life in communities colored by friendship, sharing joy and sorrow.

Before I left gymnasium [the end of secondary education] the headmaster asked me, "What do you intend to be?" My immediate answer was "A philosopher." In fact, I had already conceived of myself as one. I viewed the

AUTHOR'S INTRODUCTION TO THE SERIES

writings of many contemporary philosophers that I was familiar with, however, as vague and airy and certainly not as inspiring as Spinoza.

My doctoral thesis in philosophy of science was an effort to remind us that in science the content of a theory is not independent of research behavior—the activities of observing, confirming, disconfirming, and so on, and that these are set within a deep context of place, history, and culture. Later, as a postdoctoral researcher at the University of California at Berkeley, I studied the behavior of experimental psychologists doing animal research.

In 1934 and 1935 I studied in Vienna and while there became a member of the famous Schlick seminar, the main discussion group of the Vienna Circle. Their quest for clarity and cordial cooperation in pursuit of knowledge led me to appreciate that “What do I mean?” is an open question. I concluded that we never intend to express anything extremely definite, even in mathematics or symbolic logic. I saw the importance of using empirical methods to find out how we actually use certain expressions and sentences. I developed and applied a wide variety of such methods, which became part of the core for the empirical semantics that runs through my work. I continued to do this type of research into the 1990s, my last project being one in which I questioned experts and policy makers about their ideas of values intrinsic to the natural world (in SWAN X).

In one of my earlier studies, I reviewed about 700 articles from philosophers concerning their use of the word *truth*. For the most part, I found these unconvincing and soon started on empirical studies of the use of *truth* among ordinary nonprofessional people and schoolchildren (in SWAN VIII). Many philosophers seemed to assume that ordinary people hold very naive views about these deep matters. I found through research that, on the contrary, the views articulated by these “ordinary” people were every bit as sophisticated as those held by professional philosophers. This reinforced my conviction that, generally, we greatly underestimate ourselves. Much academic philosophy was narrowly focused and abstract. Philosophers who elicited interest in wide-ranging issues of practical and global importance, such as nonviolence and social justice, have in my lifetime said things that were considered creative, but often too far out. In spite of consistent proclamations that science neither would nor could take over all the problems discussed by philosophers, I tried to argue in ways that reminded readers of science done as open inquiry, and I tried to emphasize that it is occasionally

AUTHOR'S INTRODUCTION TO THE SERIES

necessary to perform empirical research to illuminate or support a philosophical viewpoint.

My empirical and historical research led me to realize that there are no certainties and that there is a great diversity in our spontaneous experience as well as endless ways to describe and appreciate the complexities and values of the world. Thus, I realized that I am one of those lifetime seekers that the ancient Greeks called a *zetetic* (see SWAN II and VIII). From my research on scepticism and the foundations of science and logic, it became clear to me that pluralism (every event has many descriptions and possible outcomes), possibilism (anything can happen), and a healthy scepticism (always seeking the truth but never claiming it) make up the most consistent approach to respecting the perspectives and experiences of others, human and nonhuman.

From my empirical studies of semantics, and from my knowledge of several languages, I came to appreciate the complexity of communication. Being committed to Gandhian nonviolent communication, I saw the importance of avoiding dogmatism and fanaticism. One of the most important discoveries coming from this research, leading to the publication of my major book, *Interpretation and Preciseness* (SWAN I), was the insight that we cannot avoid values in any field of endeavor or research. There are no value-free inquiries or theories. Even if we refuse to express our values, this is itself an expression and choice of values. We must, therefore, be clear about our value choices and try to make them explicit. The choices we make, as Spinoza pointed out, shape the quality of our lives, and values emphasizing positive emotions or feelings are expansive and lead to our growth. We must become ever more aware of our choices and the values involved. Even pure logic assumes certain norms. Empirical research can shed light on these matters. My colleagues in philosophy often found my empirical work perplexing. I, in turn, grew to underrate the necessity of visiting great centers of philosophy, as I preferred to be close to or in the mountains.

When I visited the United States, it was mostly to climb in the mountains or walk and camp in the desert. On one fortunate visit, I dropped in at the graduate students' discussion room at Harvard. Speaking with students who were writing their doctoral theses in philosophy, I understood that my knowledge of contemporary philosophy, and of recent important contributions in its various fields, was narrowly limited to special themes of lively personal interest. Even in later years, the tendency to take personal inclina-

AUTHOR'S INTRODUCTION TO THE SERIES

tion very seriously colored my contribution to the philosophical literature. As can be seen, though, from the titles in these *Selected Works*, my strongly felt interests span a rich variety of fields, philosophical traditions, and movements.

Since childhood I have experienced an intense joy in being together with animals and plants and in contemplating the immense evolutionary development of life on earth over millions of years. From an early age I also developed an intense love for mountains and for being in them. Much of my creative philosophical work was done at Tvergastein, my mountain hut in Norway (see SWAN X). My devotion to outdoor life is in the Norwegian tradition called *friluftsliv* (literally, free-air-life). In many respects, I approached philosophical and cross-cultural studies as if I were a field ecologist or naturalist. It was against this background that my work from the 1960s onward focused with close attention on cultural diversity, biodiversity, sustainability, and the deep ecology movement.

My work since the Second World War has been increasingly within movements such as those furthering social justice, peace, and ecological responsibility. During the war, I engaged in anti-Nazi activism, and from that time also in promilitant Gandhianism, a nonviolence that is not pacifist in the usual sense but insists that if it is a bloody fight for justice against injustice, we seek "the center of the conflict" and, if necessary, cooperate with people who use arms. During the Cold War, I participated in the "third side," against both communism and extreme anticommunism, for example, as the scientific leader of a UNESCO project bringing Marxist and anti-Marxist politicians and political science researchers together in an unbiased discussion of the essence of democracy and freedom. Some of the relevant publications are included in SWAN IX.

The broad spectrum of books and articles included in the *Selected Works* represents, in many ways, a chronicle of my passions and influences. The *Selected Works* record, albeit in an inevitably fragmentary way, one possible expression of these. My dream and hope is that some readers will be inspired by their sheer variety, and that young philosophers will be encouraged to let strong personal motivations steer their studies.

Working habits vary. Some people write an article and go on to the next without looking back on the old one; others come back from time to time, radically revising and changing the old one. The latter is my way of working. Lecturing in many places about these subjects, I have found it

AUTHOR'S INTRODUCTION TO THE SERIES

natural to revise the old manuscripts until sometimes very little is left of the original. Therefore, I have always viewed my writing as preliminary; a year, five years, ten years after publication of the first editions I have itched to revise, *thoroughly* revise them. When my first book was printed in 1936, I went to watch the hulking presses printing out one page at a time. I was terrified, thinking of mistakes or some awkward sentences being duplicated again and again.

When I was offered the opportunity to have a selected-works series published, I immediately thought I would like to review all my work and ask how, from today's perspective, I might answer the difficult questions I had earlier attempted to probe. Such a task would have been a particularly difficult proposition, because although many of my books and articles contain new ideas, the ideas are often not developed as well as I might have hoped. But alas, I am saved—at my age there is not time for me to accomplish such a comprehensive reevaluation of my work; I do not even have the capacity to do it now in any case.

Who could contemplate undertaking a publishing project of such ambitious proportions? Douglas Tompkins, mountaineer, entrepreneur, protector of wilderness in Chile and Argentina, and creator of the Foundation for Deep Ecology, is such a person. "Miracle Doug," as I call him, likes the idea that the deep ecology slogans and the deep ecology approach were introduced by a philosopher. I am grateful to him for his firm conviction, inspiration, and great generosity. My gratitude, however, extends well beyond my thanks to Doug, to others who have supported and championed this project.

Quincey Imhoff, when executive director of the Foundation for Deep Ecology, supported SWAN with generous grants and other contributions. SWAN has also benefited from faithful assistance and cooperation in the preparation and editing of the manuscripts. The late Professor Ingemund Gullvåg prepared the initial translation of *Which World Is the Real One?* (SWAN III). Professor Alastair Hannay translated the first edition of *Communication and Argument* (SWAN VII) and offered invaluable suggestions for improving the readability of the first editions of *Scepticism* (SWAN II), *The Pluralist and Possibilist Aspect of the Scientific Enterprise* (SWAN IV), and *Gandhi and Group Conflict* (SWAN V).

Most of all, however, I am grateful to Harold Glasser, the series editor, and his assistant, Kim Zetter, who oversaw all aspects of the project from design to production. Glasser's unique combination of intellectual tenacity,

AUTHOR'S INTRODUCTION TO THE SERIES

attention to detail, mastery of my work, and cooperative spirit made him a natural to take on the monumental task of selecting and editing my works. Glasser not only labored to improve the English and clarity of each manuscript, but his keen ability to ferret out countless technical and pedagogical errors has resulted in substantial new editions of volumes II–VII that are both far more comprehensible and accessible than the originals. I thank him for his valiant work on this project, both during his stay in Norway as a visiting Fulbright professor, where we collaborated on a strategy for revising the previously existing material, and in the subsequent years it has taken to complete the project.

From the beginning of the SWAN Project in 1994, Alan Drengson has encouraged and helped to move this work forward in numerous ways. Especially in the last crucial stages of completing volumes I, VIII, IX, and X, his help and editorial oversight have been invaluable. Thanks for his devotion, good humor, and positive enthusiasm. Thanks to both Drengson and Tim Quick for their extensive bibliographic research. Thanks to Bill Devall for his support and encouragement and especially his help on the completion of volume X, *Deep Ecology of Wisdom*. Thanks to Anne Collins for her outstanding work as the copyeditor of the SWAN volumes. Thanks to George Sessions for his support and encouragement.

Last, but certainly not least, immeasurable thanks go to my wife, Kit-Fai Naess, who has worked beside me throughout the years to provide invaluable assistance, encouragement, and inspiration.

Author's Preface to This Edition

An urgent issue today is whether economic globalization with a strong world market will make deep cultural differences impossible. As of now, there are still cultures that significantly differ from one another, with diverse views about nature and the world. At least to some degree, these differences can be articulated. We then get systems that are comparable in a rough and superficial way. Comparisons presuppose some common fundamental but very general ideas and procedures.

There are many worldviews, but is there only one *real* world? This question is taken up in this SWAN III volume. Twenty-five years of gradually less creative thinking have not changed my opinion in these matters. However, recent developments in philosophy have accentuated the problems in unpredictable ways. There is doubt among some anthropologists about the very concept of culture and especially about deep differences. Furthermore, doubt exists about concepts of foundations, which also touches science. "Science without foundation!" (Feyerabend). Is this merely an overreaction to extreme dogmatism—for example, the arrogant announcement that one has found the only conceivable set of ultimate premises that are absolutely valid? Such arrogance is rare, and markedly different from the single exposition of one's ultimate premises with an implicit claim that they are valid. I expect that existential philosophy of life and cosmos will flourish in the twenty-first century. No worldview will survive as THE real one.

Karl Jaspers's (1919) book *The Psychology of World Views* surveys and classifies personal worldviews. It is unique for its comprehensive and philosophical sophistication. It is sad how little influence it has had on recent philosophy-of-life reflections. Classification along his Dimension No. 2 has three subclasses. In rough English translations of the German text,

AUTHOR'S PREFACE TO THIS EDITION

they are: nature-mechanical worldviews, nature-historical worldviews, and nature-mythical worldviews.

It is astounding how much the richness of these worldviews has been underestimated and also how resilient they are to criticism. For example, materialistic systems are regularly said to be unable in principle to include theology and a supreme God. Yet, such systems were propagated in ancient Greece. For the atomists, God consisted of very smooth atoms communicating with us by means of extremely delicate waves emanating from those atoms. The crude waves of human communication, as well as the waves from sheer noise, usually make the waves from God inaudible. Therefore, meditation and listening in deep silence are recommended by proponents of these worldviews.

In short, and schematically, the natural, rich diversity of worldviews goes unrecognized because of mutual distrust: If a philosopher A offers a set of basic premises P_A , a second philosopher B says that from P_A something follows that everybody considers unacceptable. However, B would say that this something does *not* follow from P_B , and would add that from P_B such and such follows, which is clearly acceptable. There is a reluctance to give other creative philosophers “plenty of rope,” an expression I borrow from William James but one that is also well known to mountaineers. There is a tendency to choose interpretations of the texts of others that place their philosophy in a bad light, rather than ones favoring friendly cooperation in the unending pursuit of truth.

This book (SWAN III) makes use of my empirical semantics techniques, which offer sets of basic premises expressed in vague, ambiguous sentences as points of departure, formulations that are essential at the initial stages of an inquiry. The aim is to open the mind for encounters—never complete within a world of irreducibly different worldviews. In the second edition of this book, I invited readers to combine philosophical inquiry with cultural anthropology. The aim is to help prevent the reduction of the rich cultural and subcultural diversity that is essential for the further development of humanity. The long-term radical development of *Homo sapiens* may be cultural rather than biological. This requires protection of cultural mutations against the domination of a single family of similar industrial or green societies.

Strong economic forces are pushing for a world market that allows the free flow of capital, goods, services, and labor. It is difficult to see how

AUTHOR'S PREFACE TO THIS EDITION

deeply different cultures, some of which may be economically weak and vulnerable, can survive this onslaught. Provocative subcultures will survive, but in subcultures the continuity through generations is endangered. There is, for example, the need for proper school systems adapted to specific subcultures.

The philosophical systems of Aquinas, Spinoza, and Hegel are, in limited ways, meant to cover everything. In Indian and Chinese philosophical traditions, analogous systems have been created. In the [twentieth] century, linguistic philosophy has prevailed, especially in English-speaking countries, but grand systematizations may well see the light again. The two main arguments against the future value of *total views* are weak. The first, that they are too dogmatic, seems to be caused by the belief that the more general the view, the more likely it is that it will not be changed. However, Spinoza changed his views all through his life, and the same holds, as far as we can tell, for others. The second argument says that critical thinkers, such as Kant, have definitively shown the impossibility of reaching the goal of comprehensive metaphysical systems. However, such "proofs" are only hypothetical and have highly controversial premises.

In this book I accept the cognitive and practical value of systems but hold that the more like a total view they get, the less comparable they are, and the smaller are the possibilities for falsifying or undermining their fundamental tenets through argumentation. The change from acceptance to rejection must contain cognitive steps. In the terminology of some post-modernists, systems need "deconstruction." Others point out that all deconstructions, and their premises, may be deconstructed. The latter seems obvious to me. Worldviews of the most comprehensive kind have a great future as important cultural assets.

How can we live without taking seriously our feeling of what it means and entails to be a human being? How can we ignore the seemingly deep differences between people both in how they actually rank values and in how they act? We may ignore our more or less spontaneous, vast generalizations about life, and deeply different life conditions in different countries, or even in our own environment. We may consciously repress our vast generalizations, talking about a better life here rather than there, about the worst kind of life and the best. If asked, we may even deny that we have any

AUTHOR'S PREFACE TO THIS EDITION

view about life and the world. Some may laugh at the arrogance of people who profess a life- and worldview (*Lebens-und Weltanschauung*). These almost untranslatable terms were created in a country that has excelled in visionary generalizations, but where now the professional philosophers mostly reject the value and even the meaning of contributing to systematizations of life- and worldviews as all-embracing views.

I find untenable the prevalent rejection of life- and worldviews on the scale of Aquinas and Spinoza in the West, and of some great Chinese philosophers in the East. Since the 1960s I have consistently talked and written about a renaissance of great systems, that is, verbalizations of how one feels and thinks about existence, life, and the world in general. After all, some children by the age of four ask questions of a sublime and general character. In my opinion, no one has shown, through logic, philosophy of language, or any other kinds of arguments, that such grand systematic efforts are meaningless and fruitless. Should we leave these great tasks to the four-year-olds? We should all be able to have such fun!

Curiously enough, some critics see it as an imperfection that there is no consensus in questions of *Lebens-und Weltanschauung*. As long as there are deeply different cultures, and deeply different subcultures, we have reason to hope that the general outlook on life and the world will offer a great richness of fruitful differences, on par with the vast potentialities of human and natural creativity. Our spontaneous experiences and individual and cultural differences are a source of diversity that reveals the complex and deep richness of the *real* world.

Arne Naess

2004

Introduction

There is today a strange belief that science will slowly but surely solve all questions that have the possibility of a solution. With a scientific world-view as our framework, we will gradually elucidate human ends and activity, at least in all theoretically essential and practically important features. Because it is fruitless to try to anticipate the results of science, it is often argued — although unjustifiably — that it would be similarly fruitless to try to create more comprehensive syntheses than those permitted by scientific research. Such efforts may have their human uses, but they are not likely to be of any use in furthering science.

It is often said that extrapolation is unscientific and reveals a want of mental discipline. A wait-and-see attitude is more proper. Future generations will acquire a general view that we are not yet able to discern. Until then, the scientific attitude, the only intellectually honest one, dictates silence.

What happens, however, if our assumption that science will be able to generate a comprehensive world picture is an illusion (based on false conceptions about science)? What if we will have waited in vain? What if it is a delusion to believe that such a picture can emerge as a conclusion after innumerable single investigations?

Doubt with regard to the assumption that the more we perform scientific research the closer we get to a total view of the world, is not new. This doubt, however, is supported in very different ways. One standpoint argues that what purports to be a scientific world picture is an extrapolation in, scientifically speaking, unknown or insufficiently clarified dimensions. This criticism is based on a premise regarding the infinite multiplicity of types of phenomena in the world. If growing scientific knowledge is compared to the enlarged illuminated area that results from increasing the luminosity of our lamps, then the premise suggests that an ever larger area of

INTRODUCTION

darkness is also exposed. As more scientific problems are “solved,” so grows our capacity to formulate new unsolved problems.

A second standpoint stresses that science, in its basic features, is predetermined by its methods, axioms, postulates, and rules. These basic features cannot be the product of scientific research; they are presuppositions, not results, of research. The corollary is that the results of science cannot be integrated into any specific scientific world picture, but they may, perhaps, be integrated into philosophical world pictures, insofar as scientific presuppositions are subjects for philosophical research.

We are not on “the long road of approximation” (Kierkegaard) but in a historical process that causes the fragments to vary in character, to be perceived in new ways within a totality that itself varies and is not at all scientifically justified or justifiable in itself. Changes in methods, axioms, postulates, and rules are frequently, or perhaps always, at least in part motivated by results of research, but they cannot be said to be scientifically *justified*. Furthermore, the basis for making such modifications seldom seems to be self-evident, even to active researchers. Even if this were the case, we would still have the problem of *explaining* changes that were viewed as self-evident by individual scientists.

Let us return to the question of the possibility of a synthesis that is either a combination of the scientific and philosophical or is “purely” philosophical. In relation to this problem, as with others, one must distinguish between scepticism (Zeteticism, Pyrrhonism) and negativism (“Academic scepticism” in Greek terminology). The negativist denies human beings the *possibility* of working out all-embracing syntheses that can stand up to critical scrutiny. The sceptic—more precisely the Pyrrhonic zetetic—*seeks* (*zeteo*) to solve the questions that must be solved if the task is not to be declared impossible. The seeker thinks that what has been achieved so far does not measure up as an expression of plain, verified truth. There is no compelling reason to accept some relevant conclusions as more true or probable than others. A combination of two attitudes is suggested then: a seeking, sceptical attitude toward all total views, and a positive attitude toward wonder, not only as a point of departure, but also as the endpoint of philosophizing. (Beyond what I do understand, there seems, fortunately, to be much that I do not understand and shall never understand of philosophy and human cultures.)

INTRODUCTION

What follows here is motivated by this kind of seeking, sceptical attitude toward what already exists in the way of syntheses. The investigations in this book are sustained by delight in the multiplicity of ideas for syntheses that are already available to us in the twentieth century. It is a pleasure to contemplate and, to a very modest degree, to reexperience generously worked out, widely differing philosophies, basic attitudes, and views of the world and man. This is the pleasure of a wanderer, or rather a vagabond. The vagabond, in this sense, does not constantly seek to compile and integrate experiences.

Following these rough guidelines, we will treat my preceding sentence, which suggested that the results of science cannot be integrated into any single world picture, as a working hypothesis, not as a thesis I claim to be true. This hypothesis is based on historical and other studies that, besides being fragmentary, rest on methods and postulates that are not self-evident and fixed but admit to variations. It would be dishonest, however, to pretend that while writing this “thesis” and elaborating its consequences I do not have *trust* in it or an implicit confidence in its truth. The comfort that the dogmatist finds in conviction and hope, the sceptic finds in trust and wonder.

There is a belief that it is possible to create compendia of the history of philosophy that would clarify the exact interrelationships between individual philosophies with regard to their specific contents. At this point I see no possibility for such a survey and feel content to stand before something that unfathomable, something that no one can classify adequately.

Faced with someone who sees a want of engagement in scepticism, I would have to draw his attention to the fact that adopting a sceptical attitude makes it easier to gain insight into more than one view of life. Engagement without insight into the unfamiliar occurs on a false basis. If one is all the time certain in one’s heart where, or in what direction, Truth is to be found, insight into the unfamiliar becomes impossible. If one takes a certain presupposition as one’s point of departure, one cannot gain an intimate understanding of something that has an opposite presupposition. To do so, one must uncover one’s own presupposition, be willing to abandon it, identify oneself with the opposite presupposition, and see “everything” from this other point of view while at the same time maintaining a connection with the old presupposition. This involves at least a temporary relativization or suspension of

INTRODUCTION

both presuppositions. As long as one is convinced that one of them is more probable or true than the other, such a relativization is not possible. One cannot, as in the specific sciences, say, "If one presupposition is accepted, then so and so follows; if the other one is accepted, however, then such and such follows." Philosophies are too profound for such calculations; one has no immutable reference point from which to launch the if-then sentence.

Some may say that this delight in the multiplicity of alternatives must have some limits. How can one, for example, take pleasure in fascism, Nazism, Stalinism, or other extreme views of the world and man? The problem, however, is only ostensible: At the beginning of the twentieth century, attempts were indeed made to lay a philosophical foundation for fascism, but no great philosophical movement addressed such issues. No outline of a fascist philosophical system exists that is worth mentioning or that can be subjected to systematic analysis.

Scepticism, as a method of seeking, presupposes that one at least has ideas of what one is seeking. If one has the pretensions of a researcher, this implies that at the very least the ideas are sufficiently conceptualized to provide goal-standards (at least hypothetical ones) for what one seeks. A kind of standard of truth and genuineness must be retained, even if more precise formulations are held in suspense. In this sense, scepticism has at least one limit, but it is not a fixed limit. It is itself subject to wonder and search when we succeed in bringing it to awareness.

It is commonly believed that system construction must be accompanied by a blind faith in the system's truth and a strong belief in the falsity of other systems. The system creators whose ways of working are known to us, however, were constantly revising their standpoints, and one can trace their movement through many outlines and attempts. What they were sure of was a kind of intuitive, inarticulatable insight that their systems sought to express adequately. In relation to the articulated parts, these philosophers were regularly nondogmatic. Nevertheless, unfortunately, the locution *system* was and remains associated with *dogmatism*.

In what follows we shall distinguish sharply between a proposition's *degree of generality* and the *claim of certainty* with which it is asserted. One can pretend that a very specific statement (for example, about the blue anemone) is certain, and that an immensely general statement is highly uncertain (for example, about all the plants in the world). It is unreasonable to

attribute far-reaching pretensions of certainty to a philosopher simply by virtue of his expressing himself in very general terms and claiming, for example, that some of his statements are a priori. The a priori character does not relate to pretensions of certainty, but to relevant ways of verification. The great apriorist Nicolai Hartmann is particularly clear on this point.

Nevertheless, with regard to the intellectual legitimation of attempts to formulate a system, it is decisively important to consider one's standpoint on the question of whether implicit assumptions incorporating system character can be avoided at all. Perhaps the antisystematist is merely a person who does not want to, or dare to, bring his own attitudes to awareness and subject them to systematic articulation. Such an attitude cannot count on sympathy in philosophical debate.

Philosophers with deep respect or veneration for the sciences have noted how many systematizers have trudged carelessly or uncritically when considering a scientific topic (for example, Hegel in relation to Newton). These philosophers have also noted that some systematizers, out of excessive respect, exalted scientific hypotheses to all-embracing theories (for example, Spencer on Darwin). Owing to such unfortunate phenomena, there is a lamentable tendency to reject the study of systems.

The word *synthesis* is less central philosophically than *system*, but it generates more associations in the direction of this book's thrust. According to these associations, a synthesis does not have to mean that the various constituents are tightly knit and that the whole is closed. It is enough for the parts to be seen together; it is adequate that these parts or aspects of man, the universe, values and facts, or poetry and science are instructively related to each other. Inadequate synthesis would then be a matter of deficiencies if one asked the critical questions "How does this philosopher make room for . . . ?" "What is the standpoint of this philosopher to . . . ?"

One weakness of the term *synthesis* is that it deprives us of thinking of systems as originating in ways other than by bringing together things that were not united before. If one way of viewing the world and oneself is central for the system maker, the system may be said to be created by analysis of the manifestations of this way within various areas of cognition-logic, methodology, epistemology, psychology, and so on. Alternatively, the system may be created through differentiation of an unstructured whole, just as a newborn gradually learns to respond to different phenomena.

INTRODUCTION

Let us, however, return to the question of whether we can acquire an adequate overview of systems. It may be the ambitious dream of a historian of ideas to show how each philosopher's thoughts can be explained in terms of influences from other philosophers, from the milieu, from his time, and from everything else except the philosopher himself. But is a philosopher a kind of empty barrel?

Great philosophies are created by highly distinct personalities, and even the most abstract parts of their philosophical systems are expressions of living human beings and ways of seeing, feeling, and thinking. It would be a miracle if we could reexperience the world through the eyes of Plato and then Aristotle, Thomas Aquinas, Descartes, and Spinoza. As one concentrates on a particular philosopher, it simply becomes more difficult to bring out the differences between his view and others from any standpoint other than his own. Indeed, the difference seems to be that the others are wrong or do not see the whole truth. Plato did not see the world as Democritus saw it. Aristotle seemed unable to familiarize himself with the ways the pre-Socratics saw it. How could *we* possibly acquire an overview and see through the whole series? Do we have appreciably better qualifications, greater intellectual power, and more empathy than Plato and Aristotle?

We cannot expect to understand a system's sentences—even the most seemingly colorless and neutral ones—exactly as their author did. We can perhaps, to some extent, approach an authentic understanding and thereby look into worlds with essentially different structure, emotive atmosphere, and intellectual appeal from the one we habitually frequent—if, indeed, we frequent any definite world at all.

The road to an approximately authentic understanding presupposes, I think, that one turns away, *at least temporarily*, from all so-called surveys of philosophy and its history. By reading such works, one obtains a technique of acquisition and orientation that is limited to the surfaces of those systems. In learning to gloss over these, however, one remains cut off from a nuanced and deep understanding.

In Scandinavia, especially in Denmark and Norway, for more than half a century students learned a kind of survey of the history of philosophy that manifested itself, for example, in the selection of philosophers considered worth mentioning, in choosing how many “pages” were devoted to each philosopher, and in characterizing the relevant “-ism” terms. These terms are regularly taken as an indication of which characteristics are espe-

cially important among the innumerable possible ones. If it were possible to communicate in a few words and in a short time the most essential aspects of a philosophy, then even Spinoza would be blamed for having used several hundred pages to communicate what was most essential for him. In surveys of philosophy one might be able to include the most important *words* and *sentences*, but not the most important *concepts* and *views*.

In my own history of philosophy (Naess 1980), I have not wandered far from the beaten path except for a wide-reaching elimination of the vulgarizing “-isms.” The main reason for my conservatism is that I have not been able to find convincing arguments for choosing between the range of new alternatives.

In addition, it may seem difficult to oppose and renounce the grand overview because so many authors seem to master our cultural history so sovereignly. They are able to place and classify philosophers and schools of thought so that everything seems surprisingly intelligible. What is needed, however, is more abhorrence and less admiration for such things. Only when one can, without embarrassment, declare to himself and others that he has no adequate overview whatsoever, and that with few exceptions he is perplexed about what the various philosophies even involve, is there room for pleasure in the quite small approaches to deeper understanding. Grand surveys of philosophy and the history of ideas may then be tolerated simply as learned authors’ reports of whims and thoughts that they have gleaned while reading old texts and contemplating old works of art.

Indeed, lecture series or compendia of philosophy covering long periods of time are banished in some seats of learning. In others, they still have an important place. A researcher who accepts a position as a philosophy teacher at such an institution must face up to the fact that he may be required to lecture, within a limited number of hours, on a series of gigantic philosophical systems created by thinkers whose intelligence and perspicacity he is at the same time expected to bow before in awe. Furthermore, he must extract the “essentials” of the specifically philosophical contributions of the philosophies, indicate how one philosophy influences the other, and, more generally, how each fits—or does not fit—into all-encompassing, widely differing cultural epochs. For some of us who have participated in this, there is not only something unworthy but also something fascinating in such an arrangement. The manufacturing of philosophy accounts in pill form has perhaps sprung from excellent motives—the cultivation of

INTRODUCTION

our “cultural heritage,” respect and veneration for profundity and genius in generations other than our own, and even recognition that the road to truth cannot be established straightaway without inspecting different roads—but cruelty and noble motives often go together.

A survey is no hindrance if it is phrased so as to make the reader understand that he is moving on the surface and will become familiar with key words and important formulations, but not much more. Unfortunately, such representations are rare, and few readers appreciate such limitations. Most readers want a comprehensive survey of what is most essential that covers the most heterogeneous philosophies.

What, then, is so reprehensible about such a comprehensive “overview”? It is the fact that it reduces something immeasurable to something perspicuous, easy to grasp, and uniform. It favors pigeonholing, ordering, and control at the expense of imagination and empathy. What is unreasonable about the idea of an adequate overview covering all of philosophy is the implicit conception that heterogeneous, deep, and consequential thoughts can be demarcated and grasped in one and the same mind or in one and the same conceptual framework and that they can then be presented to any moderately gifted individual who makes a slight effort to grasp them. It is simply assumed that individuals can “approach” a deeper and more exact understanding of all philosophies without generating discontinuities, crises, blind leaps, or new difficulties. Kant, however, had great difficulty understanding Hume, and Berkeley found Spinoza rather unintelligible. Kant and Berkeley required, as do many of us today, a certain depth of understanding; they were not satisfied with a mere surface-level grasp. Therefore, they failed to create grand, total overviews.

Travel agencies, for example, often give advice about how to see Europe in one, two, or three weeks. One can actually see all the most famous places and works of art; nevertheless, we would say that this is a rather superficial introduction. It is hardly different in the worlds of thought. Philosophies are not suitable for sightseeing in the course of a few weeks. If one attempts to introduce someone into these worlds in this manner, one commits an injustice to the thinkers as well as to those who seek an understanding of them.

A philosophical system covers “everything,” and therefore the ego itself and the relationship between the individual and tradition. To understand two different systems, then, one must be able to perceive oneself and

INTRODUCTION

the world in two different ways. This requires significant training and much time and effort. It involves creating discontinuities in one's own person; one becomes another, and then yet another, and then returns "to oneself." It is doubtful that one returns to "oneself" as one was originally. This alone makes the possibility of obtaining an overview of *both* systems dubious. Who is the person who has the overview?

After these strong words against the pretensions of adequately surveying philosophical systems, some admissions are in order, particularly pedagogical ones. In the first encounter with the history of philosophy, it may be useful to sample widely differing philosophical terminologies in order to become stimulated to find something from which one can profit personally. Such superficial encounters can often be sufficient to give one an inkling of what kind of philosophy or which philosophers one will be able to study with great profit. Attempts to suggest main thoughts and tendencies in different philosophies in quite simple words and without any pretension of adequacy are an important pedagogical task. Understanding comes gradually, and at every stage there are specific ways of formulating one and the same topic.

I

Descriptions of Maximally Comprehensive Perspectives

Context and Overview: Some Questions

Plato claims that only a life subjected to examination and evaluation is worthy of human beings. Hence, he presupposes that we can examine, inspect, and evaluate life; that we can, as parts, grasp the whole. Starting with our childhood, we can successively enlarge our object of investigation until it covers our whole (unfinished) life as it unfolds in a world that must, in the main, be assumed to be known.

The philosopher sees things in connection with each other and seeks to articulate what he sees in the form of statements that something is thus and not otherwise. Let us, for a moment, dwell on the words and concepts in “The philosopher sees things in connection.” What does this sentence mean? Do the things comprise *everything* minus the philosopher and viewer? How comprehensive is “everything,” and what does the subtraction involve? When we begin to analyze such a sentence, problems emerge that are bad omens for the possibility of realizing comprehensive systems as well as the potential for renouncing systematic theories. The word *things* may make us focus attention on “things” in a narrow sense; for example, rigid bodies, but what we need is an exceedingly broad concept, something that also comprises awareness of things, something that comprises both π and justice, the philosopher himself and his insights and illusions.

This brings us to the next point, that the philosopher does not see much when he sees the way two things are related. Here we need the concept ‘see’, which philosophers have sought in vain to agree on. The context in which everything is seen must comprise the absence of many kinds of close connections; otherwise, one excludes the radical pluralist, as William James sometimes characterized himself, from the circle of philosophers.

One may have insight into the absence of something, and in something being an illusion. (What *is* it then and where in “the world” does it belong?)

A brief consideration of these words and concepts is likely to remind us of the superficial level on which our investigation must, in certain senses, remain. This is inevitable if we are to avoid immediate bias: as soon as we start precization and articulation of a conceptual framework, it is difficult to stop before we find ourselves standing inside the frame of presuppositions of a quite specific kind of philosophy. Therefore, we have precluded even a superficial consideration of other philosophies. It is perhaps similar to the view of a landscape. If we lose ourselves in beholding one tarn, not only do we lose contact with the other tarns, but also the original object — “small dark tarn in light landscape” — disappears. We move even farther away from the original object if we step down into the very tarn that we were viewing from a distance!

“World picture” is a metaphor that suggests all things may be seen in connection. World pictures are mental images of the whole world and, as such, there may be many of them and they may be compared at leisure. It sounds suspiciously simple. Can we really acquire an album of world pictures?

In Karl Jaspers’s *Psychologie der Weltanschauungen* (Psychology of world-views, 1919), he says that by a “world picture” he means “that which is objectual for man.” Jaspers’s term *objectual* (*gegenständlich*) is useful inasmuch as it alludes to an object concept that is much wider than the ordinary thing concept. However, it emerges from his own characterization of world pictures that this descriptive definition is inadequate. What Jaspers writes about are the kinds of syntheses that human beings form of the objectual (for example, a mythological cosmology and anthropology). Jaspers’s formulation would cover his actual use of the expression more adequately if he defined “world picture” as “picture of what is objectual for man,” or if he defined “the world picture of a human being” as “the picture of what is objectual for this human being.” The relativity — or rather the relationality — emerges clearly in the last formulation. The following problems arise: How can a human being perceive that others also have world pictures and that these may differ from his own? Furthermore, if a human being can perceive the world pictures of others, do these then become parts of his own? (If the world pictures of others are something objectual for me, they must, according to Jaspers’s modified definition, be parts of my world picture.)

In spite of his, in a certain respect, very wide concept of world pictures, Jaspers does not permit worldviews to be determined by the world pictures alone. He characterizes worldview as a combination or synthesis of world picture, attitude, and spiritual type (*Geistestypus*).¹ Thus, there is something outside a conception that nevertheless determines or characterizes it. There is, at least in part, a psychological element, a specifiable attitude, that produces the particular view of the objectual. Even if the presence of this element raises purely practical problems for the understanding and mutual comparison of views—something we shall touch on later—this in itself does not create the logical problems we shall discuss. Those arise from the very attempt to formulate total views—to treat everything as objectual.

A connection that one finds or postulates may be loose or tight; the specific parts of a context may be more or less autonomous and independent from one another. The connection that one speaks about may be thought to apply to a number of things that are of interest at the moment (for example, prices or demand and supply as regards the paintings of Edvard Munch, and so on). Then one does not pretend to have said anything at all about other things and their connection or lack of it. On the other hand, the context spoken about may conceivably cover the whole life of a human being, or life in general. We encounter difficulties when we try to say something about everything, as well as when we try to say something about a thing that has been abstracted from its context.

Before a life can be subjected to evaluation, it has to be examined as a whole. Does that whole, however, involve self-evaluation? At least not the same whole, one might say.

Evaluation of life is different from life itself. We are concerned about two different wholes. There is nothing paradoxical here. All our everyday reasoning and action give the impression of wholeness, even if they are not manifested as an explicit and consistent total world picture. Such an underlying unity must be presupposed if actions and arguments are not to seem senseless and pointless. This connection with other mutually confirming arguments, beliefs, and attitudes is present even if a person is entirely ignorant of the underlying unity and is perhaps unable to verbalize the complicated network of interdependent parts. This merely means that everyday human activity reflects a frame; hence, it may be regarded as a whole.

There is, however, something strange and paradoxical about the non-mundane philosophical activity of constructing systems that distinguishes

it from the more or less structured activities in everyday reasoning and action. Philosophical systems seem to be attempts to consider and articulate everything (activities, life, and the evaluation process itself). How can the unity that is basic to the activity of a system builder be considered, and made explicit, within the world picture that is the result of his own activity? Like any activity, especially any reasoning activity, system building requires certain rules. The system creator assumes a framework. Certain presuppositions are accepted, even if only implicitly. It is difficult to imagine how the system, which is indeed the product of these rules, incorporates independent presuppositions.

If we are interested in the study of foundations rather than superstructures, and the presuppositions rather than the conclusions of a dogmatic system, then our interest will involuntarily turn away from the explicit toward the implicit. If, for example, we examine an argument we have employed to justify that we know something and find that it does not satisfy the demands we had posed for justifying knowledge, then we discover how lenient our implicit criteria of knowledge were. When we become aware of our oversight, we may then investigate the stricter requirements that made us condemn our earlier argumentation as careless. Perhaps these requirements are also not strict enough? Perhaps they are too strict? Perhaps our initial procedure was not so bad after all? It is not impossible that a transition to a wider or larger frame may make us sceptical and uncertain regarding our previous sceptical worries concerning our original irresponsibility.

This shift of our attention from frame *A* to another frame *B* that also contains *A*, takes place within a new implicit frame where one may imagine making both frames *A* and *B* explicit. As we retreat in the chains of presuppositions, we immediately and unavoidably move from one frame to the next in a regressive series. Attention may then turn to frames of reference and thereby to the foundation of our whole way of posing the problem. The following questions arise: Why not get rid of the frame as well as the problems? Do we really have, and do we employ, an implicit frame of reference? How did this idea get involved in our considerations? What presuppositions did we use at this point?

Such reflection on frames of reference exemplifies how we can clarify our own presuppositions when we try to become clear about those of others. This thinking is itself a legitimate subject, and since this way of thinking is only an assumption about the nature of our methodological convictions,

then perhaps we can do without it, even if we cannot do without the methodology. It does not seem likely, however, that abandoning this terminology will lead us any closer to answering the questions that necessitated it.

We seem to be caught in a trap, unable to free ourselves and unable to start anew. We can examine all the beliefs we had until the moment of examination, but we never reach the critical examination itself. It is tempting here to quote Kierkegaard's wonderful rhetorical reflection in his main philosophical work *Concluding Unscientific Postscript* (1941) about "the System," but here are the essentials: The System begins with the immediate, and is therefore without any presuppositions whatsoever. The beginning is therefore an absolute beginning. But does it start immediately with the immediate? Kierkegaard finds that impossible. So what does the System really start with? Kierkegaard suggests that it starts with the reflection, existential reflection. And then he asks: How could one end the reflection and start with the System?

We mentioned how the all-encompassing character we try to give a frame is made explicit by a collection of basic beliefs or assumptions. The inescapable retreat into frames of higher order and the succeeding infinite regressions suggest that it is impossible in principle to formulate all basic principles of this all-encompassing kind. The whole eludes what we grasp and formulate in discursive thought. Just as we cannot inflate a balloon from the inside, we cannot examine a set of methodological beliefs without employing another set of beliefs. In order to examine one belief, we must do something analogous to blowing new air in from the outside, meaning that we must introduce or employ principles other than the ones we examine at the moment. In the regressive process of examining frames of reference, something eternally eludes us. (Of course this applies to the latter claim as well because it can also be subjected to critical examination. Parts of the frame of reference can be clarified, and implicit assumptions can be made explicit.)

The notion of fundamentality is itself a relational concept. We use our existing fundamental views to probe the set of views that are implicit in our first-order investigation, to build on the explicit elements of our first-order views to examine second-order views, and so on—*B* is basic or fundamental in relation to *A*, and *C* is fundamental in relation to *B*. If fundamentality is a relational concept, however, then the quest for a natural point of departure is no more realistic than a journey to reach the horizon.

The explicit total views that we find in the history of philosophy are fraught with paradoxes. Either a view is explicit but fragmentary, or it is total but implicit. If one considers the usage of the word *view*, one may arrive at a similar conclusion. A view is something from a place, and this place is not part of what is seen. One cannot have a total view in the sense of a view that comprises the view as well as the point from which it is seen. Perhaps it is only after philosophers and others attempt to work out gigantic systems that we ask, What makes system builders with “totalitarian” aspirations believe in the possibility of reaching their goals? It is only after considering what seem to be inescapable paradoxes or contradictions that we can begin to talk about conceiving the sort of preconscious views or inclinations that we must have before making philosophical investigations.

At this stage we must ask three main questions: (1) What kind of totality should we ascribe to a total system that cannot be completely explicit? (2) How can we explain the great philosophers’ belief in the possibility of total views? (3) What are the consequences of the unavoidable incompleteness of any explicit total view for the representation, survey, and comparison of philosophical systems?

In what follows we focus on the last of these three questions. First, however, let us consider briefly how we might answer the first two. A possible response to the first question has been suggested. Perhaps we should assume, as a counterpart to the explicit system elaborated by a philosopher, the existence of a basic preconscious view or orientation — a kind of matrix that is the basis of all attempts at investigating and explicating the concepts and categories in any implicit frame of reference. Since such a “view” could not itself be made explicit, it would not be a part of what could be investigated in this manner. This conception of the “totality” of a view would at least prevent the type of leakage that seems to result in any system in which an explicit methodology presupposes still another methodology, which then has to be made explicit, and so on. For if the explicit view arises from a preconscious matrix, then what it excludes is not something that it ought to include. This might tempt us to say that whatever can be clarified by means of concepts and categories in a certain way is an expression of the preconscious view that cannot itself be clarified in this manner. It then becomes questionable, however, whether we should call it a preconscious view at all. The word *view* suggests something that can be maintained and examined, which again implies the possibility of making it explicit. If the pre-

conscious is not regarded as a view, it would perhaps have to be considered as the cause of the explicit system, as its psychological foundation. We shall not pursue these questions further.

What about the second question regarding how belief in the possibility of explicit total views has arisen? This question may be phrased more precisely: How can it be explained, from the point of view of psychology or social science, that man has begun to speak or come to believe that he has spoken, or can speak intelligibly, about his total view, his logic, ontology, epistemology, and value system? How have we arrived at the possibility of contemplating our own total view as one among other views that can be made explicit?

Perhaps the belief has developed this way: We believe we notice that a particular human being always thinks and believes in a certain way (of the many possible ways we can imagine). The set of possibilities is implicitly fixed by our own — the observer's — frame of reference. To express as clearly as possible what distinguishes our view from that of others, we seek not only to make their views explicit, but also to make our own explicit. We tackle the latter as if it were identical to the former — something that already lies within our own frame. We are not fitted into our own frame, however, and this makes the second task completely different from the first. To perform it seems to me to be just as difficult as eating not just a part of oneself, but the whole. The analogy that makes one believe in the possibility of such an explication is fortuitous. A view that comprises other views does so by fastening the different views that it comprises to something else, the adjusting view. However, this latter view in its turn can be explained only by being adjusted in the same way, by being fastened to another something else.

Since the considerations about another person's views must be conceptualized within our own frame, our own views will also be in that position. Because we are primarily interested in contrasts, the part is mistaken for the whole (i.e., one's own fundamental conceptual framework tends to be overlooked). The same applies to another possible way in which this belief can arise, namely by looking back at earlier parts of one's life and attempting to investigate them. As Arthur Koestler reminisces, "My Party education had equipped my mind with such elaborate shock-absorbing buffers and elastic defenses that everything seen and heard became automatically transformed to fit the preconceived pattern" (Koestler 1949: 60).² One need

DESCRIPTIONS OF MAXIMALLY COMPREHENSIVE PERSPECTIVES

only take a small step away from the belief in an all-encompassing knowledge of one's own mind as it was at an earlier stage of development to imagine that one has at that moment a definite all-embracing view, which can be made verbally explicit as one view among others.

Within psychology, as in other sciences of humans, there have been conceptions of all-embracing views, and it has apparently been taken for granted that they were to be used in research in order to produce satisfactory neutral classifications of individuals or groups. Let me quote from one who has a strong belief in all-encompassing outlooks:

Our revised, more dynamic and concrete conception of an ideology may now be defined as the complete system of cognitive assumptions and affective identifications which manifest themselves in, or underlie, the thought, speech, aims, interests, ideals, ethical standards, actions—in short the behaviour—of an individual human being. (Walsby 1947: 145)

Walsby's belief in an underlying ideology has striking similarities to the belief in a God who manifests himself in everything that happens in the world. There seems to be a strong Hegelian tendency in ideology research, influenced by Karl Mannheim's comprehensive concepts. In his *Ideology and Utopia*, Mannheim writes, "Here we refer to the ideology of an age or a concrete historico-social group, e.g. of a class, when we are concerned with the characteristics and composition of the total structure of the mind of this epoch or of this group" (1936: 49 f.).

The ideology of a person that Walsby might wish to observe would have to be described and classified in relation to a frame so all-encompassing that it completely comprised the observed person's frame. The ideology of an age or a particular historical social group, such as Mannheim observed it, must at any point be surpassed by—be contained in—the ideology of Mannheim's group or age. The all-encompassing structure of Professor Mannheim's own mind must, in the same way as a divine intellect, provide a frame of reference and a conceptual structure of the most all-inclusive or value-neutral type. Concepts such as these are mighty factors in the construction of the images of fascists, communists, and others who cannot be reached via ordinary lines of communication because their basic views differ from those of the observer. One cannot discuss with them, but they understand the language of power.

Walsby presupposes, on the one hand, that the people he observes are developed comprehensively (so that their ideology can be derived) and, on the other hand, that their views can be understood by a nonspecialist. What is the outcome if by mishap one catches a logician in the net, for example, Professor Benson Mates? Before rejecting him as nonrepresentative, one would have to consider what he says about philosophical opinions—indeed, they are parts of the ideologies. Mates (1968) asks if, within a system that is approximately all-embracing, problems can arise that threaten its foundations. Unsolved empirical problems cannot threaten the foundations since they have an open character. If one constantly finds the opposite of what one expects (empirically), there is room for any conceivable change in the empirical hypotheses. Logical problems, it seems, may cause fundamental crises.

According to the logician and epistemologist Mates, we may consider such a crisis to be present today. This suggests that we should look for new foundations—a new set of basic logical concepts. Mates takes the logical antinomies as his point of departure. By “antinomy” he means an argument that has a logically false conclusion, yet seems to be valid, and has only analytical truths as premises. Examples are the liar³ and Russell’s antinomy.⁴ Mates does not expect that any intuitively evident solution will ever be found. He believes that, after 2,400 years during which philosophers have examined the liar, the proposed “cures” are still worse than the “illness.” The main difficulty is not a lack of powerful arguments; on the contrary, it is the existence of excellent, logically watertight arguments both pro and contra.

Mates suspects that a series of philosophical problems—free will, the existence of an external world, and so on—are such that the more precisely they are posed, the closer we come to ending up with contradictions that are equally well justified. The more precisely the problems are posed, the more apparent their antinomical character becomes. The conclusion is that if we put them together in suitable groups, some of our most basic concepts are radically defective.

It is difficult to say what we can do in such a situation. Mates thinks that the only cure is to “forget it all,” in the spirit of Hume. Imre Herman, Lucien Lévy-Bruhl, Mannheim, Walsby, and many others have no doubt that the fundamental convictions and attitudes of others—for example,

their logic — can always be described and compared.⁵ In cases in which the all-embracing description is directed at so-called primitives, the observer is seldom exposed to a reversal of roles; the primitive merely ignores the scientist's total view. If, however, the social scientist is confronted with critical or enraged adherents of systems that are not verbally primitive, then he will become conscious of some of his own assumptions, and he will speak about, or believe that he can speak about, his own basic frame of reference. In the course of rationalizing his implicit assumption that he can discover and satisfactorily describe the total views of others, he can be led to believe that he also has a total view that is capable of being verbalized. That which he more or less uncritically ascribes to others, he now feels compelled to ascribe to himself. He insists that he has a total view and is willing to verbalize it, using terms such as *the world*, *man*, *freedom*, *progress*, and so on.

It is tempting, even if the method annuls itself, to apply Heidegger's system when one seeks to characterize the attitude of philosophers and scientists who unhesitatingly and unreservedly give all-embracing descriptions of ideologies, total views, and philosophies, primitive or not primitive. Heidegger writes about the way of being when "das Man" has the upper hand, and one is generally comfortable with it in its very degeneracy (*Verfallenheit*):

Prattle (*Gerede*) and ambiguity, the having-seen-all and having-understood-all — builds up the assumption that the openness of *Dasein* accessible in this way can guarantee *Dasein* that all the possibilities of its being are secured, genuine and unfolded. The self-assurance and resoluteness of *das Man* spreads a growing frugality as regards actual "personally" appropriated understanding.
(Heidegger 1927: 177)

Formulation of Systems

System Concepts

The term *system* will be used somewhat loosely to describe sets of propositions, rules, or postulates that are in part explicit and in part implicit and that purport to cover a large and essential part of all possible kinds of objects of thought and imagination. The system may be said to be total when it is intended to cover all such parts. Something can be represented by a system, although not everything that can be said about this "something" (the

object) is said. Plato's theory of forms covers all forms without saying something about each one. Newton's theory of matter covers all material particles without saying anything about a single one of them.

The representation of "system" is intended to ensure that what is traditionally characterized as a system in the history of philosophy can be subsumed under this designation relatively unproblematically. Of a person, group, or nation, we sometimes say that she or it has a general or total orientation toward existence. We contrast such general orientations with attitudes toward a limited phenomenon or a limited aspect of reality. We speak of views of existence as a whole as total views or total systems. For professional reasons, the word *system* is preferred over view.

Since Aristotle, we recognize attempts to verbalize general orientations in the form of long series of formulations that seek to cover all subjects. These general orientations, however, do not appear in the form of detailed knowledge: one seeks to express only the vital or essential aspects of categories of thought. One has not restricted access to new material, but one has predetermined its categories. If something occurs that defies the divisions, the system bursts. If, however, the system is "sufficiently total," such a thing cannot occur. We will return to this point later.

Philosophical vocabulary includes words that, besides having other uses, characterize general orientations: rationalism, pragmatism, materialism, Spinozism, Hegelianism, and others. These catchwords are useful for our deliberations as long as we remember that they are adapted to the *history of ideas*, not the *systematization of ideas*.

Some systems are explicitly presented as systems (Aristotle, Hobbes, Spinoza); others are not. Among the latter, there may be explicit rejections of philosophical system construction (Sextus, Hume, Kant, Wittgenstein). It would lead to unfruitful distinctions to exclude total orientations to existence, verbalized but "antisystematic" thoughts about all essential subjects, just because they also contain direct antisystematic statements. If system *A* answers 1,000 questions and system *B* consists of arguments connected to each of these questions with the conclusion "pseudo-question," *B* has indeed a very negative character, but this is not sufficient reason to deny that it is a system.

It is another matter with Sextus Empiricus and Pyrrhonism as he represents it. Pyrrhonism contains no assertions at all. The possibility of knowledge is not denied. The Academic sceptics, on the other hand, deny the possi-

bility of knowledge. Therefore, they are involved in arguments committing them to acceptance of propositions, and we may speak about an Academic-sceptical system (provided the possibility of complete consistency is accepted). As a questioner, in relation to others and himself, the Pyrrhonic philosopher participates in discussion, but not as one who asserts anything. There is a Pyrrhonic philosopher but no Pyrrhonic system.⁶

From Socrates' time to our own century's Rudolf Carnap, Ludwig Wittgenstein, and G. E. Moore, antisystematic, but nevertheless approximately total, verbalized orientations have existed. In what follows, the primary focus will be on the more or less explicit system constructions.

To understand philosophical systems, we must keep the pretension of totality (*Ganzheitsanspruch*) clearly in mind. The philosopher's struggle to gain an entirely sublime perspective, his striving to avoid the fact that something hides behind his back and may thereby remain invisible, must necessarily put its stamp on much of his work. Thus, abstract ontological reflections may acquire a weight that must seem incomprehensible to anyone except the totality-seeker himself. Bertrand Russell's monograph about Leibniz (1937) illuminates the importance of seeking out precisely the decisive problems of the system creator.

In the preceding, the word *orientation* is often preferred to *belief*. As I construe it, an orientation also comprises one's attitudes toward what one believes. Furthermore, an orientation can encompass beliefs. Hence, the word *orientation* in the preceding is meant to express a more general concept than 'belief', and to emphasize something active that involves both subject and object.

In his doctrine of philosophical systems, Everett W. Hall (1960: 1) assumes a rather wide concept. By "philosophical system" he means something like a "set of categories." This is hardly a satisfactory point of departure. He uses "category" in a sense close to the *Oxford English Dictionary's* second, extremely wide definition: "a class, or division, in any general scheme of classification" (Hall 1960: 3). Actually, he has no use for such an extremely wide concept. As an example of a system, he mentions the Scholastics' "transcendentals": *ens* (entity), *unum* (unity), *res* (thing), *aliquid* (something), *verum* (truth), *bonum* (good). In our terminology, we would say that these are categorial basic concepts within a class of possible systems. If we connect the concepts and define them in various ways, they

may become limited parts of the conceptual structure in systems defined as on page 10. Differences might arise, for example, by using different definitions of *true*, as these are developed within Scholasticism.

Categories in Hall's sense are not propositions; their adequate verbal expressions are terms, not statements. According to Hall, a system does not need to be expressed as a set of contentions. Such a rule is appropriate if one inserts an "only": an adequate articulation of a philosophical system cannot consist *only* of contentions or propositions. On the other hand, our concept 'philosophical system' is impossible to identify only by using categories. Certain Scholastic systems can, as a first approximation, be articulated by constructing a set of descriptive and normative sentences in which the expressions *ens*, *unum*, *res*, *aliquid*, *verum*, and *bonum* occupy a characteristic position. A group or family of such systems can be characterized by the fact that they are based upon, or make a central use of, these categories. No single system, however, can be exhaustively characterized by them.

For reasons that easily follow from the preceding, we shall therefore not seek to characterize a system definitionally by a set of concepts, a conceptual structure, or a conceptual frame of reference. The requirement that systems must not contain contradictions leads to interesting research problems concerning disciplines that are said by experts within the discipline to involve conflicting presuppositions. Let us consider an example. Many lawyers and philosophers of law have struggled with problems of free will.

One can indeed say that in our conception of law and our evaluations of it, we operate with mutually incompatible presuppositions. In our demand that the law must be just, we presuppose a certain freedom of will. In our demand that the law be efficient we assume that the law, as a causal factor, can create motives and thereby act as a determinant of human conduct. (Castberg 1966: 65)

Experts on "law and our evaluations of it" acquiesce in what they at least suppose is a contradiction, as long as the contradiction cannot be formulated within their field, that is, within the subject "law and our evaluations of it." When the contradiction lies in the *presuppositions* of what is said within the field, scruples of professional ethics do not arise. It is left to others to alleviate the contradiction, for example, to philosophers who specialize in free-will problems. The elimination of the contradiction, if it exists, may be sought by confronting the philosophy of law with a series of philo-

sophical theories and precizations of sentences such as “*x* acts freely,” “*x* is determined by *y*,” and so on. Only those syntheses that yield a consistent set of presuppositions can be integrated in a total system.

According to the indicated use of the term *system*, a system is total if it covers all partial systems. It is here taken for granted that a kind of basic distribution of subjects is possible. If this were not the case, one could not place systems in relation to each other so that they appeared to be possible parts of a whole. A circularity cannot be avoided here: a total system can be constituted only by integrating partial systems, but constitution of a partial system qua partial system can occur only in relation to the idea of a total system. To avoid the specific difficulties involved in the notion of an absolute system, it is appropriate to focus on the movement from less total to more total, hence on the phase of integration in which a system is expanded successively. When the integration reaches a level at which the system begins, in a relatively vague manner, to cover the traditional disciplines of philosophy, most problems of interest to those other than specialists in logic also emerge clearly. Specifically, logical problems do arise (for example, in connection with self-reference: that the system must be applicable to itself), but these problems arise only with attempts at maximal precision and depth of intention.

Following our proposed use of the word *system*, a system is on the level of connotation, not denotation (reference)—the B-level in the Semiotic Triangle. It is something that is expressed by a specific set of texts. This implies that different sets of texts can express the same system. It further implies that in the absence of direct knowledge of the B-level, the claim that a text expresses a system is a hypothesis of a very special type. Recognizing the need to choose a mode of conception and definition within a total system brings us to ask, Can we find a neutral semantics?

We have already begun to choose a semantic metasystem for the study of the semantic characteristics of systems by virtue of characterizing systems as things that exist on the level of connotation (the B-level) and not on the level of formulation (the A-level). At this point, we have probably already lost our neutrality. Some systems may contain semantic part-systems incompatible with our own, and this may endanger our description of the system.

On the basis of the selected use of the term *system*, it is easy to give a preliminary indication of what must be counted as different systems. As soon as the depth of intention increases and we transcend the level of every-

day parlance (the “ T_0 -level”), it turns out to be very difficult to define criteria to describe the difference.

If two sets of propositions, rules, or postulates are presented and at least one proposition, rule, or postulate is different, then the sets are different. If the two sets constitute systems, then the systems are different.

In practice, texts and authorship play a decisive role in our identification of systems. If two different philosophers write two different texts, and we believe the texts express systems, we take it as a matter of course that the systems are different. We tend to treat systems as if they belong on the level of signs or texts (the A-level). To consistently identify philosophical systems with texts, however, leads to even greater difficulties than if we try to restrict them to the B-level. I mention this because a problem is encountered immediately when one attempts to compare sets of propositions, rules, or postulates. By putting “and” or “full stop” between the various propositions, rules, and postulates, we can significantly vary the number of sentences used to characterize a system (on the A-level). The use of “sets of propositions” depends, strictly speaking, on the dubious presupposition that one can in fact indicate all the necessary propositions with a specific number of sentences. If one includes implicit propositions in the set, the situation becomes even more difficult. Implicit propositions are those representatives of the system that may never have been articulated but that would likely be revealed when the system is reviewed in an exhaustive way and contrasted to other systems. Here the indication of particular numbers of propositions must seem highly dubious. For comfort, however, one may limit oneself to defining sets by relations relative to other sets (inclusion, exclusion, emptiness, and so on), and thereby avoid having to specify the number of elements in a set.

Jaspers's Typology of World Pictures

It is not within the scope of this work to give a classification of systems. Nevertheless, Jaspers's attempt to create a typology of world pictures on psychological grounds is so instructive for our questions that we find it important to consider some aspects of it.⁷

Under the term *world picture*, Jaspers includes far more than the products of professional philosophy. The latter, however, are special formulations of something that has a universal basis. Presumably, if one aims at a

DESCRIPTIONS OF MAXIMALLY COMPREHENSIVE PERSPECTIVES

typology, the study of the most refined philosophical culture products ought to take the “more general” for its point of departure. It is well worth the trouble to highlight Jaspers’s typology.

First Main Class: Total Pictures of the Sensible in Space

Jaspers’s types according to Division Fundament No. 1 are:

1. *Immediate World Pictures*. With regard to a person’s immediate world picture at a given time, Jaspers seems to include whatever this person experiences insofar as it is experienced as something outside the person herself, in space. Jaspers gives examples: colors, tones, smells, horizons, and so on. By the word *world*, he presumably suggests a kind of synthesis or combination of these constituents.
2. *Pictures of a Limited Cosmos “Behind” the Immediate*. There are also conceptions of a “world” behind that which is immediately experienced. Such a world cannot be perceived but is perceivable in principle. Every human being creates fragments of a geographic-cosmic world picture. The first systematic pictures are of a limited and finite cosmos.
3. *Spatio-Temporal Infinity*. Giordano Bruno gave us pictures of infinitely many worlds in an infinite space. Jaspers’s acceptance of the infinity of the spatial world did not yet, in 1919, take seriously Einstein’s distinction between infinity and unlimitedness. Today we know, perhaps, that the world is finite but unlimited.

Already by this division, Jaspers has ventured a solution to immense problems. The three types of total pictures indicated here by Jaspers are, strictly speaking, not kinds of actually occurring world pictures, but sides or aspects of something, x , that comprises 1 and 2, or 1 and 3, or 1, 2, and 3.

Today, Jaspers’s doctrine about what is immediate will presumably seem peculiar and rather special. We do not live in the present moment but in something that has a considerable fullness in time. The moment is formed by abstraction. Furthermore, tones and colors do not have the special relationship to the immediately given that psychology in Jaspers’s period assumed. We do not live in a shop where tones, smells, degrees of hard-

ness, and so on are to be found on shelves. Here Gestalt psychology and phenomenological trends have provided correcting insights. Furthermore, *inventorying* the immediately given is not the same as *describing* the immediately given. Here Jaspers encounters the problem of the relationship between living in a certain world and precisely conceptualizing that world. What can reflection and consciousness achieve here? Are we not inhabitants of this immediate world? Furthermore, can the world in which we live be abstracted from our evaluations and attitudes? Jaspers answers no. Under the title "Evaluations" (*Wertungen*), he touches on the plurality of values, noting that value hierarchies vary from individual to individual. If I find Vigeland Park beautiful, that which I find beautiful does not move from Oslo to Paris when I myself move. The beauty is in Vigeland Park, not in me. It belongs to my world picture, to that which I conceive as being outside myself. The same notion applies to a host of other evaluations. Turning to attitudes, consider how an object's utility contributes to our view of the object.

Attempts to draw a distinction between internal and external will have deep repercussions on philosophical problems. These repercussions will manifest themselves in different ways, which depend on what basic philosophical positions are assumed. These efforts will, of course, also vary according to the results of scientific research (psychology, sociology, and so on), which different individuals seek to exploit or ignore.

These critical remarks may make it appear as though my aim is to replace Jaspers's classification, but that is not my intention. The remarks are meant to illustrate difficulties that immediately arise with such distinctions. As soon as they are expressed somewhat precisely, such distinctions can no longer be viewed as philosophically and scientifically neutral.

Attempts to delineate immediate from more reflected worlds, and sense-worlds from conceptions of more or less hidden or merely imagined worlds (for example, worlds in which there are no secondary and tertiary sensory qualities), are nevertheless important for understanding how the search for total systems arises. They remind us that "everything hangs together." The various proposed worlds appear, at least in part, as ethereal or arbitrary abstractions—but abstractions from what? There is a great temptation to answer: from the only concrete and real world. But which one is that? From what world are the different conceptions we have been considering drawn? It is precisely the different conceptions of that world that we

have sought to consider. It is this treatment that first (heuristically) motivated the introduction of abstractions.

Let us now move on to Jaspers's types according to Division Fundamental No. 2. According to Jaspers, three types of world pictures develop by differentiation from the immediate world picture, which contains the seed of all later ones. They are:

1. Nature-mechanical world pictures.
2. Nature-historical world pictures.
3. Nature-mythical world pictures.

The nature-mechanical pictures are nonsensuous; they are construed by abstraction and mathematical analysis. Everything qualitative and intuitive is forced out of the world. Nature becomes something that can be computed and controlled.

The nature-historical world pictures retain the secondary sensory qualities and seek to provide a natural division of the sensuous variety of nature. Jaspers says that loving absorption in individual phenomena (insects, crystals, mountain formations, and so on), a morphological appreciation of everything that is created, is characteristic of this world picture.

The nature-mythical world pictures contrast with the other two (and developed from them) by making room for what the others consider to be "mere" experience, symbolism, mental life, or fiction. The atmosphere of scenery is in the scenery, not in the soul. The atmosphere has object character. "Objectively, phenomenologically formulated, man finds in this world infinitely many connections and analogies, which we know from the whole of history, all the way from the Babylonian doctrine of the connection between the movements of the stars and human destinies: everything in nature stands in an intimate kinship: human beings, stars, animals, plants, organs, minerals, metals" (Jaspers 1919: 161).

The three types of world pictures have become "absolutized" into *philosophical* world pictures: mechanistic (for example, Democritus), naturalistic (for example, Ernst Haeckel), and nature-mystical (for example, romanticism, theosophy, and Gustav Fechner).

Implicitly, Jaspers assumes that philosophy seeks more comprehensive and unified pictures. A demand for a total picture is operative, and it is

strongly supported by a requirement for consistency. In an (unphilosophical) individual, however, the three types of pictures can coexist, each alternating with the other in domination.

In line with Wilhelm Dilthey's view, Jaspers exemplifies the "absolutization" that is common in attempts to form total systems (in my terminology) by referring to Goethe's passionate struggle against Newton's mechanical theory of colors.

Goethe held the mechanical explanation of nature as something absolute, as philosophy of nature, while it was merely an abstracting emphasis of a connection with the purpose of grasping and mastering nature from this point of view. Likewise, Goethe absolutized his own nature-historical procedure and had to fail insofar as he did not recognize the essence of the other procedure. (Jaspers 1919: 142)

Jaspers's view of system differences between Goethe and Newton is itself part of a larger web, part of Jaspers's view of history, methodology, mechanical explanation of nature, and nature-historical procedure. From other "meta-systematic" points of view, such system differences may contrast profoundly. An example is the difference seen from the point of view of Hjalmar Hegge (1967). According to Hegge, Goethe's methodology is based on an epistemologically fundamental position in which man has the capacity of *exact sensuous fantasy* ("eine exakte *sinnliche* Phantasie"), a specific cognitive ability. Goethe's "sensuous fantasy" refers to a form of cognition that must first be developed through the researcher's work with the material of experience. It is not part of his makeup (except as latent talent), but rather is comparable to an *organ* (an expression used by Goethe himself) that is developed, or perhaps, trained, by systematic use. Here, Goethe's view of science is radically opposed to the generally predominant conception in epistemology today.

Jaspers suggests that a (nearly) total system must contain all three pictures — a very daring position from the standpoint of the doctrine of systems.

The fight about the world pictures always begins only with the absolutization, that is, when a world picture will apply to everything and for everybody: nature is not only a dead mechanism, not only life, not only mythical world. It is everything, but only for the one who looks positively and the one who exclusively looks at the moment, not for the one who denies, the one who takes from each standpoint merely the no in relation to the others. (Jaspers 1919: 143)

This seems very convincing—a speech in favor of the open mind that makes room for everything. The positively oriented person in Jaspers's terminology, however, is not yet a philosopher, and maybe he is right in abstaining from such attempts. For it is precisely the attempts to integrate the three types that lead one to interesting difficulties. The absolutization that Jaspers mentions can be reflected or superficial. In the deeply based absolutizations, room is sought for all three pictures, but within the frame of a single total view. Consider the atomic theory of antiquity which contains the doctrine of mental phenomena as especially smooth atoms. In this theory, atoms cannot be identified as corporeal or material. An atomic world with only smooth atoms contains only souls and gods! Even if all atoms have extension, this does not entail corporeality. The atomic theory provides examples of "absolutizations" of the nature-mechanical world pictures wherein *everything* sought is encompassed. Analogous examples can be given for the other two types.

All models, however, are restricted in their accuracy. No model or method can justifiably claim to be regarded as fundamental or all-inclusive. This relativity is itself relative. It can be denied without inconsistency; the nonrelative standpoint is not, however, thereby reestablished and stabilized. This was my position in *Erkenntnis und wissenschaftliches Verhalten* (Science as behavior):

We believe that all models and methods must have a limited range of application and that they are most effective within this range. We have strongly emphasized the relativity of models in connection with subjective models. We can now emphasize that in our opinion behavioral models are just as relative as the subjective ones.

Our asserted relativity is also relative. When someone objects that the argumentation is either too unclear to be disproved at all, or leads to an infinite regress, then we answer: Indeed, if we both assume fixed models where (1) infinite regress is definable and (2) a prohibition against *regressus ad infinitum* is derivable—or if we both accept the same criteria of clarity. Perhaps we finally agree and accept the same models and criteria, but perhaps we don't agree!

If we disregard a model's relative unsuitability as a means to solve specific tasks at hand in an appropriate way, then any suitable model can justifiably claim universal applicability. In this sense any method, any attitude that serves to master a situation, can give occasion to an all-inclusive absolutistic system. It is merely a question of applying sufficient time and fanaticism to it.

(Naess 1936: 247–48)

Hence, we need a concept of absolutization that is evaluationally neutral—a concept that covers, in principle, a completely defensible generalization or extension of propositions or postulates with respect to a range of applications. From intended validity within a partial area, or from an aspect, one generalizes to unrestricted validity.

*Second Main Class: Total Pictures with
Point of Departure in the Mental and Cultural*

Jaspers depicts the following constituents:

1. The individual's own immediate world.
2. The world of the other and the stranger.
3. The infinite world of the intelligible.

Jaspers illustrates the individual's immediate world by referring to the fact that we construe meanings and motives as something perceptible and objectual: we understand or misunderstand people, actions, and works of art. (We note in passing that misunderstanding is by no means the least interesting and revealing form of understanding.)

We also seek to immerse ourselves in the worlds of others, in other cultures. We consciously seek to see things from points of view that are foreign to us. Our world can expand to comprise, *inter alia*, spiritual, logical, aesthetic, religious, and political spheres. The potential for expanding our perspective is limitless, but it necessitates becoming aware of our own perspective's relativity.

In the world picture of the infinite comprehension there are unlimited possibilities for experiences and cultural contents for man. One sees the limitation and relativity in one's own mental and cultural existence, insofar as this has objective form.
(Jaspers 1919: 153)

So much material and so much comparison can render our own existence problematic and deprive us of our instinctive will. The enormity of such a project may lead to internal submission and to satisfaction with contemplation and inauthenticity. If the historical and psychological world picture is absolutized on the basis of such tendencies, one speaks of *historicism* and *psychologism*. The person who becomes addicted to such absolutization may be

DESCRIPTIONS OF MAXIMALLY COMPREHENSIVE PERSPECTIVES

characterized thus: Instead of arguing, he understands and explains. Instead of choosing, assenting, or opposing, he passively acquiesces in everything effective because it is effective. He refrains from any evaluation (Jaspers 1919: 158). These words are well worth considering when one tackles an investigation of world pictures *en gros*. Absolutizing historicism and psychologism is then close at hand. In Jaspers's own case, his typological endeavor did not lead to any philosophical self-renunciation. We note that Jaspers's typological endeavor was not performed with a purely descriptive aim either: Jaspers selects and discards, recommends and deprecates, gives praise and blame. He does not pretend (or should not pretend) to be evaluationally neutral. In that respect, the title *Psychologie der Weltanschauungen* is misleading, as Jaspers suggested in the preface to a later edition of his work.

Third Main Class: The Metaphysical Total Pictures

Types divided according to *content* are:

1. Mythological-demonic world pictures.
2. Philosophical world pictures.

These types can be further divided into:

- a. Absolutizations of some concrete world pictures.
- b. Rationalistic and pan-logistic world pictures.
- c. Negative theologies.
- d. Mythical/speculative world pictures.

In addition, philosophical world pictures can be subdivided according to a particular philosopher's ways of thinking:

1. Beholding types.
2. Substance-directed way of thinking.
3. Formal way of thinking.
4. Ordering/receptive way of thinking.

According to Jaspers, metaphysical world pictures are those that "concern the *whole* and the *absolute*" (1919: 161). The metaphysician responds to

the question “What is the actual, ultimate reality?” Plato answers by referring to the realm of ideas: the sensible world is unreal, or not of the highest degree of reality.

In the mythological-demonic world pictures, people *live*, “one does not ask intellectually.” These people provide intuitive background through myths about the world, about the origin and destruction of gods, and about obscure forces that form our destinies. In contrast to the mythological-demonic world pictures, the philosophical ones, according to Jaspers, are characterized not by depending on authority, but by appealing to the individual’s own original experience. The picture is sought empirically and is justified intellectually.

Absolutization of mechanism, naturalism, psychologism, and historicism gives rise to philosophical world pictures that can be divided into two types: those that take the object for their point of departure (materialism) and those that take the subject for their point of departure (spiritualism). In the rationalistic and pan-logistic world pictures, outlines of the connections between our views are absolutized. Instead of saying that everything is either stuff or something else perceptible, one says that it is logos, number, being, becoming, and so on. Jaspers himself construes a metatheory, perhaps on a Kantian basis, with “forms of connections of our views.” Regarding the opinions about the absolute itself, Jaspers believes that Hegel has provided a clear survey:

The absolute is Being (Parmenides), is Nothing (Buddha), is becoming (Heraclitus), is quantity (Pythagoras), is object (Leibniz, monad), is substance (Spinoza), is subject (Kant, Fichte). For Hegel himself the absolute qua spirit is all of this, each exists merely as moment. (Jaspers 1919: 174–75)

This quotation shows, rather dramatically, what the result may be when one thinks it is possible to stand above the systems and describe them objectively and clearly, both as they themselves were intended and within one’s own supersystematic frame. Everything is perspicuously ordered by a small set of words that the metasystematician presumes the reader will understand in the same way he does.

There is, however, scant reason to believe that such a supersystematic conceptual framework can be ferreted out and made precise. Such surveys of all intended absolutes can be comprehended only as long as one is permitted to float on the purely everyday associations of the words *be*, *not*, *become*,

number, object, and so on. As far as I understand, however, such a level of comprehension is inadequate. This becomes apparent when one immerses oneself in the writings of any particular philosopher: the more deeply one penetrates, the more one manages to see *everything* from this one system—provided the philosopher actually intended a view that concerns everything. Other philosophical attempts will then either not be perceived or will find a place within the frame in which one immerses oneself. Hence, an opportunity for fully coordinating the different systems does not seem to be present; not if one seeks to move from word to word-meaning, sense, and concept. As long as one keeps to the very wording in “Spinoza means that the substance is the absolute, not being, nothing, world, and so on,” one can obtain a kind of superficial understanding. If, however, one asks, What does the word *substantia* stand for in Spinoza’s thought?, the intelligibility of the schema diminishes until it becomes more or less meaningless.

In relation to Jaspers’s exposition at this point, I shall, in conclusion, only pose the question “What basis does Jaspers’s account rest on?” Does a statement such as “Spinoza takes the substance, not the object to be the absolute, Leibniz the object, but not the substance” make sense if one assumes plausible interpretations of their writings? Can such a comparison be undertaken at any level other than a superficial one?

The third kind of philosophical system, according to Jaspers, is the “negative theology.”

The thinker constantly experiences that, when thinking, he turns that which he thinks into object, thereby delimiting it, and that by virtue of this he no longer retains the totality: the object of his thought has become finite. These inescapable characteristics of the rational constantly become conscious, and so the totality of the world picture ends with merely *negations* and *paradoxes* being asserted about the totality. Thereby one withholds from knowledge that which is reserved for experience, appropriation, and faith, that which is inexpressible, unknowable, but which becomes symptom of forces in man and gives the direction to his interminable endeavor. By its form this world picture is only pure reference without content (Cusanus’s *docta ignorantia*), in ancient theology as in Kantian philosophy, however different these worldviews can otherwise be.

(Jaspers 1919: 175)

The point of departure for the negative theology, as Jaspers describes it, seems very special. This is because one must already operate with specific

kinds of concepts and postulates before one can justifiably assert that certain characteristics of the rational are unavoidable and that the only possibility left for statements about the whole consists of negations and paradoxes. This is not meant as a criticism of Jaspers's division, but as a reminder that all the conceptual demarcations ('rational', 'the whole' or 'totality', 'subject', 'object', 'paradox', and so on) and methodological postulates or axioms must be presupposed *before* one can, on a rational basis, accept or reject such a division. Jaspers presupposes acceptance of an enormous conceptual apparatus.

The fourth type of philosophical system, the mythical-speculative world pictures, is viewed by Jaspers as closely related to the negative theologies. (Jaspers uses only nine additional lines to discuss them.)

Finally, Jaspers subdivides the world pictures according to the ways of thinking (*philosophische Denkungsarten*) that are manifested in the pictures. The beholding type is the most original and uniform. The substance-directed is the most creative with respect to conceptual richness. It seeks, above all, logical justification and coherence. The formal becomes empty because the subject and "the personal-philosophical existence" become unimportant. "From a thoughtful, worldwide mastery of the achieved and acquired arises a scientific school activity that has a strange ambiguity: modest and omniscient" (Jaspers 1919: 187).

With this brief rendering, the reference to Jaspers's rich and instructive work must be concluded. It is regrettable that the line that Jaspers has taken up with so much energy and insight has not been continued. Typology of worldviews is a central concern for systematicians as well as for historians of philosophy, and, presumably, it cannot be pushed to the periphery of psychology and social science for long, as is now the case.

For the central problems of this book, Jaspers's work has significance as support for the following points of view:

1. Even though philosophical systems have many peculiarities in aim and execution, they can be adequately understood only against a broader background, namely worldviews. Fundamental ideas and points of view, and also ultimate aims — systematic and personal — have had and presumably will continue to have their origin in worldviews. As an example, consider Spinoza's struggle for clarity

in the matter of worldview, which brought him into purely philosophical lines of thinking. His *Short Treatise* on God, man, and man's happiness still contains much material that prophetically addresses the mythical and religious aspects of life. Using a purely philosophical treatment, and emphasizing logical consistency, Spinoza transformed the ideas of the *Short Treatise* in the *Ethics*. The *Ethics* is a monumental work of a purely philosophical character, but it is presumably incomprehensible unless it is investigated in its genesis from the point of view of history, history of ideas, biography, and logical systems.

2. Worldviews are immensely varied and exhibit so many differences that one must be exceedingly careful with generalizations. The latter may be regarded most fruitfully as camouflaged research programs and working hypotheses, without sharp demarcation.
3. Any schema, *fundamentum divisionis*, that aims at a relatively precise survey and ordering of philosophical systems must be neutral in relation to the contents of the systems that are to be classified.
4. Lack of neutrality does not reduce the value of the divisions as long as it is not concealed.
5. The more a division formulation is vague, imprecise, or phrased in general terms, the less obvious is any lack of neutrality.

The Goal Is to Exhibit the Difficulty and the Possibilities of Constructing Systems

In the following, I shall try to clarify a selection of difficulties involved in formulating systems. We shall first concentrate on giving examples of "verbalized total views" or "outlooks" and call them, in short, systems. Again and again, attempts at clarification miscarry owing to lack of examples, lack of something that illustrates "the kind of animal" that we are talking about. It will soon become clear that this deficiency is not easily alleviated. On this point, too, we must capitulate to some extent.

The thought of drawing examples from textbooks on the history of philosophy immediately suggests itself. These books offer a basis for condensed representations of the systems of Aristotle, Descartes, Spinoza, Hegel, and others. Starting with pretensions of objectivity, however, one

becomes easily overwhelmed with uncertainty trying to interpret the original intent of systematicians. Furthermore, one cannot avoid the fact that even highly condensed representations become rather complicated. Therefore, I must, at this stage of my account, give up the pretension of fully understanding the total view of any other particular human being. Absolute accuracy of historical details must not be pretended. It is enough for my purpose to sketch systems.

The Function of Philosophical Debate

Adherents of a particular system tend to believe that there could exist a representation of the system that is complete in the sense that it provides the key to the system's answers to all essential questions. This may mean nothing more than that the system can provide answers to essential questions posed from within itself. The outsider will ask for a road map to the terminology of the system, to the very question formulations as they are interpreted by the system's defenders. Without guidance, however, the danger of misunderstanding is imminent.

Misunderstandings may be unraveled by philosophical debate. It turns out in practice, however, that it is very difficult to engender highly objective and professional debate on a highly objective and professional debate. Since a philosophical system is not only comprehensive but also seeks to go to the bottom of things, the individual who is strongly engaged with a system will also look through that system's spectacles and listen through its ears. This difficulty may become acute when the talk is of other systems, other principles, and other possibilities. No question formulation can remain truly neutral. Nevertheless, contributions to the discussion have presumably often had a clarifying effect at certain points. A contemporary example is Bertrand Russell's discussion with Frederick Copleston about the formulation "Everything must have a cause" (1957). Russell's system contains a principle of causation that only requires each thing or event to have a cause, whereas Copleston's principle also requires a cause for everything considered collectively (God). A system difference was clarified at this point. Another example is found in Heidegger's (1949) *Letter on Humanism*, in which he succeeds, to some extent, in clarifying a profound difference between his and Sartre's views of man.

When one attempts to judge the degree of clarity with which a system difference is delimited, one's hypotheses about the definiteness of intention and the level of discrimination within the systems will play key roles. Less potential for discrimination implies less potential for clarification. One may have a high level of discrimination but a low level of definiteness of intention, which also yields a low probability for clarification. A characteristic common to the great systematicians, however, is their formidable depth of intention, be it explicit or assumed.

If one philosopher is strongly influenced by another, the representation of his system can often be uniquely coordinated, in terms of subject matter or chapter by chapter, with the other representation. Spinoza's enumeration and characterization of "feelings" in the *Ethics* corresponds to Descartes's enumeration and characterization in *The Passions of the Soul* (1649). Their doctrines, however, are not identical. Differences appear between Spinoza's concepts of 'passiones' and 'affectus' and Descartes's 'passiones', and there are further differences in definitions and characterizations of the single "feelings." I put "feelings" in quotes because it is a purely conventional translation. Besides, the English word *feeling* cannot possibly stand for Descartes's and Spinoza's concepts.

If one seeks an exact, point-by-point comparison between the two philosophers' doctrines about particular passions, one must try to supplement their accounts with two new chapters that answer the questions "What would a Cartesian description of the kinds of phenomena that Spinoza calls *affectus* and *passiones* look like?" and "What would a Spinozistic account of the kinds of phenomena that Descartes calls *passiones* look like?"

Generally, let us assume that philosopher *A* has a doctrine about a subject that he designates *K* in the form of a series of theses that all contain the term *K*. Let us further assume that philosopher *B* also has such a theory. The system comparer is then primarily interested in four accounts. First, we must consider *A*'s doctrine about what *A* refers to by the term *K*; let us call this *A*'s doctrine about *K_A*. We also have *B*'s doctrine about what *B* designates by the term *K*, hence *B*'s doctrine about *K_B*. Next, we must consider *A*'s doctrine about *K_B* and *B*'s doctrine about *K_A*. If *A* and *B* have explicit doctrines about these subjects, the case is in principle relatively straightforward. If they do not, a comparison of *A*'s and *B*'s systems, topic by topic, will require the construction of two accounts in *A*'s and *B*'s "spirit." Only

as an improbable special case, in which A and B refer to precisely the same K , hence where $K_A = K_B$, or even ' K_A ' = ' K_B ', can the system comparer be content with only two accounts. Normally he gets to analyze four:

A 's doctrine about the topic K_A

A 's doctrine about the topic K_B

B 's doctrine about the topic K_A

B 's doctrine about the topic K_B

The person who seeks to compare two systems without accepting either of them as an adequate basis for the comparison must then himself supplement even the most thorough and original representations. A debate between living representatives of the two systems seems to be the richest source of supplementation. Such a debate, however, can seldom be realized.⁸

It is easy to provide examples of how such a profound comparison can become impossible after only a few steps of precization. For example, what exactly is the relationship between statements about "substance" in the works of Spinoza and Leibniz? If the inquirer is demanding precision, he must envisage answers involving systematic reconstructions of both Leibniz's and Spinoza's systems.

Special complications arise in connection with certain topics, such as semantics. If K_A and K_B are semantics with diverging rules for interpreting philosophical system formulations, a question arises as to whether the semantics used by the system comparer in his comparison of A 's and B 's texts is neutral in relation to K_A and K_B . The question of whether the two semantics differ from each other leads at once to difficulties when one demands an exact answer. For, if one reads K_A first and applies it to the representation of K_B , one will probably interpret K_B differently than if one had begun with K_B straightaway. In other words, insofar as K_A is a general semantics, it covers B 's text as well. From the point of view of K_A , the conclusion is perhaps that B 's text expresses a semantics K_B that contradicts K_A at points a, b, c , but not d, e, f . Correspondingly, from the point of view of K_B , the conclusion by application to A 's text is perhaps that the semantics K_A contradicts K_B , but only at points d, e, f , not a, b, c .

Spinoza has, in part, very peculiar conceptions in semantics. If one employs another semantics, one has perhaps already broken with Spinoza's sys-

tem, but how is one to avoid this situation in setting up a comparison with Leibniz? Leibniz may legitimately demand to be judged on the basis of his own semantics, not Spinoza's.

These difficulties appear when one attempts to give an account of what two systematicians separately assert about something. Of course, new difficulties arise if one goes on to ask about the truth or validity of what the two systematicians claim.

Rules for Extremely Simplified System Presentations

Given our present goal of searching for the simplest and most surveyable system constructions, we shall imagine that the presentations of two systems can be made using a pyramidal form. At the top, as the first tier, one places:

1. All propositions that are not entirely derived or justified by other propositions. These may be divided into two sets: those from which consequences are drawn and those from which no consequences are drawn. The latter possess a peculiar trait of being isolated. We will disregard them in subsequent discussions.
2. All rules that are not derived from other rules but are perhaps justified, for example, in that they are necessary for achieving a particular goal. (The concept 'rules' is construed to include imperatives.)

One class of rules may be omitted, namely rules of usage in the form of definitions. For example, Kant's *Critique of Pure Reason* (1781) contains many sentences that cannot be described as parts of the system itself. It may become essential, however, in the course of discussing various systems, to clarify the precise relationship between such sentences, and in such cases, we shall retain the sentences. Consequently, we must distinguish between statements that are part of some representation of the system and statements that are part of *any* representation of the system.

It is rather common for systematicians to introduce new terms without adequate explanation and to use old terms in new ways without the necessary clarifications. Hence, if one finds the formulation p in one system and non- p in another, the two formulations may not necessarily express different propositions; similarly, if one finds p in both systems, the two occurrences do not necessarily express any agreement.

Simplification Can Generate Misunderstandings: Stepwise Construction of More Adequate Representations

When a systematician seeks a condensed rendering of a system, it is natural for him to select basic sentences and basic rules. It is then left to the reader's imagination and experience to infer what consequences the systematician has worked out. In this chapter, our systems will follow this procedure, although it is obvious that this practice is insufficient. Since ancient times, the Epicurean and Stoic systems have been characterized by certain basic sentences. Unfortunately, many people have drawn erroneous conclusions from the fundamental premises, conclusions other than those drawn by the philosophers themselves. In spite of very different points of departure, the Stoics and the Epicureans ended up with very similar conclusions. Different foundations do not exclude essential similarities in the houses built on them.

If one seeks an immediate and fully adequate comparison of two systems, the systems will become completely unsurveyable. It must be possible, however, to carry out a comparison of systems in phases or stages.⁹ For the metasystematician, then, it is tempting to work primarily with systems that are constructed pyramidally or seem amenable to pyramidal reconstruction. Such projects are far more complex if, however, one cannot indicate basic premises and basic rules. The metasystematician must then seek a kind of listing of "terminal" sentences, which justify but are not themselves justified and which appear as isolated constituents of the system.

It is tempting to attribute a pyramidal character to systems that are unclear and not consistent enough to warrant such an interpretation. The eminent philosopher Ernst Cassirer may have succumbed to this temptation. Consider Cassirer's introductory remarks in his study of Nicholas Cusanus's philosophy:

Any study that seeks to view the philosophy of the Renaissance as a *systematic* unity must take as its point of departure the doctrines of Nicholas Cusanus . . . Cusanus is the only thinker of the period to look at all of the fundamental problems of his time from the point of view of *one* principle through which he masters them all . . . Indeed, all his thought is simply the unfolding and extension of that fundamental first principle developed in his first philosophical work, *De Docta Ignorantia*.
(Cassirer 1963: 7)

If Cassirer is correct, then Cusanus achieved the most cherished dream of many philosophical systematicians. Moreover, if Cusanus did succeed in

this, then presumably others have too—hence the research program of representing philosophies as wholes of the kind that Cassirer thinks Cusanus has realized. The great question, however, is whether Cassirer has not to some extent been deluded into confusing dream with reality. Has he actually — on the basis of the few existing Cusanus texts — accomplished a reconstruction of their contents in pointed, pyramidal form with a well-defined principle on top? Without disparagement to Cassirer, I must emphasize that he only gives suggestions to this. Implementation would require an approach with quite another depth and breadth.

If we are to begin addressing the most far-reaching problems of this work, we must, for the time being, (1) disregard the task of giving an example of a system that is especially tenable or probable. Should a simplification be necessary in order to consider strikingly erroneous statements, we must undertake that simplification without scruples. It is to systems that we shall find our way, not to a particular subclass, ‘true systems’. Furthermore, we must (2) give up formulating examples as precisely as possible. Something that might require one hundred words to express precisely can often be expressed adequately in ten words. That is what Cassirer does in his presentation of Cusanus.

Other complications also arise. When we attempt precise formulations, we become dependent on a conceptual framework, a conceptual metasytem, that is then essential to describe the system at hand. As a result, certain difficulties will arise at an inconveniently early stage in our deliberations. Of particular importance is the difficulty associated with representing a system without presupposing another system as a frame, a wider system within which the former is presented. Although the metasytem might go beyond the system only at certain points, it, nevertheless, presupposes the possibility of seeing the system from the outside, a possibility that can hardly be present for the systematician himself.

It is disappointing to limit our presentation of examples to synoptic minima, but the two alternatives generate even less satisfactory examples. The first leads to examples that are unmanageably complex for our purposes (for example, A. H. Winsnes’s otherwise satisfactory presentation of Jacques Maritain’s philosophy). The second leads to meta-researchers who fail to give examples of whole systems (for example, Everett Hall).

Tore Nordenstam (1968b) has subjected what he calls “the deductive

ideal in ethics” to a criticism in principle.¹⁰ His study is relevant to our discussion because ethics *is* an essential part of total systems and because we shall focus our deliberations on the pyramidal simplifications of systems.

Nordenstam thinks that the deductive ideal is clearly formulated by Richard Brandt in the following words:

Ideally a normative “theory” consists of a set of *general* principles analogous to the axioms of a geometrical system. That is, ideally it comprises a set of *correct* or valid *general* principles, as *brief and simple* as possible compatibly with *completeness* in the sense that these principles, when conjoined with true nonethical statements, would logically imply every ethical statement that is correct or valid. Such an ideal for a system must be our guide. (Brandt 1959: 295)

Nordenstam’s criticism seems completely justified, and it is good that Brandt in his valuable works has not let himself be led by the ideal he has set up!

Nordenstam suggests (1968b: 30) that Johan Galtung and I (1955) either had such an ideal for ethical systems or held that an ideal form of ethics must be deductive. This assertion does not hold water. In our opinion, it is a valuable undertaking to construct models for ethics or ethical systems, but this is not the goal of *descriptive* ethics. Models must necessarily be simple insofar as they are construed as descriptions. Nordenstam refers to a reconstruction of Gandhi’s political ethics in which it is explicitly stated that we are considering a model, not a description. In terms of the model, “derivations” are performed. By precization, these derivations acquire the character of deductions. In authentic systems, derivations are performed, but these can hardly be considered “deductions.” Deduction cannot be an adequate paradigm for derivation within a system. Furthermore, one must distinguish between an ethical system and ethically relevant behavior, both verbal and nonverbal.

Nordenstam correctly emphasizes the “openness” of ethics: “A satisfactory ethical system e.g. must be flexible enough to be amenable to application in new and unforeseen kinds of situations, and in order to be flexible the system must to some extent be open” (1968b: 30). Mathematical terms, on the other hand, have no flexibility (as parts of axiomatic systems). This distinction is well established. When Spinoza defines and derives deductively, this process occurs with concepts such as ‘definition’, ‘proof’, and

‘derivation’, which are *not* drawn from mathematics. To make reasonable sense of the statement quoted from Brandt, one must presume that he employs classical philosophical terminology. Even if Nordenstam’s criticism scarcely hits as hard as he intends, it is nevertheless commendable to emphasize that one is led astray by thinking that concrete ethical decisions can be deducible from more or less general ethical norms and descriptions of situations. This ideal cannot be presumed in ethics any more than it can be presumed in jurisprudence.

Thus, descriptive ethical research cannot be a search for basic ethical norms from which the rest of an ethics can be derived.

The open structure of ethics plays a role that has important methodological consequences for descriptive as well as normative ethics. Search for fundamental norms can no longer be regarded as the principal task of the descriptive analyst; his task will be to describe the whole system of moral norms, general and special, for the general norms cannot be fully understood in isolation from the special features which contribute to fixing their meanings.

(Nordenstam 1968b: 34)

This is quite clear as far as the ethics of nonviolence is concerned. A long series of more or less special norms is required to begin outlining what nonviolence involves. It is of no use to combine all ethically relevant concerns into a single basic norm “Be nonviolent!” One must proceed from rather special norms to particular individual decisions.

Knowledge of general principles in a person’s ethics does not render it superfluous to gather knowledge of his special moral decisions, just as acquaintance with the statutes of the lawbooks does not remove the need to study particular cases. Casuistry is an essential part of ethics.

(Ibid., p. 34)

Synoptic Philosophical Systems

Statement Sets That Satisfy Minimal Requirements for a System

What we, at least for the present, are searching for may be specified as follows: sets of brief, vague and ambiguous, true or false, but not completely unintelligible or vapid formulations that can act to demarcate

roughly and provisionally the basic features of a selection of systems. Such presentations cannot afford to be elaborate. We seek something that will just barely qualify as a representation of a whole system. The expression *synoptic systems* is perhaps good enough if one keeps in mind that while requirements of precision are minimal, requirements of explicitness are not.

To be philosophically all-embracing a philosophical system needs to express a position on each of the five main topics of philosophy as they are usually represented. In general, to be all-embracing, a system must: say something general and fundamental about what is (ontology), say something general about knowledge (epistemology), say something about conditions for cognitive meaningfulness (semantics), have a consistent logic, and outline an ethics. Sometimes we can manage with less, but it is not an insuperable task to get at least one formulation from each of the five fields.

Everett Hall (1960: 3) contends that the categories of systems tend toward a triadic pattern corresponding to the classification schema of the philosophical disciplines: ontology (“investigating being”), epistemology (“studying knowledge or, more broadly, any reference”), and axiology (“concerned with values”). He therefore thinks that in order to ascertain differences in the categories of systems, one ought to search for principal concepts that are used or that are presupposed when there is discussion of existence, reference, and value. Hall’s schema may, at times, provide a fruitful basis for comparison, but it will quite likely prove to be unmanageable when a philosophy’s ontology is axiological (Heinrich Rickert?) or its axiology is ontological (Spinoza?). Similarly, it is difficult to reduce logic to ontology, epistemology, or axiology.

With regard to logic as a main topic in systems, a controversial question among foundation researchers in logic is the extent to which different formal logics may exist or be constructed. W. V. O. Quine (1953), however, claims to find an example of very different formal logics or logical ontologies in connection with the extensional/intensional distinction:

Intensional and extensional ontologies are like oil and water. Admission of attributes and propositions, along with free use of quantification and other basic idioms, rules out individuals and classes. Both sorts of entities can be accommodated in the same logic only with the help of restrictions, such as Church’s, which serve to keep them from mixing; and this is very nearly a matter of two separate logics with a universe for each. (Quine 1953: 157)

The conceptual framework of a system determines which questions can and cannot be considered, but can the metasystematician know this in advance? In the last chapter of this book, I address problems of this kind; for now I shall only add a brief comment.

The following question posed by Thomas Aquinas could also arise and be posed within other Christian medieval systems, but it could hardly be posed in any modern non-Christian system: will human beings need food after the resurrection? Great difficulties arise in connection with the introduction of 'resurrection'. If they are not addressed, the question cannot even be posed. W. M. Kneale and Martha Kneale condense Thomas Aquinas's argument as follows:

[I]t would be a denial of the good ordering of God to suppose that eating will take place after the resurrection. For a man who eats without losing anything by corruption will grow to an immoderate size (*perveniet ad immoderatam quantitatem*). Indeed, if after the resurrection a man continues to eat through the whole of his unending life, we must suppose that he will grow to infinity (*oportet dicere quod corpus hominis resurgentis in infinitum augeatur*). But that, he says, is impossible. (Kneale 1962: 647)

Since Aquinas's reasoning is remote for most of us, it is comparatively easy to list presuppositions or assumptions that must be taken for granted in order for the question to arise. Here it will suffice to mention two: (1) human beings are in a certain sense resurrected after death, and (2) human beings have a body after death. Only when these presuppositions are accepted can we attempt to put forward and assess a solution. In contrast, when we are very intimate with a particular way of thinking, it is often more difficult to identify such presuppositions and assumptions. In such cases, the system appears to stand on its own two feet, accessible and comprehensible to all.

The intended totality of a total system must not be exaggerated. In the first place, philosophical systems cannot describe everything; they should recognize their inherent incompleteness. It is the "types" of things, the objectual, that systems aim at, rather than particular individual things. Even in the case of types, it is clear that not all of them are intended to be separately characterized or characterizable.

A reflection of Jaspers's and many others is worth mentioning in this connection:

A simple logical consideration shows us that nevertheless the whole and the absolute *cannot be object* for us, because as subject we would then have to stand opposite those as an object, while we as subject are then not included in the object, hence the whole is then not the whole. (Jaspers 1919: 161)

When a philosopher at a certain time or by an act of thought seeks to contemplate his total system and thereby also reconsider what the statements of the system are about (refer to, designate, denote), he cannot actually perceive the act of thinking. The dated, concrete act of thought is part of a process. His next “act of thinking” may turn the preceding one “reflectively” into an object. He objectifies what went on. If he thinks that what went on was worthy of particular philosophical attention, his system will include a characterization or theory of such acts of thought. By “such,” we mean a kind of thought, not a singular event. The system is “open” in the sense that new acts will fit in; they do not rupture the frame. The whole is not “the whole” in a certain absolute sense, but rather how one might reflect the intention of a thinker that aimed to encompass everything singular.

One is reminded of the myth that Hegel refers to about the embittered god who creates but thereafter swallows the world. In clear moments, great system builders have hardly conceived of the system idea as crudely as this. They do not seek to halt the course of events simply to prevent something, to which they did not already lay claim to, from happening. Hence, Jaspers’s misgiving does not seem to apply to *philosophical* systems in which totality is viewed as intention.

Full Explicitness Is Required of Synoptic Systems

In a certain respect, our synoptic systems are not at all minimal. We make more than minimal demands with regard to our requirements for explicitness. This is a consequence of, inter alia, the goal of establishing maximal comparability between synoptic systems. Furthermore, we require that the text be intelligible and valid without reference to biographical material, such as statements about the author’s emotional life. Pessimism in principle is not verified by reference to an author’s remarks about being terribly pessimistic and depressed. A doctrine of anxiety as a basic human attitude in principle is not verified by the author’s anxiety at one moment and then falsified by his lack of anxiety at a later moment. Systems are consid-

ered to be “detached” from the personality of the system builder. The builder may have some special basic attitudes, but they must be verbally expressed with a claim of intersubjective validity in order to be accepted as examples. Statements such as “The spiritual is higher than the corporeal” and “Any evaluation is subjective” may be accepted, but not “To *me*, the spiritual seems higher than the corporeal.”

The more deep-seated a standpoint, the more difficult it becomes to maintain its separability from the personality said to take on this standpoint. Emmanuel Mounier’s personalism reflects his way of experiencing and associating with his fellow human beings. Personalism as a system standpoint, however, is nonpersonal. Its truth conditions do not refer to the person Mounier. As soon as the detachability requirement is rescinded, however, the system loses its intersubjective, cognitive character. The task of comparison then disappears as a *philosophical* task, falling instead to biographers, psychologists, sociologists, biologists, and physicians. The nonpersonal character of the systems does not mean that the study of systems can be undertaken without any study of persons; quite the contrary. The person who wants to understand and compare must, as directly as possible, expose himself to different personalities and identify himself with their life situations. (In Indian philosophical tradition, the direct personal confrontation appears, in principle, to be presupposed. A verbalization — or an eloquent silence — must be interpreted in terms of the total teacher-disciple relationship.)

A person may change his mind about female ministers, pacifism, and much else, but can he change ways of understanding, total views, and conceptions of himself and the outside world? The question is open. Some will, from certain premises, answer yes; others, no. It seems clear to me, however, that one cannot “have a (nearly total) system” or “have a total view” the way one can “have an opinion.” One ‘is’ more than one ‘has’, in the case of deep-seated attitudes. We agree, presumably, that one person cannot be several persons, but can one person compare several systems? Which more profound ways of understanding can this person have? The question is a burning one if, like Guttorm Fløystad (1967: 2), one has the working hypothesis “that a person’s identity is closely connected with a person’s understanding, that a person in an essential sense is or is constituted by his understanding.”

When we say that Spinoza’s, Leibniz’s, and Kant’s philosophies give expression to three different personalities’ total views of existence, it is not a semantic relation that is intended but a psychological or existential one.

The system may be more or less apt and may be a more or less pedagogically and didactically adequate expression of a fundamental view or vision. Dilthey and his school sought to understand systems in terms of noncognitive expressive relations. Carnap emphasized them and declared the cognitive claims to be misapplied: the metaphysicians are bad musicians, meaning that they would have, had they been more musically gifted, expressed themselves in music. In this work, however, we take seriously the system builders' cognitive, interpersonal claims to validity. We have no grounds, in principle, for rejecting those claims. We must also acknowledge that a fundamental view or a basic vision can in principle be given expression by different cultural products — poems, philosophical systems, music, drama, and sculpture. Indeed, some individuals are creative in the worlds of several media (Nietzsche, for example).

Three Examples of Synoptic Total Systems

Formulation Set F1

1. Everything that exists can be experienced.
2. The ultimate source of all knowledge is experience.
3. Two statements that directly contradict each other cannot both be true.
4. All cognitively meaningful statements are statements about something that can be experienced.
5. Choose the strategy of action that gives the greatest possible happiness to the greatest possible number.

The first two sentences, ontological and epistemological, are meant to exemplify possible sentences in an “empirical” system. The third sentence, which exemplifies a logic, is merely a formulation of the principle of contradiction. The fourth sentence provides an empirical criterion of meaning (of the form that is associated with logical empiricism). The fifth sentence, a formulation of the highest norm for deciding actions, introduces a utilitarian ethics.

The catchword *empiricism* fits the formulation set F1. The following set, F2, is intended to exemplify “materialistic” systems. The list is not intended to fulfill the minimal requirements in every detail.

DESCRIPTIONS OF MAXIMALLY COMPREHENSIVE PERSPECTIVES

Formulation Set F2

1. Of nothing, nothing becomes.
2. Everything that exists is corporeal.
3. Of the bodies, some are composites of bodies; the rest are that which all the other composites result from. These, the “atoms,” are indivisible and unchangeable.
4. Atoms have no properties apart from size, shape, and weight.
5. The soul is a body that is distributed in the whole human body.
6. The human body covers the soul and leads sensations to it.
7. Any pleasure is a good thing; any pain is an evil.
8. Spiritual pleasure is better than bodily pleasure.
9. The virtues can be reduced to wisdom.
10. Wisdom teaches that enduring pleasure can be obtained only by nobleness and justice.
11. The basis of all cognition is sense experience.
12. Sense experience is true in itself.
13. The immediate objects of cognition are sense pictures, not things in themselves.
14. Criterion of truth: confirmation through sense experience.
15. Two statements that directly contradict each other cannot both be true.
16. All cognitively meaningful statements are statements about something that can be experienced.

The set F2 is a freely condensed rendering of Friedrich Lange's (1866) classical representation of Epicurus's system. The first four sentences may, roughly classified, be said to provide an ontology; sentences 5 and 6 outline a philosophical psychology; 7 through 10 outline an ethics and art of living; and 11 through 14 represent an epistemology. Logic and semantics (sentences 15 and 16) have been added by borrowing from the formulation set F1.

F2 is not an entirely satisfactory example of a minimal system because some of the sentences can hardly be construed as fundamental, for example, numbers 8 and 9.

Formulation Set F3

1. Dialectics

- 1.1. That which exists, nature, is a continuous, uniform whole, where things are organically interconnected.
- 1.2. Nature is in a state of incessant movement and change.
- 1.3. Qualitative changes do not occur by degrees, but quickly and suddenly; not accidentally, but according to law.

2. Materialism

- 2.1. Nature is material; the varied phenomena are different forms of matter in motion.
- 2.2. Matter has objective reality outside the human consciousness and independent from it.
- 2.3. Our knowledge of the laws of nature is reliable, and there are no unknowable things.
- 2.4. Things in nature have internal oppositions.

3. Addendum

- 3.1. Matter can move only in space and time. Thought is a product of matter, specifically the brain. A thought without a brain is absurd.
- 3.2. The function of consciousness is to give reflections (“copies”) of that which exists (including the regularities).
- 3.3. There is no god or world spirit or idea; the material, observable world is the only one that exists.

Parts 1 and 2 provide a simplified version of a summary of dialectical materialism given by Joseph Stalin (1940). Stalin provides examples of “internal oppositions” (also, in Hegelian fashion, called “internal contradictions”); thus, opposites are “+ and –, differential and integral, action and reaction.” I have added part 3 myself to provide a more comprehensive picture.

Simple Comparisons: Conflicting Systems and Criteria of Totality

The comparison of systems may be relatively unproblematic. This is the case with F2 and F3. Nevertheless, the comparison of F2 (“Epicurus’s system”) with F3 (“dialectical materialism”) presupposes, *inter alia*, elucidation of three key issues:

1. How are ‘nature’, ‘world’, ‘matter’, and ‘mind’ related within dialectical materialism? If matter is outside consciousness, then consciousness is outside matter, and thus consciousness is not material. Is consciousness without material being? What is the ontological status of consciousness?
2. What is the relation between *everything* as the word is used in sentence 2 in Epicurus’s system (“Everything that exists is corporeal”) and *world* in the addendum to F3?
3. What is the ontological status of “sensations” and “sense pictures” in Epicurus’s system? What is their relation to “corporeality,” to “the soul,” and to the “consciousness” of dialectical materialism?

F2 and F3 are related systems insofar as they take up the same questions in the same, or closely related, terminology. The solutions are similar. The systems can, to a great extent, be compared and discussed in a common terminology. Especially important is the absence of differences in logic and (explicit) methodology. Even a very small difference in basic methodological norms can render comparison impossible.

It is easy to see that the formulations of systematizers after Aristotle are to some degree determined in terms of supposed (hypothetical) contrasts to the formulations of other systematizers. They no longer start from scratch but find their bearings in relation to a rich philosophical tradition. In the case of Thales and other very early thinkers in occidental philosophy, it is also evident that they contrast themselves to earlier or contemporary personalities and opinions, but the picture they present is not as well clarified philosophically.

We now need an example of a system that is formulated in direct opposition to another one. We select a “rationalistic” system contravening the “empirical” system F1.

Formulation Set F4

1. Everything that exists falls into two classes: that which can be experienced and that which cannot be experienced.
2. The ultimate source of all knowledge is rational thought.
3. Two statements that directly contradict each other cannot both be true.
4. Any noncontradictory statement has cognitive meaning.
5. Truth is found in the last instance by logical analysis; the thoughts must be made clear and distinct.
6. The good and right way of living is the one that obeys the law of reason.

To begin with, we accept that F1 and F4 express different doctrines, and that the differences, at least in some points, are such that F1 and F4 cannot both be asserted together without contradiction. Therefore, we accept the assumption that F1 and F4 are incompatible. Our assumption may be explicated by listing the vocabularies in F1 and F4 and postulating that the same words have the same meanings, hence that *experience* in F1 means the same as *experience* in F4, *knowledge* in F1 means the same as *knowledge* in F4, and so on. Such an approach presupposes a large set of intersubjective synonymy hypotheses. Substantial difficulties arise when one attempts to verify each synonymy hypothesis.

In such a comparison of F1 and F4 we will also require a definition and criterion for incompatibility, that is, a logic that includes a principle of contradiction. What is suggested of logic in F1 and F4—the principle of contradiction—is common to both systems. However, F1 and F4 have incompatible methodologies: the comparer's conclusion that "F1 and F4 have incompatible methodologies" is intelligible and testable only in terms of a particular logic and methodology. The question immediately arises as to whether this logic and methodology of comparison is neutral in relation to the logic and methodology of F1 and F4. Here we begin to approach the special difficulties that must arise if methodologically incompatible systems are intended to be complete.

If two systems have incompatible methodologies, the partial or total system that is to serve as a frame of reference for a comparison will have to have a methodology that is compatible with either one or the other. By

adopting one alternative as a metasytem at the expense of the other, one takes a stand against the latter even before any comparison has begun. In making such choices, the system comparer cannot be totally “unbiased.”

More generally, if two systems are incomplete, the differences between them may be such that a metasytem does not have to side with one or the other, because the two systems may be entirely compatible from a logical point of view. In the case of two total systems, however, the situation is different. In this case, both systems must say something, implicitly or explicitly, about every subject that is taken up. The existence of a logical incompatibility implies that the metasytem takes a stance on one side or the other. *Tertium non datur*—there is no third option. If one system asserts *A* and the other not-*A*, it is of no avail to search for a synthesis or a neutral position. If it is asserted that the first system covers one aspect of existence and the second another, then both have failed to satisfy the pretensions of total systems, because each system was intended to cover everything.

What do we mean by saying that a system is or is not complete and total or that it expresses a total view? We shall try to identify some criteria by beginning quite vaguely:

1. A system is total if (but not only if) it comprises an ontology, epistemology, logic, semantics, philosophy of language, methodology, value theory, ethics, moral philosophy, philosophy of law, philosophy of education, political philosophy, philosophy of history, history of philosophy, and philosophy of nature.
2. A system is total if it comprises all categories.
3. A system is total if in principle no statement is irrelevant in relation to the propositions of the system.

One way of characterizing total systems is to say that if *x* is intended to be total, then nothing can be irrelevant for its validity and nothing can fall outside its categories. Stephen C. Pepper calls such systems “world hypotheses.”

Among the variety of objects which we find in the world are hypotheses about the world itself. For the most part these are contained in books such as Plato’s *Republic*, Aristotle’s *Metaphysics*, Lucretius’ *On the Nature of Things*, Descartes’s *Meditations*, Spinoza’s *Ethics*, Hume’s *Treatise*, Kant’s three *Critiques*, Dewey’s *Experience and Nature*, Whitehead’s *Process and Reality*. . . . These un-

restricted products of knowledge I am calling world hypotheses, and the peculiarity of world hypotheses is that they cannot reject anything as irrelevant.
(Pepper 1942: 1)

In practice, and at least to begin with, criterion 1 is the best of the three, but then, of course, its formulation must be made more precise. One must also determine what may be subtracted from the suggested philosophical disciplines without infringing on the totality of a system. An important point is that one must avoid inserting whole encyclopedias into the total systems. There can be no place for science or technology. The relation expression “*x* comprises *y*” must be made precise, perhaps in the direction of “*x* has the explicit or implicit consequence *y*.” Another quite different sense is also of interest, “*x* has *y* as a (genuine) part.”

Finally, for the sake of comparison, we offer condensed presentations of the more traditional type that highlight the main ideas in Hegel’s and Schopenhauer’s systems. The presentations demonstrate a tendency to use terms that are clarified only within the systems (esoteric elucidation). From the metasytematic point of view, this is the great weakness of the more traditional presentations; they do not lead into systems but rather presuppose that we are already inside them. If one uses ordinary interpretations of words in reading such a presentation, it often becomes meaningless or erroneous.

Hegel’s System: Traditional Condensation

1. Appearances for us¹¹ are not only in our consciousness, but also in themselves.
2. The source of their being is the general divine idea (*die allgemeine göttliche Idee*).
3. Absolute reason reveals itself in nature and spirit, and is the substance of both.
4. Consideration of the realization of absolute reason in the development of history forms the dialectical method, which reproduces in the consciousness of the thinking being the self-movement of the content thought.
5. Absolute reason externalizes itself in nature and returns from its difference to itself in spirit (*enttäusert sich und kehrt ihrem Anderssein zurück*).

DESCRIPTIONS OF MAXIMALLY COMPREHENSIVE PERSPECTIVES

6. The realization of absolute reason is threefold: in the abstract elements of thought, in nature, and in spirit; as thesis, antithesis, and synthesis.
7. Freedom is the idea that has returned from its difference to itself, the spirit.

This condensed version of Hegel's system can only be of value to those who are already acquainted with a series of difficult terms that admit a variety of interpretations.

*Schopenhauer's System: Traditional Condensation*¹²

1. The only reality that is independent of our ideas is the will.
2. The will is not an object, but an urge and a desire to be.
3. Any object is merely some subject's idea, only phenomenon.
4. An urge cannot be fully satisfied, hence the presence of suffering.
5. The highest norm for a conscious being is to kill the urge.
6. Compassion alleviates suffering, asceticism kills the urge.
7. Nirvana is the happiest, final stage of asceticism.

If we proceed on the assumption that Hegel and Schopenhauer intend to create total systems, the first great task will be to distill out the common topics. The first sentence in the Hegel condensation says something about appearances for us (*Erscheinungen für uns*). What does Schopenhauer have to say about the subject that Hegel intends by the expression *Erscheinungen für uns*? In the third sentence of the Schopenhauer condensation, the word *phenomenon* occurs. There is reason to believe that by *phenomenon* Schopenhauer means something not far from Hegel's *Erscheinung für uns*. By successive reformulation it is possible (yet not without a certain arbitrariness) to establish that the two systems among other things have a common topic, the phenomena, and that they also contain some incompatible statements about this topic. From the Hegel condensation we deduce: any phenomenon is not only in our consciousness, but also in itself. From the Schopenhauer condensation we deduce, after "translation" to Hegelian terminology: for one phenomenon it is the case that it is not only in consciousness, but also in itself, namely the will.

In an analogous way, the metasytematizer will seek to delimit other common topics. It will soon become evident, however, that there are topics that only one of the philosophers appears to have taken up in his writings. In such cases, we must resort to extrapolation. Even after daring extrapolation, we must still expect the persistence of many topics on which only one of the philosophers can be said to have expressed his view directly or indirectly. This lopsidedness, however, cannot be taken as evidence that the systems are not total in their intention.

Standpoint Combinations: Extrapolation

According to the judgment of posterity, only a few philosophers have produced truly outstanding work in all the principal areas of human, system-creating thought. Others have made outstanding contributions in more restricted areas: Descartes in epistemology and the theory of science, but not in ethics; Nietzsche in ethics and the theory of values, but not in ontology; Frege in logic and semantics, but hardly in any other field. These facts make it necessary, in order to obtain a culturally rich and interesting set of systems, to proceed tentatively when combining doctrines that have less scope or depth into total systems.

From the perspective of psychology, sociology, and the history of ideas, syntheses constructed by combining doctrines from different thinkers, such as Aristotle and Frege, may be regarded as completely “impossible.” Anthropologists might deny that any thinker could arrive at such syntheses and at the same time believe in them. From a systematic-cognitive standpoint, however, these “artificial” combinations may be of great value because they exercise our logical imagination and undermine our tendency to believe that the range of cognitively possible standpoint combinations is limited to the few truly comprehensive systems that occur in history.

Let us, for example, focus on the writings of philosophers who are most broadly reviewed in textbooks on the history of philosophy. If we make a list of one hundred questions that two or more of these philosophers have answered, it turns out that certain answers in their systems hang together. For example, answer R₁ to question Q₁ is more frequently combined with R₅ to Q₂ than with R₆ to Q₂. In other words, there exist positive and nega-

tive correlations between the answers when they are classified according to similarity and dissimilarity.

Since we do not, in general, find that different philosophers give exactly identical answers to any definite question, we must make an effort to classify answers that fall into categories such as “very nearly the same answer,” “not very nearly the same answer,” “answers that are very nearly the negation of another one,” “answers that neither very nearly negate nor very nearly affirm a certain other answer,” and so on. When we say, for example, that Pierre Gassendi, Thomas Hobbes, and Julian Offray de La Mettrie are materialists, we have tacitly understood that they give nearly the same answers to nearly identical questions. If, however, we add that Gilbert Ryle and Ludwig Wittgenstein are also materialists, either our requirements for similar answers (and the feasible questions) are considerably weaker, or we must reformulate the questions relevant to “materialism” so that they are more abstract or incomplete.

Most philosophical topics are so intricate and the methods of justification so imperfect that the assumption of “cognitive affinity” should be regarded as no more than a working hypothesis. By “cognitive affinity” I refer to a relation between *A* and *C* such that if *A* is tenable, then probably *C* is also; or if *A* is untenable, then *C* is also probably untenable. (If both relations hold, it is perhaps appropriate to speak of “mutual cognitive affinity.” The relationship is formal-logical if, for example, *C* follows from *A* in a formal-logical sense.)

Attempts to check answers for cognitive affinity will most frequently result in a weakening of the hypothesis or in a realization that it is untestable, at least with the methods currently at our disposal. The conclusion will often be that the hypothesis about cognitive affinity is useless except as a working program. This usually gives us more prejudices than fresh insights, and it applies perhaps to the majority of hypotheses that seem to be accepted implicitly by the authors of histories of philosophy. A series of clever special investigations in the history of philosophy concludes that opinion *C*, which has commonly been supposed to be accepted by philosopher *F*, is not *F*’s opinion. He has, on the contrary, meant *D*. The assumption that he meant *C* has been determined, for example, by the fact that he has the opinion *A* (and not *B*) about another topic, and one frequently assumes that *C* follows from *A*.

For example, one of Paul Natorp's main theses in his *Die Ethika des Demokritos* (1893) is that Democritus does not mean that pleasure is the goal (*télos*). While it is the case, he writes, that Democritus holds that pleasure and displeasure are the criteria (*tá kritéria*), it does not follow from this that pleasure becomes the goal. Natorp denies that Democritus sets pleasure as the unconditional goal, a position long since accepted by many historians of philosophy; but he shows, by distinguishing criterion from goal, that he can nevertheless make sense of Democritus's doctrine. Furthermore, Democritus, in his ontology, is a consistent materialist and a determinist (in a certain sense). Does he not, therefore, believe that both positive feelings and beneficial material things are most worthy of being coveted?

On the basis of standpoints for which there is no evidence in Democritus, but by association with certain other philosophers who may also be said to be consistent materialists and determinists, one might answer yes. In the sentences preserved from Democritus, however, the philosopher does not emphasize the material, but rather the mental benefits (*tá psychés agathá*). Is he not inconsistent then? Are the fragments spurious? Natorp thinks Democritus need not be inconsistent. Democritus's theory of values emphasizes psychic values, and since his theory of atoms does not exclude the condition that psychic atoms are important causally for one's happiness, the ontology does not prevent him from thinking so.

Natorp continues, and finds a very close connection between Democritus's epistemology and his doctrine that the soul's state of calm is more important than isolated sensations of pleasure. Pleasure and displeasure are ontologically on a par with color and taste; hence they exist only in people's speech and opinion (*nómo*), not in reality. Natorp finds a cognitive affinity, and perhaps even something close to a formal-logical, necessary connection, between Democritus's epistemology and his ethical doctrine. Here, however, Natorp seems to be skating on thin ice. He may be explicating a possibility that stands historically with other possibilities, but if these possibilities are compared with each other, the conclusion would have to be one of *isosthenia* (a state of suspended judgment). The alternatives are equally probable or improbable; there are equally strong reasons pro and contra.

It may well be that from a psychological, sociological, culture-historical, or idea-historical point of view it is unreasonable to imagine an answer of the kind *A* to question *x* combined with an answer of the kind *D* to

question *y*. Precisely because psychological and other kinds of knowledge about man are essential for understanding the opinions of philosophers, we can argue that the maximal variation of psychological and other factors will result in many more combinations of opinions than have so far been represented. One may point to a wide variety of psychological, or at least generally culture-historical (for example, science-historical), factors that have been common to many and perhaps all of the philosophers most frequently cited in history of philosophy textbooks. From a cognitive standpoint, such factors are fortuitous; they do not affect the tenability of arguments or their weight as evidence.

We conclude, therefore, that if one is predominantly interested in the elucidation of standpoints—exactly *what* the individual philosophers meant, rather than *why* they meant it (what motives they had)—then one must critically scrutinize all inferences of the following kind: since he means *A*, which he explicitly states, then he means *C*, which he does not explicitly state. Many of these inferences will turn out to be untenable.

Furthermore, if one is predominantly interested in the internal relations and relative tenability of possible philosophical positions (here equal to noncontradictory positions), it is desirable in principle to consider all and-connections that may exist between the various theses of the philosophers and then examine and evaluate the non-occurrent combinations (including negations). Hence, if *A*, *C*, and *E* occur combined in history, as do *B*, *D*, and *F*, then we should consider the combinations (*A*&*B*, *A*&*C*, . . . , *A*&*F*; *B*&*C*, *B*&*D*, . . . , *E*&*F*; *A*&*B*&*C*, *A*&*B*&*D*, . . . , *D*&*E*&*F*, . . . , *A*&*B*&*C*&*D*&*E*&*F*) and also the negations (*A*&-*B*, -*A*&*B*, -*A*&-*B*; *A*&-*C*, -*A*&*C*, -*A*&-*C*, and so on).

On the whole, however, system-philosophical combinatorics is poorly developed. Interest has presumably been focused until now on views proclaimed by great personalities; but the intellectual pleasure of peeking into worlds with great internal order and harmony is not diminished just because no one has yet believed in their existence.

How can systems vary demonstrably with respect to concepts such as 'meaningful', 'analytic', and 'a priori'? One way to understand this is to take these concepts as points of departure; then their occurrences (and traditional translations and equivalents) are compared. A survey of precizations is developed as one clarifies, step-by-step, differences in usage. For these differences in usage one then postulates conceptual differences, inasmuch as one

assumes that conceptual characteristics vary in parallel with the differences in usage. Some such differences were clarified by Nordenstam (1972).

The precondition is to have a sufficiently broad common reference frame so that occurrence analysis and precization analysis can be given a common description. Furthermore, the words employed in the formulations of conceptual characteristics must also be shared. Closely considered, this turns out to be a radical requirement, because the less two systems have in common, the more difficult it becomes to map uses and conceptual differences in a tolerably neutral and complete way.

One difficulty in principle arises because the level of depth of intention (and the level of discrimination) cannot be assumed to be infinitely high. The history of the words used in classical logic and modern debate makes it probable that strong precizations become more or less transintentional. Hence, one gets constructed system differences rather than purely descriptive ones. Regarding the limits of precization, Anders Wedberg's (1958–66) offers helpful points of departure for a thorough study. He characterizes 'meaningful', 'analytic', and 'a priori' as "exceedingly problematic distinctions" (1958–66, vol. 3: 247). It is doubtful if any consistent transintentional precizations are sufficiently close to the original, vague uses regarded as plausible, even with very modest requirements for "plausibility."

The limits of precization inhibit system variability. If we view these precizations as branches of the philosophical family tree, they become small and stunted. Why? Perhaps because the imagination of researchers is hampered by the thought that only one concept can be the correct one and that it is to be found in the vicinity of concepts that have already been suggested in the philosophical literature.

Philosophical combinatorics is poorly developed because many imagine that truth is approached from only one direction, or, alternatively, that one searches for truth along certain lines and is impatient with others. Combinatorics presupposes a kind of *epoché* (withholding of assent or dissent in matters in which conflicting and equally plausible explanations exist) in relation to all attempts at solutions.

Introduction to Systems and System Comparison

Historiography of philosophical systems as total views involves problems of theoretical kinds that are rarely discussed. An attempt is often made to

introduce a system, for instance, writing a chapter on it and comparing it with a couple of others. It is sometimes uncritically assumed that the historiographer can start as a neutral being without presuppositions of relevance to the system he is going to introduce. This is scarcely possible because a philosophy of history is part of the system, dependent on epistemological and methodological views. Perhaps we must acknowledge that the introducer implicitly depends on his own system.

An introduction to a system may be conceived as leading from one system to another or from systemlessness to a system. In either case the introduction begins in territory foreign to the system being introduced. If the reader is already familiar with the system, no cognitive introduction is required. Instead, the introduction may take the form of a pedagogical arrangement or a condensed, explicit representation. In this section, however, our reader is presumed to be, cognitively speaking, an outsider, one who has no prior acquaintance with the system.

Presenting a system may seem easy as long as one does not perceive one's presentation as number ($n + 1$) in the series. A researcher, however, cannot ignore previous attempts at presentation, and a study of these prior presentations will illustrate how different persons, generations, traditions, and movements have presented contrasting pictures of one and the same philosopher. The primary aim of the current system introducer, then, is to give a presentation that does not attribute to his predecessors thoughts that are alien or foreign to their philosophy—at least not in such a way that their own intentions become obviously distorted.

Nonetheless, a researcher who is fully aware of these traps *in abstracto* may still fall into them when it comes time for concrete formulation of a representation. Our main concern now will be to examine one more or less direct interpretation. The example concerns the Spinoza researcher Harold Foster Hallett, who begins the preface to his *Benedict de Spinoza: The Elements of His Philosophy* with some weighty sentences of which I shall quote the first two:

Probably no philosopher of repute has been worse served by his expositors and commentators than Spinoza. Monist, pantheist, atheist, acosmist, ethical nihilist, mechanist, mystic, and even dialectical materialist, are among the epithets more or less commonly used to describe and pigeon-hole a doctrine which, nevertheless, though neglected, misinterpreted, and deplored, has never been despised as a mere curiosity of philosophical history. (Hallett 1957: vii)

The modern Spinoza researcher faces a difficult task:

[I]t is not easy for the modern mind, steeped as it is in empiricistic modes of thought subsequently developed, to take up the intellectual standpoint from which alone the thought of Spinoza is intelligible. Yet, of course, until this has been accomplished, exposition and criticism alike are futile.

(Ibid., p. vii)

Hallett is, of course, correct in demanding that one not apply current natural science conceptions of causal connections to Spinoza's texts. The texts must be understood as much as possible in the context of the traditions that were a part of Spinoza's life, traditions that were dramatically different from "ours" today. Is this possible?

As I see it, it is impossible in practice for us today to see the world as Spinoza did and to find out exactly what he meant by his words, and to express this in the vocabularies of our time. Those who try very seriously through years of intense study arrive at differences of great interest. Exactly what did Spinoza mean by the term *causa* in the *Ethics*? What is the relation of the meaning of *causa* to the meaning of *ratio*?

When the goal is to search for more authentic interpretations of Spinoza, however, Harry Wolfson's comprehensive idea-historical *Philosophy of Spinoza* (1934) almost always proves helpful. Wolfson approaches Spinoza's concepts "cause of itself" and "essence that involves existence" through a study of Descartes, Anselm, Crescas, Avicenna, Averroes, Maimonides, Porphyry, and of course Aristotle. His approach may sound daunting, but it turns out that this long detour to direct interpretation permits one to ascribe to Spinoza a couple of very simple, but nevertheless fundamental ideas.

In the first place, God must be such that he has no cause. If God were caused by something, the very existence of God would then depend upon this causing agent, and this agent could at any point take over God's role. God would then be subject to the discretion of another entity.

Between this first thought and the next, that God is his own cause, one may imagine a broad realm of possible interconnections. Wolfson's presentation, however, if it is adequate, permits one to assume that there are no such intermediate links at all. That God is the cause of himself needs for Spinoza to have been nothing but a manner of speaking, another way of expressing what is a relatively simple thought: that God himself cannot have any cause.

A third thought arises when we compare this idea of God's causality to the idea of the "accidental" existence of objects of experience. For example, although we can give an exact description of a thing's nature, this does not necessarily imply that the thing must actually exist. Things must be seen as links in chains of causes or conditions. We assume that for a thing to exist, certain conditions must be realized. We must see the thing as a link in a chain of causes or conditions. We can reformulate Spinoza's concept of God in a new way: God's existence is independent from such conditions that must be realized. Hence, God exists purely as a result of his own nature. In short, God's nature hinges on existence itself; the nature of things, however, does not even necessitate their existence. They may be conceived to exist just as well as they may be conceived not to exist.

Wolfson's contribution here is not so much that he actually puts forward such an interpretation, but that he demonstrates its plausibility through his comprehensive review of historical material.

Hallett's basic formula for the essence-existence relationship is introduced as follows:

Finally, the relations and distinction of essence and existence in 'God or Nature', i.e. of the infinite indeterminate primordial potency-in-act and its infinitely determinate enactment or actuality, serve to determine Spinoza's account of the divine causality as *free* and as *immanent*, and being both free and immanent, as *eternal*. With 'God or Nature' essence and existence are at once identical and distinct as the indeterminate is identical with and distinct from its exhaustive determinations—a complex relation which is generally expressed by Spinoza in the form: 'The essence of God *involves* existence'.

(Hallett 1957: 27)

Some of the expressions that Hallett uses here and elsewhere to bring the modern student to an elementary understanding of Spinoza are neither Spinoza's nor the modern student's. Hallett interposes a third system between the two. A third system in itself is entirely reasonable, but his mediating system fails didactically. This failure owes, for example, to the expressions "potency-in-act" and "identical and distinct." The basic concept 'action' is introduced by the phrase "by 'action' is meant the *actualization of potency*" (ibid., p. 5).

"Cause of itself" is mainly explained by the following third-system passage:

[S]ubstance actualizes and manifests itself in the mode—it is the active cause, and the mode its enacted effect. Self-actualizing and self-manifesting substance is thus essentially real and intelligible as ‘cause of itself’, i.e. as creating its own actuality, exhaustively and eternally. The primordial Real is substance as infinite indeterminate potency eternally actualized as exhaustively determinate mode, and is thus self-existent, self-manifest, *causa sui*.

(Ibid., p. 12)

Ordinarily, we do not notice interposed third systems, but Hallett’s is so forbiddingly expressed that we notice what happens, and take umbrage. Hallett states that his book “is devised as a monitory preparation for deeper study of the philosophy of Spinoza” (1957: viii). He does not, however, mention that he presupposes a third system.

I will not deny that this third system has potential for bringing the modern student closer to Spinoza, but the system needs to be introduced before it can bring such help. As far as I can detect, Hallett has not been sufficiently concerned about this issue. A final evaluation of his introduction to Spinoza, via this third system, must therefore be postponed until this introduction to the auxiliary system is at hand. Hence, we must employ a fourth system. Or does Hallett have in mind those modern students who are already familiar with Thomas Aquinas?

In the case of “cause of itself” and “essence that involves existence,” Wolfson provides a shortcut, since he succeeds in giving the expressions a sense, at least on the level of everyday understanding, that is relatively easy for the contemporary student to grasp. A third system is therefore not necessary because the expressions employed are not likely to be perceived as outlandish.

A philosophical author who works with his system his entire life, as Spinoza did, and who constantly makes changes, tends to write in the form of an introduction intended for himself. Indeed, such an author can never be entirely inside his system. The author feels that he is on his way into something, into something that he both dimly perceives and incompletely grasps. The system is created on the way; it is always more of an intended than an actualized entity, a regulative idea, something not yet existing—a fiction in Hans Vaihinger’s terminology (1911). It is not merely a question of giving something already existing a coherent, written form; the purpose is not merely autodidactic. Spinoza’s *Ethics* was, after all, gradually modi-

fied from an essentially introductory style with numerous appeals to the reader, to a form in which the system was more self-contained—a ship in which all gangways were cleared away.

In writings by systematicians, written partly in an introductory style, one must recognize that a terminology, a conceptual structure, and a set of propositions and rules are employed. Moreover, these formulations may only gradually be ascribed the senses they are to have in the system. Furthermore, in the course of the presentation, the formulations may be criticized and even eliminated. The reader must attribute an outsider's meanings to the introductory formulations. He is then led in the direction of the system, and step-by-step the meaning is altered.

In principle, it should be possible for the author to let nothing be affected by what is presupposed or used in the first chapters of the introduction. Only when the introduction is completed, when the reader has been led into the system, can he assess what had a merely didactic function and what was to become an essential element of the system.

In a dialogue between a representative of the system and an outsider, the same introductory process must take place. If the representative of the system remains both in the system and in the dialogue, the result can easily be an esoteric style in the derogatory sense: the listeners who are already in the system can nod approvingly, while the outsiders have to find their own way. This approach seems to be employed more frequently in the Dionysian-Pythagorean milieus than in the logically and empirically minded philosophical milieus. Such an approach excels when the representatives of the system (1) avoid statements that they must retract when a more advanced step is reached and (2) can permit themselves to regard everything from the point of view of the system, even questions from outsiders. When the system approaches being total, outsiders' attempts to enter the system will be interpreted in the light of the author's views of the system representatives, so much so that they cannot find any way to accommodate an "antagonist" by going beyond their own system.

The purpose of these remarks is, in part, to lay the groundwork for examining the philosophical literature that focuses on evaluating the border between didactics and systematics in the writings of individual authors. A question arises as to whether Hume's formulations might have a purely didactic component. For example, Cassirer criticizes or comments on Hume's doctrine of the impermanence of the "I" by saying that Hume, in his own

formulations, appears to accept its permanence (by virtue of acting as the author of each sentence?). Might such a didactic element be precisely what Cassirer bases his criticism on?

Hume compares the mind to a scene in which perceptions appear and disappear without any other “I” than the scene. But how can Hume himself reflect on his perceptions?

How can the I in the form of pure “stage” for the perceptions, at the same time step out of its passivity and autonomously intervene in the play of the perceptions? How can we instead of merely receiving the content “reflect” on it and thereby put a new stamp on it? (Cassirer 1906–07, vol. 2: 386)

Hume’s response might be that Cassirer’s description of the “I” is not adequate. Hume’s way of writing gives an introduction. The picture employed, that of the stage on which perceptions appear, is didactically determined. As to Hume’s text about perceptions, this picture changes nothing about those perceptions.

How Hume would contrive to achieve a consistent answer, I dare not surmise. The essential point is that when Hume speaks about perceptions, and when he says that he has never come across any “I” outside the succession of perceptions, one cannot immediately conclude that there is an inconsistency. One should first consider whether Hume’s statements might be given an interpretation within the system or be defined as didactic statements, signposts for traveling into the system. The formulation “I have never found the philosophers’ stone” may be ascribed cognitive meaning without introducing a concept ‘I’ that makes the “I” something permanent. In a way, it is more reasonable that one will be less likely to find the philosophers’ stone as one’s “I” becomes less durable.

Cassirer may perhaps be blamed for having applied a neo-Kantian perspective to the “I” too early in his presentation of Hume. If one’s account is to be cross-systematic, one must try to give each system every possibility of maintaining consistency and totality. Whether a philosophically committed person can manage this is an open question; however, without commitment it makes no sense even to try to understand a single system.

Both Hume’s and Kant’s systems are pyramidally formed. From certain basic principles, rules, and methods the “rest” of the system emerges. Since Hume and Kant do not start with the same principles, rules, and methods, they do not place the same topics on the apex of the pyramid. The result is,

for example, that part of what Kant places on top is far down in Hume's pyramid. If we, perhaps unconsciously, use Kant's system (in weakened form) in our representation of Hume, we will see Kant as more profound than Hume. For we notice that Hume places certain things (for example, the concept of the stream of perceptions) at the top, but Kant places them somewhat further down in the pyramid. On the other hand, we do not notice that Hume goes beyond some of Kant's top-level concepts and sentences (for example, the existence of synthetic a priori sentences in Newton's physics).

The preceding is not meant as a criticism of Cassirer, but rather as an example of the difficulty or impossibility of creating an idea-historical crossing from one philosophical total view to another. Either one relies on the fiction that identical words have the same meaning for different philosophers, or one goes deeper than the purely verbal and accepts that the same words can have different meanings. In the first case, one obtains an easily intelligible but fictitious continuity or identity of problems. In the second case, resorting to the nonverbal, the comparability tends to cease. In other words, either one is forced up to the surface of the system, or one remains in the deep but employs a system in which both philosophies are forced together, with the result that, at best, only one will fit adequately.

The discontinuous transition from intimate understanding of one system to intimate understanding of another can be systematized by imagining a reader who is familiar with Hume's texts without knowing Hume's name, and is then given an English text of Kant to read but fails to identify Kant as the author.

Let a represent the first sentence of the text by Kant. The reader, H , interprets it in the light of his entire reading of Hume (including nonphilosophical reading, we presume). The interpretation may be symbolized thus:

$$(1) \text{Int}_H(a)$$

Where, in accordance with the symbolization outline in my *Interpretation and Preciseness* (1953: 115; a revised edition appears as volume 1 of the *Selected Works of Arne Naess*), (1) refers to the interpretation of sentence a made by person H , a reader familiar with Hume. It is naturally a Hume-systematic interpretation.

Upon reading assertion a , the reader is taken aback because it seems obviously erroneous or inconsistent with earlier texts. Let us assume that the reader guesses that a is written by another philosophical author and that he therefore does not take the “inconsistency” as an objection to the interpretation. He then reads the next sentence, b , and adopts the following interpretation:

$$(2) \text{Int}_H(b, S:a, \text{Int}_H(a))$$

Where (2) refers to a Hume-systematic interpretation of b in the context S with elements a and the interpretation $\text{Int}_H(a)$.

This proposition, however, clearly seems wrong or inconsistent with a , so the reader attempts other interpretations. He ultimately embraces another interpretation of b , which, nevertheless, recognizes that he was aware of and considered (2):

$$(3) \text{Int}_H(b, S:a, \text{Int}_H(a), \text{Int}_H(b, S:a, \text{Int}_H(a)))$$

which can be rewritten in shorthand form as:

$$(3a) \text{Int}_H(b, S:(b, S:a))$$

This proposition, while not obviously erroneous or inconsistent, still seems incomparable with the Hume texts. The reader now seeks a better understanding of a in light of (3) and finds a new interpretation of a :

$$(4) \text{Int}_H(a, S:b, \text{Int}_H(b, S:a, \text{Int}_H(a)), \text{Int}_H(b, S:a, \text{Int}_H(a), \text{Int}_H(b, S:a, \text{Int}_H(a))))$$

This situation can also be abbreviated to avoid making it completely unsurveyable:

$$(4a) \text{Int}_H(a, S:(b, S:(b, S:a)))$$

We now have a new interpretation of a in light of the “accepted” interpretation of b . This new interpretation of a may engender a rethinking of the

DESCRIPTIONS OF MAXIMALLY COMPREHENSIVE PERSPECTIVES

“accepted” interpretation of $b, (3)$, yielding an endless recursive process or a validation of (3) .

These symbolizations refer to readings of only two sentences of Kant’s text. Unless “intuition,” with attendant certainty, rapidly brings the reader further, the interpretation complications become stultifying. On the other hand, one has no guarantee that the “intuitions” increase one’s understanding of Kant’s intentions. In any case, the eventual understanding of the Kantian view in question results from a very complex process that is never entirely free of the influence of Hume and that, perhaps, may never be completed.

What I have tried to convey, roughly formulated, is the problematic character of writing an exposition of a philosophical system in general and of an all-embracing one in particular and, furthermore, the even more problematic character of a cognitively acceptable description of the movement from one system to another, whether as systems or as part of a history of ideas. The problematic character of all this, however, does not necessarily impinge on the present and future cultural value of philosophical systems.

II

Comparison of Different Total Views

Common Sense, Ordinary Language, and *Lebenswelt*

When comparing different systems, one must first consider all explicit definitions. All defined words (all definienda) are omitted and replaced by their definientia. For example, when a philosopher employs the word *substance*, but defines it, there is every reason to replace the word with the definition in comparisons, because other philosophers can easily mean something different by the word; likewise, if a philosopher has theses about empiricism, but defines *empiricism*. Of course, the definitions will deviate substantially according to the positive or negative attitude of a philosopher. At the outset, one does not assume that words from the vernacular are used in any special sense that has to be taken into account in order to understand the system. (Exceptions may occur, however. Some philosophers—Heidegger, for example—apparently use everyday words in unusual ways.) In accordance with this, one also assumes that the comparer's everyday speech is neutral in relation to the systems compared.

A great problem can now be formulated as follows: is it feasible to make everyday words and sentences more precise so that a conceptual system results? If it is, all systems would contain a common core. However one varied the systems, the variations would never affect the implicit concept world of the vernacular.

An obvious possibility is to identify the supposed conceptual and propositional system of everyday speech with a commonsense world picture. The philosopher's task, then, is to seek a kind of clarification and harmonization of the commonsense world image, not to *correct* the commonsense world at any point. The notions of a common, changeless, universal human *Lebenswelt* also belong here ("the fourth Husserl," and others).

COMPARISON OF DIFFERENT TOTAL VIEWS

On the basis of, inter alia, empirical, semantic investigations, I have concluded that words and sentences of the vernacular in everyday use have a depth-of-intention contour that does not permit one to make intra-intentional and plausible precisations in such a way that specific systems of concepts and propositions emerge. The depth of intention in a philosophically relevant direction is insufficient.

Precisely this characteristic—that everyday speech is philosophically amorphous—makes it suitable for system comparison in its first phase. It allows for histories of philosophy; the historian can converse in everyday speech about philosophers and their different theories. The speech is not philosophically adequate, but then this cannot be the historian's goal either.

One of the most interesting attempts at catching everyday speech in philosophically relevant conceptual networks was carried out by Ottar Dahl (1956) in his investigation of historians' use of the word *because* and certain other related words and expressions. His efforts to catch such everyday speech in this case were stymied, especially so in the case of top historians—those who do not mix philosophy or other subjects into their historiography. The use of *because* among historians is neutral in relation to concepts of cause and doctrines of historical causality of different systems.

Our conclusion, as suggested, is that words and sentences of everyday speech have a depth-of-intention contour that precludes the emergence of systems of concepts and propositions from plausible interpretation. This conclusion contains an essential restriction: that it be a question of words and sentences of the vernacular in everyday use. In other words, a vague but important demarcation of a field of situations or use is indicated. By precisizing the conclusion in certain directions, we can, owing to this demarcation, push it into the analytic. It is indeed in those directions that we intend to go.

There is no possibility of delimiting an everyday language that can be specified and rendered independent from a kind of function or use that is one of "everyday" speech. In everyday speech, certain words and sentences are used in certain ways. The *same* words and sentences are used in other ways in other kinds of situations. The vocabulary of everyday speech is common to the systems, but this does not imply that there are certain concepts or propositions that are common. When we eliminate all technical words and technical sentences from a system formulation, we have a system that is expressed in the vocabulary of everyday speech, but we do *not* get a variant of common sense, a system within the "concept world" of daily life,

in other words, a *Lebenswelt* philosophy. David Hume and George Berkeley, for example, attached importance to avoiding technical terminology, but their philosophies do not therefore stand closer to common sense or *Lebenswelt*. Richard Avenarius employed an enormous contrivance of technical words and sentences, but he is at least as close to common sense or the *Lebenswelt*. In fact, he is much closer, I believe.

As a system is developed, the words and sentences of the vernacular acquire more definite senses in relation to a technical conceptual framework. The vocabulary of everyday speech is drawn into the system; it becomes precizable—more exactly, sender-precizable—for the system builder in a philosophically relevant direction. For one who seeks to “dwell” in the system—for example, to see life as much as possible *sub specie aeternitatis*—everyday speech is also infected. In a certain sense, “daily life” ceases to be daily life anymore for the philosopher, but he can make himself fully understood in daily life through everyday speech.

If two philosophers who have radically different systems put forward a series of mutually comports sentences in the vocabulary of the vernacular, this cannot be taken as an expression of mutually comports propositions. The difference in propositional content is difficult to express. The system builder has not defined the words of everyday speech.

In view of this, it is not strange that the system builder finds it difficult to be understood and that it sometimes seems to him that neither critics nor adherents understand him. Edmund Husserl has stated, “All the criticism that I know of has missed the basic idea in my phenomenology by so much that it has not been hit at all, in spite of the quotation of my words” (Fink 1934: Husserl’s foreword).

In a letter to Karl Löwith in 1937, Husserl adds:

Maybe you understand that Scheler, Heidegger and thus all previous “pupils” have failed to understand the true and deep meaning in the phenomenology—in the transcendental phenomenology as the only possible one—and how much that depends on this meaning. (Husserl 1959: 50)

Buytendijk says in his assessment of Husserl’s importance for modern psychology:

One would be mistaken if one considered the rapidly growing frequency one can observe of the words *phenomenon* and *phenomenology*, *intentionality* and *act*,

COMPARISON OF DIFFERENT TOTAL VIEWS

Lebenswelt, put in parenthesis, essence-view and intuition in psychological treatises as a clear sign of an immediate and decisive influence from Husserl's side on the development of psychological thinking and methodological principles.
(van Breda and Taminiaux 1959: 78)

For the person comparing two systems, the preceding is of great importance, because the composer himself ordinarily seeks to describe the systems precisely in the vernacular. He seeks to express the systems "neutrally," hence either in everyday speech (so he thinks) or in a third system-language.

The vernacular used by a systematician who speaks within the system, and hence is not concerned with leading someone into the system, is *not* neutral. Words and sentences have meanings that can be precized within the frame of the system. They are not precized in the systematic account, but they may be made precise. They are intersubjectively precizable, but not sender-precizable for the systematician himself. When leading others into his system, the systematician can precize what he means for them.¹ To himself he cannot precize, however, if he is completely clear in his system and the system is fully constructed.

Comparison and Evaluation on the Basis of Adequate Presentation

Human beings are evaluated by each other. We accept this or that declaration as an expression of person *A*'s opinion of person *B*, regardless of how little *A* knows about *B* and regardless of how superficial and indirect the connection between *A* and *B*. We do not say, "You have not evaluated *B*, because you do not truly know *B*, the whole person *B*. You have merely seen *B* mentioned in a newspaper and you evaluated something that you more or less associate with *B*'s name. It is not *B* you have formed an opinion about, it is a fictitious person."

Usually we do not demand that a comparison and evaluation be performed on an adequate basis. The opinions of persons *A* and *C* about person *B* are independent of how *A* and *C* define *B* or indicate *B*'s essence (in Spinoza's terminology). In daily life I can say, "I do not really know *B*, but I am entirely opposed to the ordinary opinion of him." Of *him*. As if one had been in contact with the whole person and reacted to the whole person!

If we now conclude that we almost never compare and evaluate—we only think we do—then there is little left of what we usually do. Suspicion arises as to whether it is not merely misunderstandings (mostly philosophical) that have led us to criticize the modes of expression of daily life. From this viewpoint we are tempted to postulate that we *can* compare, and that when *A* and *C* disagree about *B*, it is precisely about *B*—an identical, common object—that they differ. That *A* and *C* do not agree at any point about the representation of who *B* is, apart from his name and elements of his appearance, cannot have any relevance.

If this commonsense attitude is applied to philosophical systems, we are liberated from the problem of whether presentation and evaluation are possible—since they are frequently done, they are of course also possible. Everything that *is*, is possible. In Spinoza's own system, precisely *his* standpoints have been represented and evaluated in different ways owing to differences in the people who encountered them.² Whether or not Spinoza's system is total makes no difference, according to such an attitude; one expresses one's own opinion and likes or dislikes about Spinoza. The depth of intention does not need to be greater than that of a mouse that nibbles on books by various authors and also has its own likes and dislikes, based on their paper and binding—a basis sometimes also employed by the highest mammals.

When we realize that this is the case and always has been the case, we become incapable perhaps of imagining clearly what it might mean for things to be different. How could clear but unsatisfiable criteria of representation, comparison, and evaluation have originated? Most likely thought ran amok. It turned to idling. The evidence of this is that when such comparisons and evaluations are consistently carried out, they frequently in practice lead to unacceptable conclusions—conclusions one will not accept.

It is healthy to keep in mind this commonsense or naturalistic attitude when the speculative and reflective consciousness leads to results that are peculiar or paradoxical, to put it mildly. An attitude, however, has no direct application to a way of thinking. If one's train of thought forms a chain—if *A* then *B*, if *B* then *C*—it may be criticized by evaluating premises or deductions. Attitudes do not enter into the picture. Regarding the premises, many things are relevant—correspondence with observation and so on. For the rules of inference, a more limited, logico-semantic kind of criticism

COMPARISON OF DIFFERENT TOTAL VIEWS

is relevant. That the conclusion, *C*, seems paradoxical or absurd in a sense other than (logically) self-contradictory or false cannot be employed as an intellectual criticism of the train of thought.

If the conclusion regarding deliberations about systems is that no one has accomplished a comparison of *total* systems, it is not necessarily a valid counterargument to say that adequate comparisons have actually been undertaken. We must object to premises and rules of inference, including the semantic rules, not the least of which are the definitions of *comparison*. If the definition of comparison is such that it requires something other than, or much more than, the demands that are generated from precization in at least one plausible direction, then one can perhaps on a semantic basis construct arguments against its feasibility.

If we are to list requirements for the adequate comparison of systems, we can learn from the basis of comparison employed in responsible art criticism. A critic must hear the entire piece of music — know the score, be present, and be seated in a location that is satisfactory acoustically during the entire performance. With regard to paintings, the critic must see the entire painting. Here, then, it is not the same as when personalities are compared in daily life.

To present Spinoza's philosophy to an audience (for example, oneself) requires more than just copying and rendering it, in Spinoza's words, one by one. It involves a communication of the thought-content, at least in its essentials. Hence, if one of Spinoza's main points is that "Everything that is, is either in itself or in something else," the representation must impart precisely Spinoza's intent regarding this point. If one does not know about the formulation, does not understand it, or does not include it in the presentation, then the presentation will not be adequate. If one does not include any other main point either, it might be proper to say that the presentation "is really (actually, strictly speaking, indeed) not a presentation of *Spinoza*." In examinations in philosophy in which a student "mistakes" one philosopher for another, we say that he did not "give a representation of Locke, even if he explicitly speaks about Locke all the time."

From the preceding, it emerges that an adequate representation of a philosopher's doctrine must be based on hypotheses about how the philosopher himself understands his individual sentences and their connections. An evaluation of a system must be presupposed to be an assessment of the thought-content intended by the system's author. Hence, when comparing

two systems, the comparer must collate two sets of thoughts. It may then *perhaps* turn out that the two doctrines that one assumes answer the same questions actually have no common reference points, meaning that they, strictly speaking, have no single object or theme in common.

I have emphasized “perhaps” because it is likely that the fewer points of contact there are, the greater the differences the metasytematician must catch in his net. Against this, we might object that the two philosophers may well have ways of viewing things that differ only in small but characteristic nuances. The world and self may have a somewhat different coloring for the two, or a somewhat different distance. To one of them, everything may seem nearer than to the other, and the proximity is not perceived as a property of the relation between things (entities), but as an essential characteristic of the things. If something like this can be the case, the two philosophers perhaps have no object in common, since the distance accent differs and applies to everything.

Even if different philosophers use the same words, we must be careful not to assume or postulate the identity of a basic concept or object just because it is expressed or designated by the same word. The question of identity is something that must be demonstrated independently of the similarity of words. *Being* and *existence* are examples of words whose different usage by various philosophers has led to a belief that the philosophers make statements about exactly the same thing. The statement “God is, but does not exist,” for example, is interesting because it directly employs the subtly different meanings of these words.

Discussions about the concept ‘substance’ sometimes conceal the belief that one is referring to a common fundamental concept or an object that has been common to philosophers for centuries. Do Descartes’s, Spinoza’s, and Leibniz’s so-called doctrines about substance have any identical object in common? Or is the occurrence of the word *substantia* confused with the occurrence of a common concept ‘substantia’ or with a common entity called substance?

It is essential to note that the occurrence of a common word, *substantia*, does not imply common use. The word can have common functions, such as expressing a fundamental ontological concept, but such functional similarities may serve as much to mark differences as to mark conceptual similarities. An assumption that a common use is at hand is a type of synonymy hypothesis, and it must be treated as a hypothesis.

COMPARISON OF DIFFERENT TOTAL VIEWS

That Spinoza and Descartes do not have the same substance-concept is the most plausible working hypothesis in view of their own definitions of *substantia*. Their definitions are very different. Descartes defines it as “Everything in which there resides immediately, as in a subject, or by means of which there exists anything that we perceive — for example, any property, quality, or attribute of which we have a real idea, is called a *Substance*” (Descartes 1931, vol 2: 53). Or more precisely, “Any thing, *A*, in which something, *B*, inheres immediately, as in an object — or by virtue of which something, *C*, that we perceive, exists — and this, *B* or *C*, is a property or quality or attribute of which we have a real idea, any such thing is called substance.”

Spinoza’s definition, on the other hand, is: “By substance I understand that which is in itself and is conceived by itself: that is that whose concept does not need the concept of another thing, of which it must be formed” (Spinoza 1914, part 1: 1).

When the definiens formulations of two thinkers are as different as they are in this case, the presumption is that they express different concepts. The burden of proof lies with the one who claims that the concepts are identical. Furthermore, it is easy to believe that the term *substance* in these cases denotes something different. This assumption, however, may be a mistake, because two different concepts may have the same extension.

Evidence that Descartes and Spinoza have different concepts for substance emerges with the first suppositions that they derive.³ Descartes concludes that the soul (*mens*) is a substance, while Spinoza finds that it is not a substance at all, but a *modus*. We can accept both derivations as long as we also accept that the two philosophers have different concepts for substance. If we hold that Descartes and Spinoza have the same concept (if so, which one?), it becomes difficult not to reject at least one of the derivations as erroneous. Hence, we must say to either Descartes or Spinoza: “The soul in the concept of substance that you hold, but have not defined yourself, is assigned an ontological status opposite the one you say it has. You have unfortunately made an error in your derivation. If we correct it, you will see that your philosophy is actually somewhat different from what you have thought.”

The preceding account of the difference between Descartes’s and Spinoza’s systems with respect to the possible concept or object expressed or denoted by the common word *substantia* is written within the frame of a se-

mantics in which the Semiotic Triangle is employed. The account might also have been written in a somewhat different frame. The more an account is made precise, however, the more a metasystematician must make use of a system and, furthermore, the more one's conclusions cannot be identical under variations of this system. Hence, the investigations with points of departure in Descartes's and Spinoza's texts will themselves be perceived differently when the semantic system is varied.⁴

For the metasystematician, it is easier to compare two systems based on the assumption that the two systems have at least one fundamental concept in common, rather than that they have no concepts in common. The latter, however, does not make his work impossible. It is much worse if the systems do not have a single rule in common and hence have no rules of inference—implicit or explicit—in common. This is particularly difficult since the comparer himself has a set of rules whose terms he must use to understand the authors: that is, he must ascribe and acknowledge understandability to them in terms of his own basic rules.

The distinction between the three classes—adequate representations, inadequate representations, and nonrepresentations—can, of course, be subjected to a critical examination. One may object to setting the requirements of adequacy too high in relation to a plausible development and sharpening of the requirements of daily life, but the concepts I have suggested can hardly be challenged in that respect. One must distinguish between principle demands of adequacy on the one hand, and practical requirements in the spirit of compromise on the other hand. The latter cannot replace the former without misconstruing the goal of representations.

Comparison with Respect to Truth-Value

When we compare two standpoints with regard to truth-value, we may definitively conclude that both are true, that both are false, or that one is true and the other false. (The result may be definite without necessarily being *certain*.) If the standpoints are not comprehensive or not very deep (merely scratch the surface), the result of the comparison may be justified by referring to a set of statements that we immediately accept as true. Such statements then acquire the character of standards and paradigms. The standpoints are confronted with the paradigm set and accepted or rejected depending on whether they agree or disagree with that set.

COMPARISON OF DIFFERENT TOTAL VIEWS

Already in such simple comparisons, then, it is obvious that a “third system,” a basis for comparison, a *tertium comparationis*, is implied. It provides the standard of truth or falsehood against which each of the statements is judged.

Is it different with measurements of length? Apparently not. Instead of quantitatively comparing the length of two lions by means of a yardstick (as a third “system”), we can put the two lions side by side and see directly which one is longer. The standpoints that “Lion *A* is longer than *B*” and “Lion *B* is longer than *A*” are compared simply by looking at the lions. If the lions are put in their position by competing hunters, a certain minimum of apparatus may be necessary. For example, we might need to place some straight sticks perpendicularly to the longitudinal direction of the lions, so as to establish a “zero point.” We then need to establish a set of rules with regard to the manner of estimating the longer lion, a criterion for deciding that “*x* is longer than *y*.” The criterion is not a part of zoology; it is brought in from outside.

If we arrive at contrary results, we must either examine the statements of the hunters for self-contradiction, or perform another measurement that then constitutes the standard, the frame of reference. Hence, a system is created if there is not already one at hand.

We may conclude, then, that the isolated comparison of two statements with respect to truth-value is not possible, if by “isolated comparison” we mean that no third statement at all is introduced and accepted in advance as true. Furthermore, a methodology is presupposed whereby one can *find* truth-value, and possibly probability, tenability, or other qualities in case one finds that truth cannot be found immediately.

Limits of Precision and Depth in Comparison

Let us imagine that a serious debate develops in which one person, Peter, justifies his standpoint by claiming that it is tested in his way, and another person, Paul, justifies his own standpoint by saying that it is tested in another way, Paul’s way. Peter justifies his point in his way, and Paul justifies his in his own way, and both reject the other’s justification.

The chains of justification come to an end, and if there is disagreement about the deepest links, the question of truth must remain open. The chains may perhaps be continued, and the participants may change some of

their opinions, but insofar as there is disagreement about the underlying theoretical principles, the question of truth is undecided. The deeper a dissension lies, the more slender the basis for a conclusion other than "undecided."

Something else also becomes apparent when standpoints are justified deeply: it becomes more and more difficult for the opponents to understand each other. Peter says, for example, that in the final analysis such and such is clearly evident. Paul says that something contrary is clearly evident. Then they offer long lists of evidence justifying their claims. Different philosophers have great difficulty understanding each other when the discussion takes such a turn. The result is that not only is the truth-value of their standpoint questioned, but also the very meaning of it. For example, one party does not understand *exactly* what the other means by "point at," "show that," "explain," "mean that," "believe that," "reply to," and so on.

Deep differences arise when it appears that Peter and Paul adhere to different concepts of truth. Peter thinks that truth and falsehood are something different from what Paul says they are. This may affect all statements they make, including anything they say about what truth and falsehood are.

I have spoken until now about Peter and Paul and the possibility that their world pictures are so different that comparisons of truth-value and meaning from their respective standpoints are not or cannot be undertaken. For each party, the other's system is false or meaningless. From the standpoint of a third party, however, the "Ashlad," this conclusion is highly suspect. Does the Ashlad understand both Peter and Paul? Does he have a system doctrine that does not presuppose either Peter's or Paul's special premises, but instead is neutral and wide enough to formulate the opinions of the other two? If the Ashlad does manage this, it is natural for him to say that Peter and Paul are each right in their own way. Their systems are relative, and thus truth is relative. This, however, leads us into a blind alley.

Two reasonable possibilities exist. Either the Ashlad's thinking goes deeper and thereby makes Peter's and Paul's opinions comparable with respect to truth and meaning, or the talk of relative truth no longer applies in this case. Peter and Paul have gone to the bottom and represent (nearly) total systems; in this case, the Ashlad cannot stand outside.

It is pertinent to ask how it is possible to speak about the difficulties of Peter and Paul. The answer lies in the vagueness of everyday speech and our

COMPARISON OF DIFFERENT TOTAL VIEWS

limited depth of intention. We do not need to have definite, sharp thoughts to obtain a feeling of understanding, but if we try to think as precisely as possible, we become more and more dependent on increasing both our depth and our breadth. In such attempts, it becomes clear that the Ashlad cannot describe what happens with Peter and Paul without speaking in terms of a definite system himself. His neutrality ceases, and with it the decidability of the questions of truth and meaning that Peter and Paul cannot decide. The Ashlad himself becomes hopelessly involved and has merely complicated the matter: we are left with an undecided debate among three parties instead of two.

III

Metaphysics as Exposure of Presuppositions

Collingwood's Concept of Presuppositions

The points of view of English philosopher and historian Robin G. Collingwood in relation to metaphysics warrant consideration.¹ Under the designation "metaphysics," he classifies Aristotle's first philosophy (*prima philosophia*), or doctrine of principles, and the traditions issuing from it, as well as the great system formations, regardless of their affinity to Aristotle.

Implicit in Collingwood's writings are (at least) three concepts of metaphysics (cf. Rynin 1964: 330):

1. " x is person P 's metaphysics," which means that " x is the set of (absolute) presuppositions in P 's systematic thought."
2. " x is P 's metaphysics," which means that " x is a clarification and representation of P 's presuppositions within P 's own systematic thought."
3. " x is a metaphysics," which means that " x is a text that presents what person P_1 hypothetically assumes to be person P_2 's presuppositions in P_2 's systematic thought."

Collingwood's concept of 'absolute presupposition' is interesting and valuable regardless of how one intends to connect or separate metaphysics and system theory.

David Rynin gives a condensed, nine-point characterization of presuppositions as Collingwood construes them. The following are his first six points (Rynin 1964: 308):

1. They lie at the base of systematic thought in the sense that by virtue of their logical efficacy they and only they enable its questions to arise.

METAPHYSICS AS EXPOSURE OF PRESUPPOSITIONS

2. They are not themselves answers to questions.
3. They are expressed in the form of declarative sentences, thus giving rise to the feeling or belief that they are genuine propositions, true or false.
4. They are not verifiable or falsifiable.
5. They cannot be undermined by experience, being the yardsticks (in some society) by which experience is judged.
6. They are not true or false.

According to Collingwood, “Every event has a cause” is a presupposition in relation to Kant’s system, but not in relation to all later systems. Other examples of presuppositions include “There is a God” and “Space is infinite.” Within statements such as these that articulate presuppositions, we can find concepts about ‘God’, ‘existence’, and ‘cause’ that function as basic concepts or categories of the entire system. They alone permit questions within the system to be posed and answered (Rynin 1964: 310–11). Presuppositions, however, also give rise to new questions; they generate questions, but they are not themselves replies to (living) questions posed by the systematizer himself. This is true by definition for Collingwood’s concept of presupposition (Rynin 1964: 310, 315, 328). Presuppositions are not statements in the ordinary sense, but rather expressions of the deepest faith—they are symbols that seek to express something that lies beyond complete understanding.

A person may be mistaken as to what his own presuppositions are (Collingwood 1940: 31). In other words, if *F* is a presupposition in relation to system *S*, then *F* is not part of *S*. Hence, one cannot speak as if there are presuppositions within or in a system. This point, however, is questionable and is discussed on pages 76–79.

Collingwood gives a concrete example of a presupposition in relation to a discipline. A physician, for example, determines the cause of a disease, and Collingwood asks why it must have a cause. The physician replies, “Because everything that happens has a cause,” and he adds, “That is something we take for granted in my work. We do not question it. We do not try to prove it. It is not something that someone has discovered, the way it is with bacteria or the circulatory system of the blood. It is something that we simply take for granted.” Collingwood responds, “He tells you that it is a presupposition in the branch of science in which he works” (Rynin 1964: 329).

The physician regards himself as a member of a specific profession with limited tasks. It is not difficult for him to understand that in other professions there may be other presuppositions, and he can, without any particular difficulty, articulate some of his own. In the case of philosophical systems, the situation is entirely different, since they encompass everything.

According to Collingwood, clarification of general presuppositions is of central concern not only for occidental, but for all cultures. The fall of Rome was, in the final analysis, attributable to the fact that the Romans lost metaphysical clarity, that is, clarity about the implicit presuppositions of the Roman civilization (Rynin 1964: 309).

A theory on the variation and constancy of civilizations seems to be implicit in Collingwood's concept of presupposition: If *A* is an absolute presupposition in relation to civilization *S*, then another presupposition *B* cannot later (or earlier) be so, if *B* is logically prior to *A*. If *B* is "There is one and only one space," *B* permits the question "Is this space finite or infinite?" If, on the other hand, the question "Is there one and only one space?" is posed, it is, according to point 3 (Collingwood 1940: 152), no longer posed in the civilization *S*, even if the persons involved might conceivably be the same. A new civilization *T* would be emerging, according to Collingwood's definitions in Rynin's versions. Likewise, if civilization *T* had "There exists one and only one space" as a reply to "Is there one and only one space?" and "Something exists" was an absolute presupposition, but a question in the manner of Gorgias was asked, "Does something exist?" then civilization *T* would be exceeded.

Not All Sets of Presuppositions Are Equally Acceptable

According to Collingwood, not all sets of presuppositions are equally acceptable. Conceptual tensions arise within a system that depend on the nature of the system's presuppositions. These tensions, which do not have to do with truth or falsity, may be of varying strengths, and if they become too strong, the system breaks down. This is the subject of some of the last points in Rynin's condensed characterization of Collingwood's views on presuppositions (1964: 309):

7. In a given system of thought they occur in clusters, no single absolute presupposition suffices to do the job.

8. To the extent that the presuppositions are not comparable, i.e., cannot be conjointly held without giving rise to inconsistencies and confusions of thought, they generate strains that, if sufficiently great, eventually lead to the collapse or alteration of that system.
9. Some clusters of absolute presuppositions exhibit fewer strains than others and are consequently better able to do their job of underpinning systematic thought.

Two Concepts of Presuppositions: One in Cognitive Daylight and One in the Twilight Area

Rynin is well on his way to accepting Collingwood's concept and doctrine in spite of being a logical positivist. To quote Rynin, "[I] am, I think, the only living logical positivist, or at least the only one who, as far as I know, is willing to be called this—provided that *I* explain what it means to be so" (1964: 331).

Rynin's strongly positive attitude is valuable and remarkable because Collingwood's doctrine is easy to attack, and Rynin is one of America's most merciless philosophical critics. Here I will not undertake a general analysis, but rather seek to clarify some sensitive questions.

It appears from Collingwood's examples that a philosopher can have a well-articulated presupposition expressed by an ordinary kind of formulation such as "Every event has a cause." Spinoza's first axiom, "All [things] which are, are in themselves or in something else," is a good example of a principle that is well articulated as a formulation and that the systematician has not at any point sought to go outside, as far as can be judged on the basis of our sources. The distinction "in itself/in something else" stands for Spinoza at the absolute limit of thought. It seems that the axiom does not emerge as a result of pondering the question "*Are* all things in themselves or in something else?" or other questions that the axiom then answers in good order. (With regard to Kant's "Every event has a cause," the case is more complicated since, at least when reading Hume, he must indeed have posed questions that "lie underneath" this formulation.)

For principles of the kind to which Spinoza's first axiom belongs, it is hardly the case that the author—or more correctly, the creator—is not convinced of their truth. They are true and self-evident for the system builder. If presuppositions are by definition beyond truth and falsehood,

and one uses the creator's intention as a base, then these kinds of principles are not presuppositions in Collingwood's sense. It seems that one needs two concepts of presuppositions, one on a level with what I have called basic sentences or basic rules *in* a system, and one that might be located just outside (before, under, or behind) the system, in a cognitive twilight area. Whether the latter can at all be constituted as a (tolerably precise) concept is something that I shall refrain from making a final decision about, but it is well worth the effort.

"All is connected," "There must be a God," "The world is evil," "Man is a nothingness," "I must not give up," "The individual human being has infinite value"—such exclamations or maxims are employed by many and can perhaps on particularly serious occasions exemplify the level on which the presuppositions that are "deeper" than the clearly formulated principles lie. It involves a matter of pronouncements with an expressive function approaching the artistic-expressionistic one. One is involved with all one's heart and has no energy left for a cool analysis. The pronouncements function as justifications in the sense that they put an end to further questioning or doubt. They cut short the discussion and clear the ground for getting on with life. One can then "proceed." Therefore, it seems almost quaint if one has misgivings, analyzes a bit, and tempers oneself: "*Almost* everything is connected," "Maybe there must be a God," "The world is almost or completely evil," "One might think man is almost a nothingness," and so on.

In the case of such exclamations it is obvious that the question of truth is not always relevant. "*Is it true* that there must be a God?" This question seems premature. Indeed, we *must* presume that there is a God! Alternatively, one enters the twilight area: "Yes, because otherwise everything becomes meaningless." If one then asks, "Why shouldn't everything be meaningless? Perhaps everything *is* meaningless?" and continues along these lines, one will most likely dig too deeply. The person who says "There must be a God" is no longer concerned; the questions are not living issues for him. The justification that is given for having to presume that there is a God is not an attempt to justify the truth of the "postulate." A compelling motive is indicated. To the one who does not feel it as a compelling motive, there is nothing more to say.

If we proceed from nonphilosophers or amateur philosophers to the great system builders, we are likely to retrieve such presuppositions from the twilight area. Some are explicit, but most are implicit.

In Spinoza's system, an identity seems to be presupposed between existence (as a human being) and perception (cognition), so that by realizing (knowing) something, one in a way "gets into" the things themselves—a form of spiritual occupation. Historians in this connection often quote the famous seventh proposition in the second part of Spinoza's *Ethics*: "The order and connection of ideas is the same as [is *identical* with?] the order and connection of things." This proposition, however, has been derived from something else *within* the system and does not concern the identity that is assumed "prior" to the system.

Collingwood points to a consideration of the basic concepts as a means to trace presuppositions. In the case of the twilight zone, this is clearly important. We can in a meaningful way ask about the justification of the distinction between God and non-God. What is it that justifies such a distinction? Spinoza presupposes that the reader of the *Ethics* comprehends the distinction between being in itself (*in se*) and being in something else (*in alio*). It is indeed possible that he has not allowed for the prospect that someone who knows the history of philosophy as he does will declare "I see no difference!" or "I cannot comprehend the difference!" Here is perhaps a basic structure in Spinoza's thought (founded, in this case, in a tradition in which he himself stands) that for him is "prior" to the system, in the sense that he uses it without asking about the justification for doing so.

Could Spinoza, however, have understood a question posed to him about the justification of the distinction? It is difficult to see why this would not be the case. We may imagine the question being posed by followers of Ockham, or another tradition in part coterminous with Spinoza. We leave open the issue of whether there are common presuppositions of such a kind that the one who uses them will in principle not be able to understand them without thereby rejecting something that is asserted in the system. If Spinoza had been able to give an introduction and justification of the distinction "in itself"/"in something else," what he justified in terms of it might have been grafted to the system as it now exists. The pyramid has acquired a new step.

Principles Within a System and Presuppositions of a System

If we re-examine Rynin's condensed characterization of presuppositions (pp. 83–86), we find that it suggests two concepts: principles within a system and presuppositions in relation to a system.

The category of principles applies to point 1, but we must add the proviso that it must be identified as basic to the systematic thought *within the system* it concerns. Point 2 applies similarly, but here too “within the system” should be added. Point 3 falls into the “presupposition” category, that is, sentences that are not principles but are nevertheless in the cognitive twilight area. To point 4 we must add “in relation to the system.” It is doubtful but not impossible that a principle in one system is a verified or falsified sentence within another, more comprehensive or profound system. To point 5 we must also add “in the system.” Point 6 applies to presuppositions and must perhaps be supplied with an indication of a relation: “They are not perceived as true or false (by the one who presupposes).” It may happen that one person’s presupposition is another person’s principle—for example, “We *must* believe that there is a God.” Points 7 through 9 are characteristic of Collingwood’s system theory. The question of their tenability provides a program for philosophical research.

These additions, which make Rynin’s characterization more explicit relative to a specific system, may well do Collingwood an injustice. In some places it seems as if he also has nonrelative concepts in mind: that it is a question of “absolutely absolute presuppositions” and not merely “absolute presuppositions relative to a system.” It makes sense for one who considers various historically existing systems to ask, Are there principles and presuppositions common to them all, and are there any that must exist in relation to any conceivable system, indeed to any form of systematic thinking at all? Are there presuppositions that make systematic thinking *möglich überhaupt* (feasible in general)?—are there necessary conditions of such a cognitive kind that they may be called presuppositions?

Collingwood’s main contribution lies in his studies of historically occurring systems and in his appeal for serious study of these systems—with the aim of understanding the foundation of one’s own civilization. He wants a “Know thyself!” approach to be applied to the study of civilizations—but a “Know thyself from within!” approach, not a study from the outside, such as a causal or natural science investigation. For Collingwood, this study is possible only by seeing one’s own system in contrast with that of others.

As a historian, Collingwood has no use for a philosophical system concept that emphasizes explicitness. Nor can he have any particular predilection for the special systems of outstanding, atypical personalities such as

Aristotle and Spinoza. It is, therefore, not to be expected that his system theory is adequate for the study of philosophical systems. True enough, the definitional statement here (pp. 11–12) can be made to cover Collingwood's system, but attempts to make it more precise will go in a direction philosophically that is not a historically important one. The main application of Collingwood's doctrine should be sought by historians and cultural anthropologists.

Collingwood's Metaphysics Presupposes a Supersystem

As long as we are sure that the systems created by others are inferior with respect to the breadth and depth of their conceptual structure, or at least not superior, then Collingwood's metaphysical program is sensible for exposing the presuppositions of all the other systems. In this case, one takes for granted that one's own methodology is entirely sufficient for comprehending another system. One will not take seriously the possibility that the other system might have a methodology, a doctrine of interpretation, exposition, textual analysis, observation, verification, and justification that in part conflicts with one's own. One will seek to clarify and explain all difficulties in terms of one's own system and will apply one's own methodology to the foreign system. If that system says something that does not agree with one's own, it is noted as a weakness, a lack of clarity, or an error in that other system.

Collingwood's idea for comparing the relative intensity of tensions within different systems can seem realistic, however, only if we imagine ourselves as supersystematicians with superior instruments of study. We must see clearly the highest goals of the others, but still perceive them as groping and stumbling. We must see how they stretch their arms out to reach what we have already attained, while recognizing that they will not quite succeed in achieving it. Others are led by conflicting wishes; their assumptions lead to internal contradictions; and they struggle to become clear about what happens to them, but they can never reach full clarity.

Throughout this, the system comparer does not consider the fact that he himself operates with a certain methodology and a concept of truth. If the latter requires something to be true, that it correspond with reality, his own conceptions of what can be real immediately become relevant. For example, if a system accepts the objective validity of norms, it must be possi-

ble that there is a reality of norms and a “world of values.” Do intersubjective accessibility and temporal permanence belong to that which one must require of reality? Or is a Heraclitean reality conceivable, in which everything is in flux—without a logos in the background?

To conclude that “This proposition (perhaps this principle) does not correspond with reality,” one must hold (at least implicitly) a theory about what signs indicate that a proposition agrees with reality. Does one rely on evidence criteria, sense experience criteria, or logical coherence? What about the applications of the criteria by a particular person—taking into account his own specific background—to decide whether the proposition agrees or not? What kind of “personology” can we presuppose that a person brings?

Already in the indefinite plurality of possible truth-concepts and criteria lies a source of misinterpretation of the other's system. If the other's system goes deeper and also *presupposes* another methodology, one has no chance to comprehend, let alone judge, his system. Since very few people can, or have occasion to, clarify their philosophical-systematical position, most evaluations of a system's truth-value are without cognitive value. The norm “You shall take a position!” works as grandiose deceit. One makes up one's mind, but without knowing with which system one is aligned.² Especially as a historian, one can be led to understand a system more or less deeply by immersing oneself in it without ever developing clear standpoints in relation to the issues covered by the system. Such an immersion tends to lead to a favorable evaluation. When one has an absorbing and understanding attitude, one's own thought acquires the other's style. The result is an evaluation from the inside, and any potential criticism becomes immanent and therefore irrelevant for the system as a whole. The evaluator has become a representative of the system, and therefore his potential to familiarize himself with other systems becomes almost negligible.

The original philosopher arrives at his standpoint through much labor. His pronouncements acquire their status via ongoing comparison with other standpoints. If the opposition disappears, the system's cognitive value also disappears. It loses its punch and has no personality. What remains is simply a terminology.

IV

Can There Be, Ultimately, Only One Valid Total System?

Are Total Systems Identical After All?

“Fundamentally, all philosophers agree” (Durant 1938: 185). Perhaps all controversy, all attempts by new generations of philosophers to assert oppositions to the old, is merely a gigantic example of pseudo-disagreement. In other words, perhaps the appearance of opposition lies in the fact that systematicians have not been able to “translate” among different styles of expression or different languages and that this has led to polemicized characterizations of each other’s work. Another possibility is that they *have* understood each other’s work but simply (1) assert that only one *style* of expression is correct and (2) believe that argumentation must be formulated as if disagreement concerns fact and not expression.

Felix S. Cohen (1939) argues for a principle of “logical tolerance” within philosophy and other disciplines. He supports the use of “transformations” that permit “every statement within a system to be transformed to a statement within any other equivalent system.” About the applicability of this principle within philosophy he says: “two philosophical systems may be so restricted in scope and so far apart in origin as to have no content in common. But increase the diameter or scope of the two systems and you have an increasing common content . . . [and there is] no content in either system which can not be reached and included by an extension of the other system” (1939: 61).

Cohen maintains that the content of a statement is, to a considerable degree, a function of the system in which it occurs. Expansion of the system’s scope should therefore affect the content of the system’s original statements. This is an important point with which I fully agree. Cohen, however, draws dubious conclusions from this point. When two, initially very different philosophical foundations are expanded to encompass the same

CAN THERE BE, ULTIMATELY, ONLY ONE VALID TOTAL SYSTEM?

scale, the differences decrease and become less important; that is, the differences become less cognitive and more verbal. When the “diameter” is extended, the reservations that philosophers must add to their original propositions lead to a gradual elimination of real differences in cognitive content. Finally, the differences become purely ones of terminology (see Cohen’s discussion of Spinoza’s and Leibniz’s systems as, respectively, modified monist and modified pluralist systems [1939: 62]). Cohen maintains that the distinctions between monism and pluralism “do not constitute a true-false issue . . . [rather] these differences are differences of structure, of perspective, of emotive value, social symbolism, or practical usefulness, rather than differences of objective content,” meaning that they are not differences concerning what is actually asserted (1939: 63).

The Spinoza/Leibniz example fits Cohen’s theory tolerably well, but when the approach is applied to Spinoza and Descartes it does not fit. To some extent, the content of a statement may be regarded as independent from the system in which it occurs, but I would prefer to consider the expansion of the system as an extension of the original idea so that it can encompass (explain, cover) a steadily increasing spectrum of phenomena. In order to understand a statement within the system, one must approach the fundamental vision, the basic assumptions on which the system is based and by which it is expressed. This involves appropriating, to a certain extent, the original systematician’s fundamental view. Cohen, on the contrary, sees the fundamental idea as merely an accidental effect of one’s point of departure.

The task of describing the world may begin at one specific point, but all roads lead to Rome. The more comprehensive the system becomes, the more it becomes a description of Rome itself instead of the journey to Rome. When considered as descriptions of Rome, all systems are equivalent. If the philosophers were not so semantically “ill-bred,” they would agree that they all say the same thing. Some historiographers have suggested something to this effect, but most often only in a mitigated form.

If all historically developed systems are “after all identical” in the sense that *the same is said about the same thing*, we might expect that historical research would find its way to this step-by-step, by seeing through and correcting all terminological disagreements. Historical atlases might even be published to show in detail how the same things are covered by different concepts.

A somewhat more moderate theory would contend that the systems *in all essentials* say the same about *essentially* the same things. Incongruities in the systems might be the result of the authors' own errors in the application of common principles or rules of inference—as well as different inductive inferences or different working hypotheses.

Specialist works that take up the fundamental assumptions of the great philosophers at a relatively high level of precision do not indicate any concealed identity of these systems. The phenomenology of philosophy points as little toward one philosophy as the phenomenology of religion points toward a single religion. Speculations about a common primal foundation, origin, or source cannot change this conclusion, even if one takes a favorable attitude toward the possibility of a common x (for example, with respect to basic intentions). The special literature on Spinoza and Leibniz, and their mutual relationship, may uncover similarities in intentions, but this does not affect the conclusion that, when one considers the expression of their systems in their entirety, the two thinkers' images of the world and themselves seem profoundly different.

The conclusion that deep comparison of philosophies does not point toward a common propositional content, however, is problematic. The designs for phenomenology of philosophy, like phenomenology of religion, are themselves parts of systems, and therefore, to a greater or lesser extent, are influenced by one's own position. There appear to be rich possibilities for different systematic designs of a phenomenology. Hence our conclusion can only be a guiding general pronouncement at the level of everyday speech. Attempts to make it more precise produce the standard complications involved in a doctrine of systems.

The well-known Oriental parable of the elephant and the blind men's description of it is worth mentioning: some latched on to the tail and took it for the whole elephant, others grasped the ears, and so on. The descriptions complement, rather than negate, one another. They are all correct as far as they go, but they are all incomplete. It is part of the story, however, that the individual describers were reluctant to recognize the incompleteness of their own characterizations. They embarked on a discussion from their different, partial systems, from their different elephant parts, as if they had the whole elephant in mind.

This view differs from Cohen's in that it completely recognizes the degree of difference in cognitive content in the case of fully developed cogni-

CAN THERE BE, ULTIMATELY, ONLY ONE VALID TOTAL SYSTEM?

tive systems, but justifies this by making an illicit analogy with mistaking one elephant part, perceived by oneself, for the whole elephant. Such a view is not compatible with an effort to compare Descartes, Spinoza, and Leibniz. It is no use saying that Descartes apprehends one part of reality (the ears of the elephant), Spinoza another (the tail), and Leibniz a third (the trunk). One who says this must be capable of knowing ears, tail, and trunk. Who is?

Reality is often said to be so rich that it cannot be apprehended by one person. Everyone is able to perceive *some* features, but no one perceives them all. The systematians make generalizations from within their small sectors or their limited perspectives, and polemicize because they do not recognize their limitations. This viewpoint sounds most convincing.

Who recognizes clearly his own limitations? This notion leads straight to paradox. He is a great metasystematician who is able to make pronouncements about *all* the systems, who must be conceived to be free from the oppressive naïveté and narrow-mindedness of others. We have in the preceding, however, explained sufficiently why such a metasystematician can hardly be found. Perhaps there is such an overwhelming *Geist*, a Hegel of entirely new dimensions and perhaps far more difficult to understand than the Prussian philosopher king.

Back to our point of departure, though. Let us imagine that we have a common system up our sleeve, that we have at our disposal a kind of map on which we can draw all possible systems. We should then, in principle, be able to make surveys and comparisons of systems without having to construct any new framework or metasystem. It is of interest, however, to inquire on what basis one can *demonstrate* that two systems are in fact identical in their foundation. Let us suppose that a Cartesian god (a nondeceiving, omniscient god) has whispered in our ear that all systems are identical in basic categories. Do we have criteria that enable us to discover the identity? Can we demonstrate that systems have a distinction between 'being' and 'nonbeing' as (part of) their foundation? Do they share the principle of contradiction? As far as I can understand, we would only be able to accept the dictum of the Cartesian god without argument; we could not remain critically questioning.

The father of all occidental philosophical systematics, Aristotle, sought an ultimate, absolutely certain, and self-evident foundation for all knowledge, and thought he had found it. His fundamental distinction was be-

tween “that which is” and “that which is not,” and his fundamental ontological principle was that any and every thing either is or is not. A third alternative is impossible. The concept of truth is connected with this fundamental ontological distinction and principle. ‘Truth’ is introduced by a definition to the effect that to speak the truth is to say about *that which is* that “it is” and about *that which is not* that “it is not.” ‘Knowledge’ may then be introduced as *knowing* (having verified) about something *that is* that it is, and so on. Thereby, we are already well on the way to an Aristotelian system construction.

The possibility for non-Aristotelian systems arises with the “primeval intuition” to guarantee the meaning and truth of the fundamental ontological principle.

Can we imagine that *that which is* in a certain, particularly qualified sense, cannot be ascribed any well-defined quality or characteristic, but is beyond human structuring? If we pose this question, we approach the problems in Plato’s dialogue *Parmenides*, in which “that which is,” in the eminently qualified sense, is the One, and cannot be ascribed the property of being! The request perhaps involves an absurdity. If one thinks, one thinks of *something*, and then one does not think of something else; hence, the principle of identity applies, and thereby the principle of contradiction. Thinking involves structuring.

Aristotle can (of course) incorporate these doubts in his own system by saying that the one who proposes a theory of the unstructurable already presupposes that something is either unstructurable or not.¹ Thereby, the ontological statement is already implicitly accepted by the one who seeks to doubt it, but the doubter can then question Aristotle’s attempt at incorporation.

Of more practical importance for philosophical-historical expositions is the question “Is there only *one* concept of ‘being’, the one that Aristotle seems to intend—considering his entire *philosophica oeuvre* (not just the place where he speaks about the fundamental ontological distinction)?” Actually, metaphysicians operate with different degrees and kinds of being. Aristotle seems, in the beginning of the fourth book of the *Metaphysics*, to want a very wide concept, one that is so inclusive that *that which is not* also *is* (namely, in the sense that one can say of *that which is not* that it is not). Other metaphysicians, and Aristotle in other contexts, introduce, or seem implicitly to presuppose, narrower concepts. A limiting case is the one in

CAN THERE BE, ULTIMATELY, ONLY ONE VALID TOTAL SYSTEM?

which *that which is* is identified with divinity, the One, the nameless, or that which is in other ways “highest” or “most” being. What does “being” stand for when being is graded and evaluated according to its kind? What is common to all degrees?

Aristotle’s truth definition can perhaps be made to cover all concepts of being, since it can be seen as an abbreviation for “True is the statement that about that which is—in terms of the criterion of being of subspecies *x*—says that it is in terms of the criterion of being of subspecies *x* or of that which is not—in terms of the criterion of being of subspecies *x*—says that it is not in terms of the criterion of being of the subspecies *x*. And this applies to all kinds of *x*.”

Nicolas Rescher and Robert Brandom (1980) distinguish between standard worlds and nonstandard worlds. The latter are inconsistent but may exist just as well as standard worlds. Although they may be rational, they violate principles that have been accepted as common for all system creations that refer to that which really *is* and not merely *seems to be*.

If all systems have identical basic categories, even if their authors do not accept this premise, then must those who in their explicit formulations take into account fewer kinds of being than the philosopher who introduced more types be supposed to have intentionally left the others unmentioned? Those who polemicize against the many degrees and kinds of metaphysical being would have to have misunderstood their opponents, or perhaps misunderstood their own systems. In this way one might try to keep a common framework for all systems, an expanded identity- and contradiction-principle, but I cannot believe that we will find such a framework, and I do not see the importance of finding one.

“The Common World”: Postulate or Reality?

The standpoints toward the possibility of the common world may be placed between two extreme limiting cases:

1. All human beings—including philosophers and poets in all cultures—respond to one and the same identical reality, but they respond in part in extremely different ways, and to some degree to different parts of this reality. Furthermore, they see reality from different perspectives, from different needs and expectations, and from differ-

ent talents and gifts. They throw different conceptual nets over the same reality and live to that extent in different worlds.

2. Human beings respond in all essentials similarly, but toward partly different worlds. Any individual lives, strictly speaking, in his own world. The situation to which man reacts is different and specific for each individual. Life situation, life space (Kurt Lewin), choice situation, and internal reality are different, and change with time for each individual, but talents, endowments, needs, expectations, conceptual nets are in all essentials the same. The different specific worlds are not parts of one comprehensive (unexperienced) common world, nor are they aspects of such a common world.

Conceptions other than those that can be pressed between these two extremes are worth close examination—for example, the one in which it is meaningless to claim that there are two radically different worlds or realities. Since we cannot indicate any experiences that could connect us with both, even indirectly, it is senseless to claim the existence, and hence also the possibility of the existence, of two. (If we were to experience both, we ourselves would become a connecting link, and thereby the two worlds would be combined into one.) This standpoint, which of course is based on a semantics and epistemology that is very much alive, might then be combined with the semantic claim that if a sentence is meaningless, then so is its negation. From the meaninglessness of "There may exist two worlds" the meaninglessness of "It is not the case that there may exist two worlds" follows. Now one world is a special case of "not two worlds," from which follows the meaninglessness of "There can be one world" and therefore also of "There is one world." All discussion of the one world disappears!

Many systems seem to presuppose that reality is one. The representatives of such systems think that what their system covers *is* that reality and that their system covers reality in an adequate manner (in all essentials), whereas the other systems fail to do so. The expression "stipulate a reality" is perhaps apt since it is not a matter of having found out that reality is singular, but a kind of requirement. Insofar as the expression is involved in a concept 'reality', and this is the one employed in metasystematic statements, it applies without restriction: "Within all possible systems, reality is regarded as singular." When one speaks of living in different worlds, or in general about the existence of different realities, one must employ other

CAN THERE BE, ULTIMATELY, ONLY ONE VALID TOTAL SYSTEM?

concepts of 'reality'; otherwise, inconsistency results. We do not have to discuss here whether systems that have only explicitly formulated concepts of this latter type must be said to employ the former implicitly (besides the others). I assume that no system needs to assume one reality if the unity involves more than something purely formal or something purely stipulative. That there is only one reality, or that there is at all a reality of the kind most systems say there is, is no more than a possibility if such a reality is conceived to be something of which at least one specifiable proposition is true, beyond what is said in the definition. Statements of the kind "The only reality has the characteristic *C*" may possibly be true, possibly false, or possibly neither (such as "The present king of France is bald").

It is usual to contemplate an atom as both a material object (or "physical system," to speak in textbook terminology) and a model. The same duality applies to a number of other entities. Does it apply to the world as well? The history of ideas, including the history of scientific ideas, can tell us about different world concepts. They have functioned as intellectual models in a somewhat wider sense than the atom. In the case of the atom, it is clear that a duality concept is not necessary. Various continuum concepts provide alternatives.

Does the same idea apply to the world models? Are we at all necessarily bound to employ world concepts? This seems doubtful. A kind of solution has to be found for the question before one makes a decision as to whether there can be several worlds. Most philosophers seem to accept that we all live in one, single, definite world.

Even if philosophical systems are incommensurable or if commensurable are contradictory, they nevertheless have one thing in common: they all deal with *one and the same* "world." There is something that is given for all. The world is that which philosophers struggle with: they seek order and meaning in it. It is an impossible thought that different worlds should be passed out (by God?) or that different sets of data should be distributed to different philosophers. If one could only manage to characterize the given in a neutral way, one would be able to describe the systems within a common frame of reference as different attempts at orientation in the same terrain.

The system comparer, however, would have to confront the systems in the same way that the rat psychologist treats his rats: he lets some of them out in a problematic field of mazes of his own construction and control,

while others are exposed to a cold airstream that blows on their tails when they must choose a path in a hurry, and so on. The rat-psychologist decides high-handedly what is to be called the right path and what is the wrong one. The rat has no say in the matter. The system comparer is no such super rat psychologist or supersystematician. Most system creators may imagine a *common* world (among the clear exceptions are Leibniz and Max Stirner, and others), but the system comparer has no special abilities that enable him to characterize such a common world independently from each system. He is in no better position than the others. From the moment he draws his first distinction, he is caught in a system—he has performed a system-constituting act: he himself is in the mazes, not in an armchair outside.

Everett Hall (1960) has introduced a concept of "categorio-centric predicament" or "category-centered dilemma" in relation to a similar problem: committing oneself to *special* categories that might have been chosen differently. Hall, however, accepts the given as something that all systems must tackle, and thinks that by assuming that something common is given, one avoids an untenable relativism:

[Each one of the various rival philosophical systems], in its dispute with the others, judged the issues in debate from its standpoint and used its categories to set them up. The world does not appear in its own right to decide this contest. One can get at the common object here only through the various rival characterizations of it. What to do? A sheer relativism that simply says, "Be happy with any philosophy which, by some chance, you have got yourself involved in, for there is no rational choice between them," will not do. This is indeed one of the contestants and should not be favored without reason above others. So we are faced with the problem of trying to get out of our categorio-centric predicament and coming to terms with the universe by means of something given to all philosophical constructions. (Hall 1960: 127–28)

Nevertheless, Hall's reflections about the given are marked by specific attitudes and positions that are not the only possible ones. His explanations do not provide any fixed point beyond the systems, a *corpus alef*. Indeed, elsewhere he seems also to state that he operates with certain categories. These are involved and make the hypothesis about the common given system relative.

To the world pluralism that I think is a living philosophical possibility, it is not in itself destructive to assume that all philosophers proceed from the "given," but then it becomes a completely formal category. It says

nothing about the given as content; nothing is said from a material point of view. The same applies to certain world concepts that can be used in combinatorial logic and in statistics: they are completely formal concepts that concern structuring, not that which is structured.

One approach is to work on the basis of a program: let us seek to delimit a commonsense world, our common world. Such a delimitation lies within the scope of modern social science insofar as one wants to arrive at a social net of relations. "The problem of social reality" may, I suppose, be posed as a completely research-worthy problem, as Alfred Schutz (1962–66) suggested. When one speaks about discovery of the presuppositions of the commonsense world, however, a serious problem emerges: where does Schutz himself stand during such a discovery and from where does he get his terminology? Columbus could discover America because he came from outside; the Indians he encountered could not. In his introduction to Schutz's *Collected Papers* (1962–66), Maurice Natanson makes Schutz's approach appear as a kind of intuition; he says that Alfred Schutz's philosophy "articulates a single intuition, the discovery in full depth of the presuppositions, structure, and signification of the common-sense world" (Natanson in Schutz 1962–66, vol. 1: xxv).

Schutz constructs a model of different strata in man's social reality. The whole schema is described as if he finds these very strata and places himself safely and securely by one of them, just as a geologist sits down by a rock and takes out his little hammer to break loose a piece in order to analyze it. Natanson writes that "[T]he taken for granted everyday world of living and working is the nuclear presupposition of all other strata of man's reality, and it is this ground of social reality to which Dr. Schutz turned and which he took as a point of departure for analysis" (Natanson in Schutz 1962–66, vol. 1: xxvi).

Natanson states further that the indispensable foundation for earthly existence remains unnoticed by ordinary men, even if their life is structured by and based on the mold of everyday life. "The philosopher's privilege is to render the taken for granted object of his critical inspection, and this indeed was the procedure of Dr. Schutz" (Natanson in Schutz 1962–66, vol 1: xxvi). This is possible, I suppose, but it can only be done from a system that treats "taking x for granted" ("the obvious") as an *object* for inspection. When N. N. crosses the floor, he takes for granted that it will hold up. To describe this view presupposes a structuring: floors that hold

are distinguished from floors that do not; the goal of not falling through a floor is derived from a more general goal of not hurting oneself. These goals are ascribed to the one who strides across the floor. The phenomenologist looks at N. N. as he crosses the floor, thinks of all that N. N. takes for granted, enters into N. N.'s way of experiencing—but from a system, a conceptual structure. One notices the structure when, as a phenomenologist, one thinks that one makes a mistake.

The model called "social reality," "commonsense world," or "our common world" tends to be underestimated. One postulates a social reality but does not think one has employed any model for this: indeed, the social reality is *just precisely* the reality in which we live. The situation is perceived in the same way that Karl Marx perceived communism in his *Die Deutsche Ideologie* (1938): idealism is an intellectual construction, but communism is *the development itself*. Communism is no ideology; it is not a name for a doctrine. The sentences that seem to express communism as an ideology have merely a kind of index function: they point to the very development itself in its progress. This is a completely natural way of speaking as long as one is within a system with all one's heart and brain. Then it is of course not perceived as a system, but if there is even a tiny discord in one's mind, one will sooner or later have glimpses of the system from outside. One is again in the maze of possibilities, a maze not of one's own making, but not of anybody else's either, . . . or so it seems.

Cultures Construed as All-Embracing Systems

“Philosophical Systems” as Designations for an Articulated View of Reality as a Whole

The aim of this chapter is to examine the extent to which problems dealt with in relation to philosophical systems also arise in relation to cultures. This especially concerns the possibility of describing a philosophical or cultural system within the framework of another system. It also concerns the possibility of comparing systems in a neutral way — hence without relying on the concepts of one system or construing the other in terms of them. In addition, we are interested in both examining the possibility of indicating criteria for the depth of philosophical and cultural differences and exploring the influence of these different levels of variance on mutual understanding and comparability.

It turns out that it is not easy to approach these problems without saying something about concepts of culture and modern cultural anthropology. First, however, a repetition of the system idea as applied to philosophy is needed.

Philosophical systems are verbally expressed by sentences, in part descriptive and in part normative. Each sentence has a sense (a meaning), in terms of the Aristotelian trichotomy, as: (1) linguistic expression, (2) sense or meaning, and (3) reference or state of affairs. The system becomes a *B*-entity.

The systems “pretend” to provide justified truth about reality, hence a kind of insight or wisdom. The unique characteristic of *philosophical* systems is that they refer in direct speech to reality as a whole. They address everything that is required to comprehend reality in all its essential and fundamental traits. They do not refer to every single thing in reality indi-

vidually. Such an approach would lead to an all-inclusive, detailed encyclopedia. The systems thus comprise more than what is ordinarily intended by such expressions as “the world,” “the universe,” and “nature,” but also less, since the details are not relevant.

From a historical point of view, a philosophical system is a construction. History reckons with an incessant development in the thinking of individual philosophers and acknowledges the fragmentary and context-determined character of all written texts. Philosophers conceived as historical persons do not write down systems in the sense of the expressions introduced in this work. Even in the case of Spinoza, one must take into account more than the central text, the *Ethics*. Spinoza’s unsystematic letters to colleagues are also a source when one seeks to describe what is called Spinoza’s system. The systems should be construed as units.

If one takes the *Ethics* in isolation, however, it is inordinately well suited as an example of a connected set of statements about reality, even if one does not fully comprehend the methodology and political philosophy. Within the cultural tradition to which Spinoza belongs, these subjects must be counted as important in descriptions of reality. If only for this reason, one cannot identify the *Ethics* with Spinoza’s system.

The main purpose of this chapter, as suggested, is to examine the extent to which the problems concerning philosophical systems that have already been discussed apply also to cultures. If the answer is something like “to a great extent,” then this must have consequences, not only of a theoretical nature, but also for national and international cultural politics.

Cultures as Information Economies

The analogy between philosophical systems and cultures cannot be made effectively without a certain simplification. Introducing some culture concepts will make the analogy less complicated. Those culture concepts that view cultures as embodying more or less uniform sets of normative and descriptive knowledge or information fall into this category. Because of the comparatively uncomplicated analogy with such a choice of concept, I shall begin the comparison of cultures and philosophical systems with the description of one of these concepts, the so-called information-economic one. It is strongly influenced by Euro-American information theory and social economics. The concept must appear rather peculiar from the point of view

of other traditions, such as the Indian, but that is, if anything, an advantage rather than a drawback in view of our special task in this chapter.

According to John M. Roberts (1964: 438), a culture is an “information economy” in which information is generated, stored, recovered, communicated, used, and in part also lost. A philosophical system, as the expression was introduced, corresponds to the content in the stored (cultural) information. The difference between two systems then corresponds to the difference between the stored information of two cultures.

About this storage of cultural information Roberts, among other things, says:

In any culture information is stored in the minds of its members and, to a greater or lesser extent, in artifacts. Since the four tribes under consideration [Chiricahua Apache, Mandan, Omaha, and Cheyenne] were preindustrial and nonliterate, it is not necessary to consider artifactual storage here. . . . For purposes of discussion it will be assumed that the entire informational resource of each of the four cultures was stored either in the heads of tribal members or in the heads of those nonmembers of the tribes with whom tribal members communicated. (Roberts 1964: 439)

Among the people who are *not* members are researchers from the industrial countries. They are the ones who have attempted to *describe* the cultures. Such descriptions belong in the information-theoretical category, in which *the stored content of the culture* is represented systematically in English or another language that is employed by cultural anthropologists from industrialized countries. This sounds straightforward at first blush but appears very problematic after closer analysis.

On the basis of the systematic, purely descriptive account, one might then conceivably formulate a system corresponding completely to a philosophical system, consisting of norms and hypotheses. Recovery of philosophy takes place by communication, the use by application in action, loss by imperfect communication, and in other ways. The same might be said about cultures. Thus, the analogy between cultural system and philosophical system is very clear in terms of the information concept and information theory of culture.

Conceived in terms of information theory, cultures may be more or less complex, and hence the individual members will in a lesser or greater degree be able to be carriers of great parts of the whole culture. According to

Roberts and Morris Opler, whom Roberts quotes, Chiricahua Apache exemplify the latter. They had no formal ceremonies, no institutions that only the leaders knew about. "An adult male and an adult female actually commanded a substantial fraction of the total Chiricahua Apache culture" (Roberts 1964: 446). A natural comparison is with the conditions in the medieval, extremely decentralized Lapland.

The circumstance that most cultures, to be preserved in their entirety, require many members, makes the analogy with philosophical systems somewhat more distant. In addition, special problems arise for the information-theoretic model when the content that is stored by one group, one particular profession, for example, is in part incompatible (inconsistent) with what is stored by another group. If ordinary axioms for " x is an instance of knowledge" are applied, x must not contain a set of inconsistent parts of knowledge. For example, if a culture contains assumptions about the kinship between persons A , B , and C , then the set of assumptions, x , cannot contain both " A and not B is the mother of C " and " B and not A is the mother of C " without losing its status as a coherent whole of knowledge. In other words, according to these axioms a culture cannot be represented as a coherent whole of insights if two so-called insights are cognitively incompatible. We will have more to say about this later.

Let us make the unreasonable assumption that we stand cultureless and are offered membership in a culture. In view of the preceding, this offer does not seem to be of quite central importance. As information economies, cultures offer various ways of generating, storing, recovering, communicating, using, and losing information. These are useful things, but useful for what?

Cultures as Total Forms of Life and World Images

In what follows, I take up a culture concept or rather a family of culture concepts that are akin to Roberts's, but that nevertheless differ sufficiently from his to give another shape to the problems we are addressing. I shall in all essentials keep to Fredrik Barth's accounts within the subject he calls social anthropology. It is very close to what kindred researchers have called cultural anthropology.

That Barth's concept has intimate relations to philosophical systems is suggested by some of his central statements (1977), for example, that a cul-

ture is a specific way of interpreting the world, organizing society, and finding the meaning of life.¹ A particular culture designates the main features of an intended organization of society and seeks to denote the meaning of life as an essential part of reality. The term *intended* is worth noting. A description of a culture does not have to include ways of behaving that are not intended.

It is presupposed that no culture exists that denies life a meaning. This presupposition is not decisive. Philosophical views that deny a meaning in life presuppose at least implicitly that a stand is taken on all branches of philosophy.² If the denial characterizes a culture, it will implicitly be all-encompassing.

Barth (1977) contends that “each culture can be understood as a world alternative to our own.” The wording here is close to my own in the question “Which world is the real world?” My response is, *inter alia*, that no single world can be pointed out as more real than any other. An analogous answer is given by Barth in relation to cultures!

Barth further assumes that each culture contains a wealth of traditions and visions of the good life. Analogously, I argue that the same holds for philosophies: such content is a necessary condition for motivating the exertion required for conscious development and verbal articulation of philosophies.

In a conversation in 1972, Barth mentioned to me that he estimated that there were several thousand such cultures on earth. Given the homogenizing effect of globalization and the stresses placed on indigenous societies, one can only conjecture how radically reduced the number will be in the future. I perhaps require more originality in a culture than Barth does, and thereby reckon with somewhat fewer cultures in the following analysis. In any case, numerical indications are highly arbitrary. The demarcation problem is similar to the one of distinguishing among languages and dialects. The number of living languages depends on where the line is drawn.

The word *tradition* is central in cultural anthropology. Its closeness to the concept of culture appears from the following statement by Barth, which is after all very similar to the statements about cultures. “Every cultural tradition defines premises and meanings of life for the population that carries it . . .” (1977).

“Cultural premises” and “system premises,” in the sense of nonderived descriptive statements and prescriptive rules, are not the same, but there is

a kinship between them that is important for the comprehension of both. Many anthropologists have indirectly presupposed such a kinship. “[I] have shown how nearly everything that happens in Kalabari life can be interpreted in terms of a scheme which postulates three basic *kinds* of forces: ancestors, heroes, and water-spirits” (Horton 1970: 133). Robin Horton, who made the preceding statement, contends that the system of explanation corresponds to the Western one in which atoms, molecules, and waves are introduced as nonobservable entities. The three sets of theoretical entities serve to introduce “unity into diversity, simplicity into complexity, order into disorder, regularity into anomaly” (Horton 1970: 134). Horton thinks that when anthropologists do not see the similarity, it is because they are unfamiliar with their own occidental cultural theory constructions (for example, as in physics).

I. C. Jarvie and Joseph Agassi (1970) emphasize that the strength of the magical worldview lies in its completeness. Everything can, in principle, be explained in terms of either magic or failed magic. After all, the difference between magical total views and “scientific” ones, argue Horton and others, is that the scientific tradition involves a permission to criticize theories and their basis. The relevance of this point for the problems in this chapter, however, is only partial. Cultures are more than total views of how events can be explained. They also contain, among other things, *descriptions* of that which needs to be explained.

Structure, Experienced Content, and Correct Conduct

A word that is central in cultural anthropology, as in many other social sciences, is *structure*. We use the word daily. A boat can have a beautiful, solid, complicated, or awkward structure. The structure of positions in certain universities in the postwar years was top-heavy: there were many professors and few junior positions. The structure of Ibsen’s dramas appears to be meticulously thought out. Barth (1977) says that “anthropologists seek to demonstrate the structure in each culture—how it constitutes a cognitive system, a set of codes for communication between people, and a world picture whereby they interpret their external reality.”

A whole series of deep questions might be posed by using this quotation as a point of departure. One of them concerns the relationship between structure and content. As fellow beings, we are interested in the cultural

content rather than the structure. The codes of communication are important, but in human relationships they are important only because they are necessary to obtain access to content. Can cultural anthropology as a science do more than describe the codes as part of structures?

The quote also suggests that the anthropologist seeks to show how the structure constitutes a world picture, whereby the carriers of the culture “interpret their external reality.” This formulation begs the question “How then does reality look, how is it experienced, when a carrier of the culture uses the code and the world picture in his interpretation of reality?”

My reason for posing the question is primarily culture-political. The ever better organized, but also constantly unsuccessful, attempts to preserve cultural diversity on earth presuppose that cultures differ not only in their structures, but also in their experienced content. This point of view presupposes that lived worlds must be different. It is not enough that the machinery differs.

To remind ourselves of this point of view, it is perhaps appropriate to let “world picture” stand for something more concrete than some code. The emphasis might be placed on perceivable entities, not merely an abstract representation, a model, or a world depiction. When applied, for example, to Ghanaian music, it involves an attempt to gain knowledge of how the Ghanaian music affects the listener and is experienced by him in comparison with how German or Norwegian music appears and is experienced. Hence, in addition to knowledge of structure, we must also consider knowledge of the experienced worlds and their mutual relationships. Some insight is obtained simply by asking. Ola Kai Ledang (1981) asked a chieftain’s son from Ghana what he thought of Beethoven’s symphonies. The spontaneous reply was, “For me the symphonies of Beethoven are not very interesting or valuable music. It sounds almost like a march all of it” (Ledang 1981: 22).

There is an essential difference between behaving “correctly” in a situation within a culture and experiencing the situation in the natural way that a carrier of the culture would experience it. A robot can, in principle, behave correctly, that is, within a wide or narrow frame defined by norms and hypotheses (seen from a system viewpoint).

Let us suppose that two anthropologists or a tourist and an anthropologist conduct themselves correctly in a foreign culture. Their levels of insight into that culture may nevertheless differ. Their depths of intention may be different. Deep comprehension of a culture is presumably impossi-

ble without *intimate familiarization* with the culture; this presupposes identification with the culture and thereby affective transference. At this point, too, the similarity between philosophies and cultures appears.

Erik Dammann describes his and his family's experience of attempting to *live* in a foreign culture:

The [Samoan] village itself had enthusiastically accepted what we in our naive ignorance said the first day: We do not want any separate treatment, we want to learn to live *your* life! In practice, this turned out to mean that we had to live more closely and more constantly together with them than we were used to even with the closest family at home. In order to manage such a form of common life, it was not enough to "understand" them. We had to become fond of them. (Dammann 1981: 25)

It is worth noting that "understand" here is in quotes. For if understanding refers to content and not merely abstract structure, then the researcher must to some extent experience the world the way the foreign culture experiences it. This means that in Dammann's Samoan village, people look at each other and perceive each other in ways that are affectively normal in terms of the Samoan culture's premises. Hence, the understanding has an affective aspect that cannot be detached from the intellectual one.

It is difficult to believe that a working anthropologist who seeks to enter as far as possible into a foreign culture does not, at least in glimpses, experience a situation very nearly the way a carrier of the culture does. It is, however, methodologically very difficult to confirm the degree of proximity.

If one emphasizes the uncertainty of this assumption of "glimpsewise" similarity, one must also stress a corresponding uncertainty within one's own culture. The problem is then no longer specifically a problem of cultural anthropology, but one that is relevant quite generally to the question of demonstrating interpersonal similarity or difference in experience.

The differences between the Baktaman culture and my own (Norwegian) are overwhelmingly multifarious and evident in all types of everyday situations, not just special situations such as participation in rituals or hunting. Suppose we try to list all the norms and hypotheses that are both relevant for the Baktaman during an arbitrary five-minute period of their everyday life and different more or less from life in Norway. I predict that there would be hundreds of entries before we got to listing their perceptions of their external surroundings (trees, paths, dwellings, light, shadow,

rain, sun, and so on). From a philosophical point of view with an emphasis on Gestalt thinking, the list would in principle be amenable to nearly limitless expansion.

All these differences are relevant for how the world and one’s self are experienced. They work together to form total experiences, not by summation, but by Gestalt laws—I suppose. Indeed, we can obtain more or less secure knowledge about the structure of such differences, but if we are concerned with culture content, we cannot avoid asking, To what extent and in what way can we experience five minutes in the way it occurs in the foreign culture?

Furthermore, we have the additional problem of the maximum possible difference in experience and the hypotheses of biological or other factors that can tell us about the limits of these differences. It seems unreasonable to assume that biological similarities, such as the make-up of human sense organs, do not determine limits of difference in experience.

“Culture,” ‘Culture’, and Culture

In the preceding we have in our reflections about systems first employed a rather special and relatively clearly delimited concept of culture: Roberts’s (1964) information economy. In addition, we have used a more diffuse, but intuitively more plausible concept presented in Barth’s paper (1977). That concept, too, makes cultures cognitive units, units of insight. In cultural anthropology, however, very different, much broader definitions have been prevalent. Let us consider three examples (Keesing 1974: 138):

1. The complex whole that comprises knowledge, art, morals, law, custom, and any other skill or habit that a human being has acquired in its capacity of member of society (Tylor).
2. The sum total of knowledge, attitudes, and habitual patterns of behavior that members of a particular society have collectively and transfer (Linton).
3. The man-made part of the milieu (Herskovits).

These ideas are clearly important for any description of culture, whether or not one includes artifacts in the description—that is, the cultural objects. Furthermore, if one includes factual, mostly statistical information

about learned behavior, or keeps to the patterns and norms of behavior, it becomes necessary to consider more carefully the semantic and the science-historical peculiarities of the word *culture*.

Like *democracy*, the word *culture* shows a high degree of ambiguity and vagueness—although this does not prevent it from being useful cognitively. On the contrary, such words may indeed be irreplaceable in political science and cultural anthropology, respectively. It is, however, important to avoid the illusion that such words stand for any specific cognitive content.

It is also important to understand the reaction in contemporary (1970s) cultural anthropology against an influential concept of culture that was developed by E. B. Tylor and continued by Alfred Kroeber and Clyde Kluckhohn. One of the leaders of the “reaction,” Roger M. Keesing, formulates it as follows:

[W]e increasingly realize that the holistic, humanistic view of culture synthesized by Kroeber and Kluckhohn includes too much and is too diffuse either to separate analytically the twisted threads of human experience or to interpret the designs into which they are woven.

The challenge in recent years has been to narrow the concept of “culture” so that it includes less and reveals more. As Geertz argues, “cutting the culture concept down to size . . . [into] a narrowed, specialized, and . . . theoretically more powerful concept . . . has been a major theme in modern anthropological theorizing. (Keesing 1974: 73)

The approach suggested by Keesing in this example is clearly profitable in the short run, but its value over the long run is more questionable. It turns out to be infeasible to obtain agreement about one concept as the scientifically fruitful one. Key words such as *culture* are simply not amenable (fortunately) to constriction in such a straitjacket. Attempts to standardize are likely to lead to unfruitful propaganda for the concept that suits the research of one’s own group in the short run. The compendia *Psychologies of 1925* and *Psychologies of 1930* provide discouraging examples from a related discipline (each psychologist has his own concept of psychology).

On the other hand, it is clearly fruitful to make *culture* more precise in special directions and use it in specific ways definitionally for particular purposes and in particular texts. Then, however, one introduces stipulative definitions without pretensions that everyone in the discipline, regardless of research program, should or can keep to the definitions.

The information-economy concept introduced by Roberts provides a good example of a precization of *culture* adapted to new, presumptively valuable, but very special research programs. In what follows I shall occasionally use the word *culture* the way it is used vaguely in the literature that Keesing characterizes as holistic and humanistic. I do not pretend that the word expresses any *specific* concept, but that the use, *if it is made more precise*, falls under the family of concepts that are also exemplified by Barth's use, hence a cognitive concept.

For the comparison between culture and philosophical systems, it is fruitful to eliminate noncognitive elements. It is helpful to keep to concepts of culture that do not include cultural products, such as paintings and ships. Similarly, one should focus on the rules of accepted practice rather than try to include all actual customs and their gross deviations. The intentions of behavior, not the way a society lives, then become part of its culture. The prescriptions for behavior, not the descriptions of behavior, become relevant.

With this precision, a culture demarcates an all-purpose set of norms and descriptions (of the world). In what follows, then, I keep to such a concept of culture.

The application of a cognitive concept of culture is, of course, not unproblematic. Suppose we film a dance. What belongs to the culture and what does not?

An older woman rises and dances out on the floor. After a while we understand that her movements illustrate what has happened.

At first she dances with bowed head and serious face. Sometimes she stretches out her arms imploringly, then she lets them fall again and dances slowly on with her eyes towards the floor. Then she suddenly looks up and smiles, grasps in front of her as if she receives something. The song becomes quicker, the clapping becomes rhythmical and fast, the old woman wiggles and hops merrily while she laughs and pats her plump stomach again and again.

It is not difficult to see what she represents: the hungry have received food and have become happy again. (Dammann 1981: 115)

For this culture, there are guidelines for the dance, the method of representing the historical material. In this case, the guidelines are the fact that the Dammann family in the village of Manase went almost without food for several days, and many other dramatic details related to this sad

event. Problems arise, however, when one wants to give a precise description of the cultural content of this dance. It becomes no less difficult to describe Erik Dammann's own subsequent dance, which was received with laughter, shouts, and vigorous applause by the community.

Now I tackle the question "Do similarities between cultures and philosophies disappear because philosophies have an appreciably higher level of integration and are furthermore assumed to be logically consistent?"

Integration Level and Consistency

The philosophies of Aristotle, Thomas Aquinas, and Spinoza — to take some prominent examples — consist of elements joined together with great accuracy. Researchers who study such philosophies usually hold that the mutual relationships of all the parts are carefully thought out — they are completely integrated in a consistent whole. Here, no deviation is tolerated. One might have another impression, but through specific interpretations that do not have to be completely unreasonable historically or by distinguishing the "mature" philosophy from fragments created during the philosopher's development, the researchers perhaps manage to verify that the system is consistent.

It is more realistic, however, to reckon with imperfect integration and only partial consistency, even if only a minority of specialists has such a view. In the case of Spinoza's philosophy, it is comparatively common among specialists to complain about the inconsistency in it. I myself think that it is, in any case, exceedingly difficult to arrive at an interpretation of the texts that embodies a clear, all-encompassing integration and consistency. Generally, I suppose we should keep our minds open to the possibility that philosophies may be highly integrated and consistent, while recognizing that perfection is hardly attainable and not at all demonstrable, thereby clearing away an objection in principle to seeing a close similarity between philosophical systems and cultures. Cultures are indeed incompletely integrated, and it is the anthropologist's obligation not to overlook this. According to Clifford Geertz:

The problem of cultural analysis is as much a matter of determining independencies as interconnection, gulfs as well as bridges. The appropriate image, if

one must have images, of cultural organization, is neither the spider web nor the pile of sand. It is rather more the octopus, whose tentacles are in large part separately integrated, neurally quite poorly connected with one another . . . and yet who nonetheless manages to get around and to preserve himself, for a while anyway. . . . (Geertz quoted in Keesing 1974: 80)

Even if the level of integration within a culture is never perfect, as sometimes seems to be presupposed when there is talk about cultures, it is easy to demonstrate deep connections. This can be done by using simple sentences as points of departure. Consider, "I am a parakeet" spoken by a Bororo (and translated to a kind of English) and "I am a sinner" uttered within a Christian sect. Both statements are important indications of reality as these people perceive it in their culture; both are integrated in their social life and can be understood in terms of the context. Being a parakeet in Bororo entails many norms for behavior and decision making in conflicts; the same applies to being a sinner.³

A clear difference with regard to philosophical systems lies in the fact that cultures are collective. A culture is something that the culture carriers have in common. Here, too, a certain graduation must be introduced, although with caution: features of the culture may be more or less common, but we must remember Geertz's admonition about independencies and crevices. More important, perhaps, is the possibility that the culture carriers may, within the group, have so much independence that we would have to speak of subcultures, part-cultures, and cultural minorities.

With the Baktamans, the integration does *not* take the form of a consistent whole of insights, information, or knowledge. On the contrary, people moving through the seven steps of initiation plus those who are uninitiated often hold mutually inconsistent units of information. At each step, things are asserted that are denied on at least one other step. This point seems to me to reveal an essential weakness in the conception of cultures as information units or other things akin to units of normative and descriptive knowledge.

Against this negative conclusion, however, we might object that there is no inconsistency at the step of initiation that is, within the culture, generally recognized as the highest one. At this step, the purpose of "misinforming" culture members on lower steps is also explained.

The objection does not hold, because the members who have essential misinformation are clearly also culture bearers. Their purported insights

are genuine parts of the culture. They are important parts of the total complex of conceptions about what it is right to do and to think, which constitutes the culture according to the intention- and information-oriented culture concepts.

The complexity that arises from the presence of conflicting information within different groups, however, need not prevent us from perceiving the Baktaman culture as, in some degree, perhaps a very high degree, integrated. It may be highly uniform, only not in the form of consistent insight or knowledge among the culture bearers. One might try to find knowledge concepts such that consistency does not belong to the necessary conditions. As far as I can see, however, no fruitful concept has emerged from such efforts.

Moreover, in cultures other than the Baktaman, one may also find contrary information where the maintenance of conflict is deeply tradition-dependent and protected by norms for what is right to do and think. Cultures cannot be comprehended as wholes of knowledge. Complex totalities, yes; totalities of a kind similar to knowledge no.

Within many cultures, certain groups are generally recognized as the most competent carriers, and their systems of insights may be consistent. This applies to the Baktamans. When we, in what follows, continue to compare philosophical systems and cultures generally, we shall, in the case of those similar to the Baktaman, keep in mind the conceptions of a subgroup. Those who are completely initiated define the unity and totality of a culture.

Message and Knowledge

In Western tradition, philosophies are mediated by texts. In other traditions, oral communication can be the decisive or only form. All systems presuppose at least some form of language.

How are cultures communicated? In linguistically accentuated theories of culture, *message* is a key word. The message does not have to be transmitted by words, but even if it conveyed without words, linguistic terms may be applied. A harsh look without words may have the same function as a verbal expression of disapproval. One can employ a nonverbal "vocabulary."

The sender-receiver relation is central: it must be taken as the normal case of a message that precisely what the sender *intends* to impart is picked up by the receiver. In cultural communication, however, the intention does not have to be conscious, as it must be for philosophical systems. For the present, I shall nevertheless stick to a concept of message that requires that conscious intention. This requires a person or at least beings that are capable of teaching each other something and eliciting or performing messages.

If a *unit of behavior* (with or without words) functions as a message presented by a person or group *A* and the receiver *B*, one may distinguish among three cases: the groups *A* and *B* are identical, they partly overlap, or they are entirely separate. The first case is conspicuously important if one is interested in comparing cultures with philosophical systems. *Cultural content must be constantly repeated among the culture bearers if the culture is to survive.* The new generation must learn much and thoroughly. If the transfer is inadequate, the content of the culture shrinks.

One may, in a linguistically oriented theory of culture, speak of what *is said* in a ritual. The apprentice learns something by seeing and performing a ritual. When the learning is complete, the learner has acquired cultural knowledge. The concept 'knowledge' that is thereby introduced is such that the anthropologist who employs the expression does not himself regard the content as knowledge, but, for example, as superstition. The content does not have to be cultural knowledge within the anthropologist's own culture. A ritual, then, is said to contain (as a whole and in its parts) behavior units that impart knowledge. The receivers, however, frequently differ widely in their competence to comprehend the message. This, of course, applies to philosophical systems as well.

During initiations, the apprentice is normally frenzied, and so much is new that only repetitions of the messages can lead to clear reception. A senior Baktaman says, "You know how it is during your initiation: your *fnik* (spirit, consciousness) does not hear, you are afraid, you do not understand. Who can remember the acts and the words?" (Barth 1975: 101).

The second part of Barth's book about the Baktamans deals with the seven degrees of initiation, from the first and lowest to the highest within the culture. His anthropological objective is as follows: "I wish to provide a substantive documentation of the forms of Baktaman ritual activity, and as far as possible establish not only what may be understood and intended by

the leaders of these cult activities, but also *what is actually received* as messages by audiences and participants" (Barth 1975: 47). If it succeeds, the procedure will ascertain "the nature and extent of the knowledge and insight" that is communicated by the seven successive initiations.

The goal set by Barth has important features in common with, but also important features distinct from, that of a university educator who wants to investigate what knowledge and insight is actually received, say, in an introduction to Kant's philosophy. One difference is that the educator may conceivably apply his own standard of knowledge and not Kant's. The anthropologist will evaluate the knowledge in relation to the culture that is to be "learned" through the initiation ceremonies.

As an example of messages without, or with entirely subordinate, verbal features, one might mention the torture involved in some of the initiation ceremonies among the Baktamans: "Water and fire are also used for torture, reinforcing the basic messages of earlier initiation: that these forces are powerful and dangerous; sacred knowledge is costly and must be paid for with hardship and its value thus confirmed" (Barth 1975: 66).

The study of Baktaman culture makes it clear that the many complicated ritual details are exceedingly important for both the learner's individual welfare and the culture's. Violations of the rules can cost the apprentice his life and cause disturbances in the whole society. Use of painful initiations emphasizes the gravity of the rules. Torture must presumably be counted as a much stronger way of communicating this knowledge than merely saying quite calmly, "Water and fire are powerful and dangerous forces."

It might be said that the comparison with such a sentence is unsatisfactory because the cultural message is so much stronger and more complex. We must, however, consider for *water* and *fire* in the above sentence words that in the Baktaman language give rich and complex associations.

The use of the words *knowledge* and *message* among linguistically oriented cultural anthropologists is close to the use that I as a metatheoretician of philosophical systems employ when I describe a specific system, or more exactly, when I seek to describe a specific system "from within," *in terms of its own premises*. The use of *knowledge* is in both cases subject to the axioms most commonly established for sentences of the class "*x* is a case of (an example of) knowledge."

Cultural Knowledge in Relation to Status

The use of the word *knowledge* in cultural anthropology is far from being unproblematic philosophically, as the preceding may have intimated. I shall now consider more closely a complication regarding the evaluation of Baktaman culture.

In relation to ritual and much else, there are eight status levels in Baktaman society. More than half of the members, namely women and children, are not initiated into the cult. Most others, on the other hand, go through a series of initiations. At the top status level is a small circle of men who have been through all seven steps.

A social structure with eight levels does not necessarily lead to a situation essentially different from the communication of philosophical systems if a new initiation only adds knowledge to that given at earlier initiations. Consistency would then be preserved. Consistency would also be preserved if the initiations made successively more precise an original content. The peculiar circumstance with the Baktamans, however, is that misinformation, hence simply (in part) false conceptions, is deliberately imparted on the lower levels. Only on the highest level is the complete truth revealed. The apprentices are systematically misled concerning particularly important and dangerous knowledge.

This presents a problem: do only the messages on the eighth and highest level express (cultural) knowledge? The messages on the various other levels are such that their conjunction is a contradiction. (I view efforts to make deep philosophy from contradiction as either failures or pointless attempts to introduce another terminology of little use.) If only the small minority that has been through all seven initiations has consistent knowledge, and Baktaman culture is defined in linguistic terms as the sum total of cultural knowledge, then most members of the Baktaman society lack Baktaman culture.

Such a conclusion is not drawn in Barth's presentation, and it would also go against well-worked-out points of view on culture in general. Barth uses the word *knowledge* in such a way that misleading messages also express knowledge. Another solution is to give up the linguistically oriented concept of culture, which seeks to construe culture as the *sum total* of cultural knowledge. Then a split must be made by saying that hypotheses and

norms on each of the eight levels belong to Baktaman culture, but that as a whole their eight-level system does not represent a unifiable totality of knowledge.

For the comparison with philosophical systems, this problem is not essential since it is natural to compare only the knowledge of the fully initiated minority with a system.

Description of Foreign Cultures and Untranslatability

The Swedish language may be translated almost directly into Norwegian in the sense that a Swedish sentence can usually be coordinated with a Norwegian sentence of about the same length and sense. The degree of similarity in content or sense can be tested without great difficulty because the Swedish and Norwegian ways of life and manner of thinking do not usually differ in confusing ways. It is quite another thing, however, to translate Chinese poetry or Vedic myths into Norwegian. The linguistic differences are more substantial; but much more problematic are the extensive and deep cultural differences. By employing suitable linguistic conventions on the vocabulary level, one can “translate” sentence by sentence, but anyone who has endeavored to study cultures knows that the meanings cannot be even approximately the same. One way of getting closer to the meaning is to append footnotes to almost every word in each sentence and, furthermore, to footnote each sentence as a whole. One explains, to the best of one’s ability, the proper senses of the words and the sentence. Even with classical Greek it is natural to proceed in this way. One conventionally translates *areté* as “virtue,” but then in a long footnote seeks to explain what the word signifies. The longer the footnote, the more it dawns on the reader that more than a slightly higher level of approximation cannot be reached.

A sentence in the Nuer language is conventionally translated to English as “Twins are birds.” Without a long footnote it is natural for the reader to ask whether the Nuers really think that this is true. Do they mean that twins fly or lay eggs? The footnote can provide the information to answer these questions, but can the “translator,” by means of footnotes (not foot-works), impart precise knowledge to the reader regarding the meaning that is intended when the sentence is spoken by the Nuers themselves? I think it is appropriate to use a concept ‘translation’ such that we can consider it a confirmed hypothesis that the Nuer sentence is untranslatable. This stance,

I believe, will be viewed as reasonable as soon as one gets an impression of the Nuers' way of life and manner of thinking — in short, their culture. It seems very different from English and Norwegian culture, so the burden of proof falls on those who maintain a hypothesis of translatability.

Anthropologists emphasize that when describing a culture one must take the culture's own terminology for one's point of departure. This is ambiguous. If one means the culture bearers' own words and sentences — in short, their own language — a sort of description results: the Baktamans' Baktaman responses to the researcher's questions formulated in the Baktaman language. This, however, is not what is meant ordinarily. One usually thinks of the concepts and what the foreign words mean. These must be the foreigner's cultural property; they should not be replaced by the anthropologist's, but it is highly problematic to imagine how this might occur if the cultural differences run deep.

If we say about a foreign culture that witchcraft is a central part of it, a reader from our culture will interpret the word *witchcraft* in terms of our own culture's understanding of it. Clearly, however, that interpretation will be colored by what we consider to be the essential characteristics of witchcraft. We will, as readers, seek precision in terms of our own culture's concepts. Anthropologists seek to avoid this kind of problem in various ways.

In his central work on the Azande, E. E. Evans-Pritchard (1937: 8) states that he does not strive "to define witchcraft, oracles, and magic as ideal types of thought," but wants to describe what Azande understand by *mangu*, *soroka*, and *ngua*. When someone explains *mangu* by saying that it is "a material substance in the bodies of certain persons," it is clear that distorted ideas are being generated. *Material substance* and other words in the explanation still give associations in terms of our, not Azande, culture. This can indeed be corrected, but the corrections become more and more copious. It becomes increasingly obvious that all aspects of the world picture are involved in all explanations. To clarify the meaning of one word, one ends up — and for practical reasons, indeed one has to end — with an enormous number of explanations. The verbal road to the goal is lost in the horizon.

If one does not end up with an enormous number of words, but reaches comprehension after a few steps, this is a sign that the cultural difference is not deep, such as the one between Swedish and Norwegian. It seems as if insufficient semantic analysis conceals the problematic character of pro-

ceeding from “the terminology of the foreign culture” and “describing the culture on its own premises.” In spite of the risk of dwelling too much on elementary semantics, I shall offer an example.

The cultural anthropologist learns about nearly countless *forms* of marriage. The power of words over thought is constantly shown by the fact that one thereby presumes to have a convenient point of departure for comparison of cultures. One culture organizes marriage like this, another like that. It is difficult to avoid the thought that there is one thing, one object, one relationship, *what we all call* marriage, that is common to all cultures but simply has different names and detailed features. If all marriage forms in all cultures are to be defined as subspecies and species of one and the same genus, however, then we must include only characteristics that are common. These are few and highly abstract. A selection of them may be included as conceptual characteristics.

In biology we have the concept ‘vertebrate’. All and only vertebrates have certain forms of vertebrae. This is straightforward for ordering some types of thought, but when we are dealing with similarities and differences between dogs, cats, human beings, salamanders, and eagles, the characteristic of having vertebrae has very little significance. The same applies to the marriage forms. “Marriage as such” exists just as little as “the vertebrate as such.” The existence of the two words, *marriage* and *vertebrate*, and the concepts introduced by making them more precise, does not secure comparability except on a very abstract level. On the level of way of living and form of life, hence on the cultural level, they are practically worthless. If one encounters angry dogs or an insulted married couple in some culture, it does little to remember that they are vertebrates or spouses.

Information of the kind “Their *marriages* are like ours except that they . . .” may have a limited value, but such constructions make deeper understanding difficult since one continues to keep a concept, or an association center, drawn “from home.”

It is more realistic to distinguish among a great number of relations in which human beings are involved. One must seek to describe them as far as possible in terms of a culture’s own premises (Barth); hence, without hanging them on familiar pegs. The latter expression is misleading since the frame of reference is and always will be the describer’s, not the one of those being described.

The relations in a culture infiltrate one another. Forms of marriage cannot be characterized except in relation to relationships between children and parents, between brother and sister, and hundreds of other relations. Differences in relations, hence in structure, determine differences in the experience of brotherhood, sisterhood, marriage, and all other *content*. Cultural politics seeks structures that affect attainment of the highest purposes of the culture.

In earlier chapters we mentioned differences between philosophical systems and the reduced comparability that results when their differences become deeper and wider. The same holds for differences between cultures. In addition to the catchwords in philosophies, a long series of other catchwords is added in the case of cultures. Instead of mentioning examples from various nonphilosophical realms, I shall mention catchwords from ethical aspects of the cultures and keep to the important words in Harald Høffding's once influential *Etik* (1926): authority, pleasure, displeasure, the individual, sympathy, welfare, motive of evaluation, motive of action, conscience, sanctions, duty, freedom of the will, external constraint, internal compulsion, ability, force, skill, autonomy, personality, evil, stupidity, callousness, purpose, means, society, altruism, justice, self-assertion, and devotion.

These words are taken from the beginning of the table of contents of Høffding's systematic exposition. The list serves as a reminder of the deep and general connections that exist among the individual phenomena or relations suggested by the words. If we extract one of them, say autonomy, it is clear that autonomy within one culture cannot be characterized thoroughly without going into all the phenomena suggested by the other catchwords. Isolation is possible only by more or less superficial and abstract consideration. We must use our ability to think in terms of *gestalts* in order to seek experience of the world of others.

The Depth of Cultural Differences

It is indeed clear that, construed as information, cultures impart different messages. If we compare cultures with philosophies, we can at once (with our own culture as a frame of reference) establish that two cultures may have different *ontologies*. The Baktamans are surrounded by spirits. The spir-

its are an important part of their world. Insofar as spirits are recognized as existing in our culture at all, they have another character than for the Baktamans, and if we compare the Baktamans with cultures in which spirits are also an important part of their world, we find different views of what spirits are. Closely connected with this issue are differences in *methodology* and *epistemology*, or more correctly, differences in how one establishes and perceives knowledge of spirits and other things. The rules and standards for governing conduct (*ethics*) and perception of history and time all vary — the same issues apply to social and political problems. In short, there are differences in all branches of philosophy.

It is not thereby claimed that all kinds of differences exist in all cultures. Lapland was no state but was nevertheless a rather “close” society in the sense elaborated by Nils Christie in his book *Hvor tett et samfunn?* (How tight the community?). The culture exhibited common basic political views, in the wide sense, but perhaps not a philosophy of state.

Furthermore, it must not be claimed that viewpoints within all the branches of philosophy are directly communicated in language or in other ways within all cultures. Some points of view emerge only on the meta-level, in the cultural anthropologist’s comparisons, not as parts of the cultures that are compared. With these reservations in mind, we can claim that differences between cultures may be deep and all-encompassing, just as deep and comprehensive as differences between philosophical systems.

The all-inclusive character of the differences between cultures owes in part to the fact that the differences concern fundamental positions such as those defined in philosophy and in part because cultures are more or less all-embracing and integrated. The latter has the consequence that differences at one deep point generate effects in all other areas. The culture as a whole is colored by the particularly deep-seated features, features that in terms of our classification system appear as profound and all-embracing.

If we compare Baktaman culture with our own, we see, for example, that the constant presence of the ancestors, and their constant praise and blame, emerges as a profound feature. I must emphasize that my use of *profound* here is meant in relation to a Norwegian frame of reference, not profound in any absolute sense. The presence of the ancestors is an ontological trait that describes the (“factual”) character of the world. The Baktamans are thus never alone; they are always supervised. The doctrine and experience of the ancestors cannot be described adequately in a few words. One

must consider each and every aspect of Baktaman daily life and specify in which way the ancestor factor comes in as a codeterminant.

If we compare Samoan culture with our own, property becomes a key word. "This is mine, that is yours" becomes a type of sentence that acquires another cognitive meaning, is involved in other structures, and gives another content of experience than in our culture. In the West Samoan village of Manase, the Dammann family could not "own" their provisions the way people can in Norway. Their supplies were theirs in a certain sense, but not in the way they would be in Norway. Illustrative of this difference is an episode from their first days in which a Samoan woman unabashedly inspects their belongings:

Speechless with insecurity because of all that we did not yet understand, we saw her examine minutely our stock of provisions from the village and not least a stack of dry-milk boxes that we had brought with us from the neighboring island. But when she then, abruptly and resolutely, grabbed half of the boxes and wandered out again, waving her hand, we finally awoke. Full of moral indignation, we ran after her to recapture our legitimate property. She was not going to get away with theft! But all our protest was in vain. When she saw our rage she herself became serious, pointed at us, at her own palm hut, at herself, and our storage shed, patted our shoulders, and walked away. What was it that she had wanted to tell us? (Dammann 1981: 24)

Within the groups of thirty to fifty related, intermarried, adopted, and cohabiting persons, there is "communal ownership, common responsibility and work" (Dammann 1981: 26). With such a six-word, abstract characterization, one gets an inkling of the difference, but no deeper understanding since indeed *community property*, *responsibility*, and *work* are catchwords that to us have a different meaning, are included in other structures, and give another content of experience.

It is easy to emphasize that the differences in question here are universal, that they affect all relationships. More, however, is required for characterizing them as deep. It must then involve great difficulty to adapt to the foreign culture. The difficulties may be divided roughly among two dimensions as purely cognitive, purely affective, and combined affective and cognitive, depending on the experience one has in attempts at adaptation. Property is affectively loaded when the situation is of the kind exemplified above. It is presumably affectively very hard for us to adapt to communal ownership and common responsibility. Besides, it requires that things be per-

ceived in other ways. The cognitive difficulties are considerable but there is also the normative dimension: theft is wrong, morally reprehensible.

To what extent can the depth of the differences be isolated from the scope? The question is too vague for a precise answer, but a couple of examples may help to illustrate how a deep difference can be of a relatively modest scope.

If, in Manase, one points to something in someone else's home and expresses that one likes it, one receives it as a gift. The decisive feature with respect to the depth of difference from Norwegian society lies in the enormity of what one can then receive (and according to the norms should not refuse):

A little girl whose name was Norin (Nolini in Samoan) aroused the enthusiasm of the whole family. She was nine months old, had large eyes, was golden brown and lovely. Every day her mother came and placed her in our *fale* so that Jaran could play with her. One day when she was delivered, Ragnhild said jokingly, "Norin is so delightful that I think I must take her along to Norway!"

Of course she should not have said that. The next day the mother came with little Norin, her cheeks shining of coconut oil, adorned with dress and flower in her downy hair: "Please! We have talked about what you said yesterday. Now she is yours."

Good heavens, what had we done? Stammering in a desperate attempt not to offend the giver of this unbelievable gift, we eventually managed to explain that even if there was nothing we would rather do than keep her, we could not take Norin from Manase where she was so comfortable, to Norway's cold climate, which she would perhaps not endure. . . . (Dammann 1981: 27)

The episode is copiously rendered so as to make concrete the difficulties in adapting to a deeply different culture. These are such that one must comprehensively and profoundly change oneself—albeit, as a cultural anthropologist, only temporarily—if it can be done.

Cultural anthropologists sometimes write in a way that many readers misunderstand. The readers get the impression that the anthropologists pretend to be able to *understand* many widely different cultures, while at the same time maintaining their own cultural identity. What is pretended, presumably most often, concerns a limited number of schematic cultural structures rather than cultural contents.

Most likely, one's perspective on anthropology must change when one acquires an intimate understanding of a culture that is profoundly different from one's own. It is difficult to understand how an anthropologist could be

able to walk in and out as an ordinary tourist and hence keep one and the same frame of reference for his own field, so that after a dip in ten different cultures he or she could compare them within the old framework. Even a talented actor may have difficulties keeping the same perspective after performing in different dramas.

Back to Manase. Since gift situations of the kind exemplified can to some extent be isolated, the difference does not necessarily involve the culture as a whole. It is deep, but not all-pervasive. Consider an example of depth, but without maximal scope—also from Manase:

The children's importance as helpers in work is also connected with an interesting Samoan tradition.

If the exploitation of the children's working capacity goes too far, they can move to another palm hut and simply choose a new pair of parents as their closest guardians. And because the children's work contributes to the provision of food as well as diminishing the workload of the adults, they will always be welcomed with delight.

What, then, if the original parents refuse to accept the child's change of residence and come to fetch the child? Then the new parents will refer to *fa'a-Samoa*, the old Samoan customs that give the child the right to make up its own mind about where it will live. The parents will be turned away even if they have the highest chieftain-titles in the village.

This right gives the children protection, also against brutality, neglect, and injustice. In a society where the borders between the families are as diffuse as in Samoa, it is not a difficult breakup for a child to move to an uncle or aunt in the same *aiga*. (Ibid., p. 128)

If we concentrate on the right of a child to choose with whom it will live, this can to some degree be isolated as a deep difference that does not penetrate all life's conditions. This trait, however, is intimately connected with something all-pervasive about the family structure: everyone within an *aiga* has such close relationships that they border on family relations. Thereby the concept pair 'home/dwelling' is also affected. Furthermore, the work concept is affected. The parents have a right to require the children to participate in work, but otherwise they meddle very little. In Norwegian society, adults and children seldom work together, and the demands on children rise with full force outside of work.

Within cultural anthropological and philosophical literature there is today (the third quarter of the twentieth century) not much discussion of

how one could systematically compare depths of the kind addressed here. It is, therefore, worth the trouble to seek somewhat greater clarity.

Let us say that we want to know how profoundly our conceptions are compared to those we (purport to) encounter in Spinoza's *Ethics*. In the *Ethics*, part 3, note to theorem 11 (IIP11S), Spinoza says that joy (*laetitia*) is a feeling (*passio*) whereby the mind (*mens*) increases its perfection (*perfectio*). This conception of joy is explicitly used as a premise in twenty-three later proofs in the *Ethics* and in two explications (*explicatio*). If another system builder differs in his interpretation of *joy*, *mind*, *increase*, and *perfection* as these terms must be comprehended in the note about joy, then all twenty-three proofs and the two explications become the focus of attention. The possibility exists that the divergence in interpreting IIP11S has as a consequence hundreds of other differences in understanding. The disagreement in interpreting IIP11S is thereby a symptom of a relatively deep difference between the two systems.

If, on the other hand, the disagreement concerns Spinoza's definition of the essence of benevolence, the disagreement is likely to have few consequences, because benevolence affects very few elements in the *Ethics*. There is no basis for the assumption that the divergence is deep-seated.

Hence, we may take the position that the differences within the chains of justification represent an index for the depth of difference between two systems. If *A* is justified by *B* (and not *B* by *A*), then to say that a difference in standpoint *B* lies *deeper* than a difference in standpoint *A* means that: the difference yields *greater* consequences as more of the system is justified by means of *B*. The index is of interest even if the exact order of the links in the chains within a system that is well worked out logically is to some extent arbitrary.

According to part 1, theorem 14 (IP14), there can be only one substance (*substantia*), namely God (*Deus*). Only three other elements in the *Ethics* depend *explicitly* on this theorem. One of these elements is the proof of IP15, that whatever is, is in God, and that nothing can be or be conceived except by God. Implicitly, IP14 is used in substantial parts of the system insofar as a disagreement — such as Descartes's claim that there are two substances — would decimate much if the proposition were to be included in Spinoza's system. Some would say that including Descartes's claim would destroy everything. I will return to this thought, but for the time being let us assume that the theorem about joy could still stand.

A closer comparison of Descartes's doctrine of two substances with Spinoza's doctrine of one substance must, I believe, result in the conclusion that the difference is deep, although not necessarily abysmal.

The all-pervasive characteristics of a culture exclude isolation of economy, religion, and so on as parts of a culture that can be understood by themselves. The untenability of such a division is clear from other points of view as well. Consider Gregory Bateson's statement (1972: 64) that "Our categories 'religious', 'economic', etc. are not *real* subdivisions which are present in the cultures which we study, but are merely *abstractions* which we make for our own convenience when we want to describe cultures in words." Something similar applies to philosophical systems. The untenability is most noticeable when solutions to special problems are compared, such as solutions to "the free-will problem" within different philosophies. There is no precise problem that is common, because the conceptual words *free will* and *liberum arbitrium* stand in different relations within essentially different systems. The subject divisions in ontology, epistemology, methodology, and so on are expedient for our own surveys (which, of course, are part of our own system).

We are likely to find that, superficially seen, cultural differences and differences in philosophical systems have little to do with each other. This is because one *lives* in cultures, but not in philosophies. One has difficulties in adapting to cultural differences, but questions about adaptation do not arise in philosophies, presumably.

Since philosophical systems that are not fragmentary contain ethics and the many parts of social philosophy, they comprise philosophy of life and philosophy of culture—but they must not be confused with encyclopedias. They do not go into the details. The difference, however, is more formal than real in regard to comparison with cultures, for if it is not presupposed in the development of a philosophy that it is to be fit for use in practice, and hence in concrete life situations, then it becomes pointless.

Let us say that two norms in a radically simplified philosophy can be expressed by "Be honest!" and "Be friendly!" In practice, countless norm conflicts ("collisions of duties") arise. They may, as they arise, be solved in various ways. One can even, by constant modification of the definitions of *honest* and *friendly*, claim that conflicts cannot arise. The abstract, general norms "Be honest!" and "Be friendly!" lose meaning if they are not conceived to be applied in concrete life situations. Indeed, it is only through a

concrete context that a person can be judged as honest — or can be anything at all. Ask Søren Kierkegaard!

Thus, in a philosophy with abstract, general norms and hypotheses, it must be assumed that they acquire meaning in concrete life situations. Even if they do not say anything concretely about this, it must be assumed that given a concrete (singular) situation, philosophy *A* will provide guidance for a behavior that is either similar to or different from the guidance offered by philosophy *B*. Thus, the question arises, To what extent is it possible for one whose life is influenced by philosophy *A* to adapt to philosophy *B*? Moreover, in the case of philosophies, it becomes relevant to speak of more or less deep differences with respect to the kind of life that is led in terms of them.

I have up to this point dealt with the depth dimension without relating it to the question of whether comparison is possible at all. Is comparison possible except in terms of a grossly simplified semantics?

Within systems, some words and expressions are defined and others are not. Definitions often form chains: *A* is defined by *B*, *B* by *C*, and so on. Often a comparison depends on the occurrence of one and the same word, which is uncritically assumed to mean the same thing in the two systems. If it becomes clear or at least reasonable to assume — by the study of definitions or in other ways — that the word has different senses, the performed comparison with respect to subject, agreement, and validity no longer applies.

A concept 'semantic depth' with respect to a difference may be introduced by taking account of how deep-seated the difference is in the chains of definitions and the directions of precization. With sufficient depth, comparison disappears more and more.

If we then turn to a consideration of cultures as they are systematically represented in terms of the information model or Barth's model, analogous relations between deep and less deep differences may be drawn. Clearly, in the case of the Baktamans, the norms for the eight population groups' relations in ritual matters affect all aspects of their life. The norms are deep. The Baktaman world picture is influenced by them and by the ontology presupposed for the norms to make sense. A culture that has none of these norms, and of course there are many such cultures, will *as a whole* be different. The deep point-by-point differences in relation to ritual conditions

yield differences at all other points. We have no common basis for comparison. It is like looking for absolute time in physics.

Misinformation and secrecy among the Baktamans complicate the picture, since they appear to cause a general uncertainty about what is right and true.

The observance of taboo and secrecy thus takes on a new meaning, together with a restructuring of categories of purity and pollution. But this is not without profound epistemological consequences: deceit is not just an expression of opportunistic self-interest, or the supremacy and whim of senior men. It is shown to be a means to generate deeper truth. And some time, the question seems inevitably to arise: where does this end? Are there not secrets withheld in the 5th degree revelations, that create deeper knowledge for others by virtue of being withheld from me? And what about 6th, and 7th degree? Pursuit of true knowledge becomes like peeling the layers of an onion, or exploring a set of Chinese boxes: information on one level may be the deceitful cover that creates another kind of truth at a deeper level. How and when such doubts set in is hard to tell; but their eventual presence can be demonstrated. . . .

(Barth 1975: 82)

Such a strange and profound uncertainty about the innermost essence of reality is clearly a peculiarity likely to cause deep cultural differences. The same applies to the peculiar relationship between the sexes among the Baktamans, a relationship characterized by little trust. In view of the difference from our own culture, neither the concept of 'security' nor the concept of 'sex' can be taken as a point of departure for precise comparison. It is no use to reply that indeed Baktamans, Scandinavians, and all others eat, drink, and sleep and that we therefore have a lot in common. We are now concerned with how world and reality are perceived and felt.

Profound differences must be supposed to characterize the differences in *experience* of reality. The carriers of one culture can easily be imagined to be able to *suspect in which direction* the differences lie between their own culture and their experience of another culture. From this imagination to the point of actually experiencing the other culture, however, is a great leap. Is it possible at all? If it is possible, how can it be expressed?

The analogy between philosophical systems and cultures is clear: it seems possible to indicate both isolated differences and the direction in which deep differences influence entire systems, but to experience the

world in terms of different systems is another matter. It is natural here to emphasize the difference between knowledge of structure and experience. There does not seem to be any definite limit to how far one can mine the area of structural knowledge about differences, but in doing so not much is said about how far one can apprehend things in relation to experience. Structural knowledge will perhaps some time in the future be left to unfeeling robots. The question "How does the world appear to N. N.?" cannot be answered by abstract indications of structure, but perhaps it also cannot be answered by trying to *show* the world as it appears to N. N.

These sceptical statements should not be accepted without certain qualifications. They must be viewed in terms of questions—questions of degree, not absolutes. Even within a culture, indeed even within a family, there are similar limitations to insight into how the world appears "to the others," how it is concretely experienced. Here, however, we have some building blocks and elements. We can say, for example, that for my brother certain things are more threatening than for me, and we can indicate what those things are and train ourselves to perceive them as threatening. It is more difficult to take account of different second order attitudes—differences in reaction to the consciousness of being threatened. These color the very experience of threat, of course. Point by point, we must assume that we can experience the world in the same way as the others—but do these "points" really exist? When we are concerned with deep cultural differences, the distance from genuinely experiencing the other's world can be essentially much larger. The problems are not fundamentally different.

It is not unusual for people to say that this or that person or nation lives in another reality. For them, multiple realities exist. The terminology I employ distinguishes between *world* and *reality*. The expressions just mentioned will, in the terminology of this book, be rendered by saying that the person or nation lives "in another world." By "reality" I understand something that I cannot conceive to permit plural "realities." The most different cultures are all within one reality, and it is this that they seek to comprehend.

The Absolutization of One's Own World Picture

The absolutization of one's own cultural content ordinarily takes natural and innocent forms in cultural anthropology. Northwest Greenland, for ex-

ample, is the most hostile milieu human beings have ever lived in, according to Fred Bruemmer (1981: 43), but the Polar Eskimos did not *think* of it as especially hostile and called it Nunassiaq (the beautiful country). In the introduction to his work on the Azande, Evans-Pritchard (1937: 20) says that he wants to examine ideas which “though they do not accord with reality, are yet of supreme importance both to Azande and to Europeans resident among them.” He cautions his readers, however, against believing that the Azande, in addition to expressing mystical thoughts, cannot also express themselves commonsensically and act empirically. They are not in such a bad way as one might think.

The world that Evans-Pritchard refers to simply as reality, can, we presume, hardly be distinguished from the reality he himself has been brought up and trained to understand. His ideas about the opposition between mystical and commonsensical thought and between ritual and empirical action would hardly be accepted in a cultural anthropology prepared by the Azande in Azande country.

Consider another and perhaps more controversial example: Keesing (1976: 142) suggests that one reason why we do not abolish discussions of cultures is that we are inclined to strip meaning from what we call physical reality. He asks why we must talk about this shadowy hypothetical entity ‘culture’ that we can by definition never observe or document? Why can’t one simply investigate actions and events in a social system without invoking a metaphysical entity such as culture?

Keesing maintains that we must invoke such “metaphysical” entities because, for example, we cannot understand behavior without assuming that it has meaning. We cannot *measure* the difference between a wink and a twitch in the face. He suggests that much of what we perceive in the world, and dress up with meaning, is not in the physical world at all (Keesing 1976: 142). The existence of a physical world without meaning has been a feature of European cultures since the fifteenth century. In Keesing’s remarks we also find hints of a methodology and theory of concepts that are not completely intercultural or culturally neutral. These remarks, however, cannot as a matter of course be taken as criticism. We are now in the midst of the problems of system comparisons.

If one requires that the cultural anthropologist compare cultures without using his own culture as an absolute reference, then we automatically enter the problem cluster concerning “the third system”: a kind of superan-

thropology that permits one to survey the multiplicity of cultures without oneself taking a position on any one of them, indeed without being locked up in their terminology and conceptual structures.

How, then, is the cultural anthropologist to proceed? In his short paper, Barth (1977) mentions essential points about “the method,” the way to proceed. An essential step is to avoid the ethnocentric point of departure and see all cultures, including our own, from the same comparative viewpoint. As a cultural anthropologist, one’s perspective must be so broad that it acknowledges and respects the agent’s own premises as well as the researcher’s, so that each culture can be understood as a world alternative to our own.

These sentences open up enormous philosophical problems, but here I shall limit myself to a short comment. Let us designate the cultural anthropologist’s culture by A and the series of n cultures he or she describes in research by B_1, B_2, \dots, B_n . The anthropologist could presumably then be said to perform a series of descriptions (b_j): $b_1(AB_1), b_2(AB_1), \dots, b_n(AB_n)$.

For example, in terms of A (her own culture), the anthropologist notes: “Her uncle enters by the door and greets.” In terms of the agent’s own premises and world picture, however, it is no uncle in A ’s sense who enters, nor any door in A ’s sense, nor even any greeting. What then actually occurs in the world designated as B_1 ? That can only be discovered little by little (insofar as it is accessible in terms of A) through thorough and prolonged “participant” observation. Each of the descriptions $b_1(AB_1), \dots, b_n(AB_n)$, then, will gradually change in reference to the B_1 component. These changes in description, however, will have to be formulated directly (by use of *and*, *or*, and so on) or indirectly (by definitions and other rules of use for *uncle*, and so on) in A ’s language. In short, the descriptions, b_1, \dots, b_n , are registrations of life in all the cultures observed by A, B_1, \dots, B_n , in A ’s language.

One question that arises immediately is whether all cultural anthropologists must belong to one and the same culture, for example Fredrik Barth’s. If each culture can in principle produce anthropologists as genuine members of the culture, then we may envisage a multitude of registrations $b_{ij}(B_i B_j)$ written in the language of each culture. If not all cultures can produce anthropologists, then questions arise about the “fundamentality” of the cultures as well as about the intercultural status of science — to put it

somewhat abstractly for the present. This comment is only meant as a philosophical aperitif.

Back to the method, however; since the cultural anthropologist must, at least at the beginning of his studies, be presumed to be a member of some culture, he or she employs a frame of interpretation characteristic of that culture. To this frame of interpretation belong special culture-specific concepts, points of view, rules, and patterns of behavior. This at least seems to be the situation, judging from Barth's statements (1977). He writes that social anthropologists must seek, in the manner of researchers, to define their own frame of interpretation for the global cultural variation in terms of the character of the data, and preferably try to develop it (or "transcend" it) to attain a deeper understanding of reality.

The term *define* here is presumably very close to *delimit*. One must become aware of one's own provinciality incrementally — to say something in another way. The more one attains insight about a multitude of other cultures, the more exactly and deeply one can articulate the characteristics of one's own culture. Thereby, one's own culture can be "transcended" in a certain sense, but exactly which one? Does one break away from one's own culture? Does one find a more and more universal frame of interpretation?

The latter might conceivably involve anthropologists from the cultures B_1, \dots, B_n bringing forth a common language that becomes comprehensible only after study of global cultural variation. All the descriptions of the cultural anthropologists would then in principle be directly comparable, and they might even correspond.

These possibilities, however, raise enormous questions, such as those in ideology research that have been taken up by Gerrit Huizer and Bruce Mannheim (1979) and others. Can the researcher manage to stand outside each single culture? Must the researcher create his own type of culture, which has the special characteristic of being capable of acknowledging and respecting all cultures in terms of its agent's premises? This amounts to a requirement that each culture must be understood in terms of its own pre-suppositions.

It is natural in terms of a priori philosophy to reason as follows: There are demonstrable limits to the differences between cultures. In order for something to be understandable as human culture, the members must *think*, but there are universally valid laws of thought, such as the principle of contradiction. If these laws are violated, we cannot acknowledge that

thinking is present. Hence, by virtue of classifying something as a culture, we will already have claimed implicitly that the members intend to follow the same laws of thought as we do. They will thereby also have to presuppose the same concept of truth. The members of a culture, including our own, may fall into self-contradictions, and deviants may *claim* to have another concept of truth. Nevertheless, that does not affect the core of the matter: cultural differences do not penetrate so deeply that they affect logic and truth-concepts.

This view may be said to absolutize logic and truth-concepts, and insofar as one maintains that these topics are unique to our own culture and unavailable to those that are still often called primitive, it involves an absolutization of one's own culture. A very clear defense of this view is delivered by Steven Lukes:

It follows that if *S* [some assumed culture] has a language, it must, minimally, possess criteria of truth (as correspondence to reality) and logic, which we share with it and which simply *are* criteria of rationality. . . . But if the members of *S* really did not have our criteria of truth and logic, we would have no grounds for attributing to them language, thought or beliefs and would *a fortiori* be unable to make any statements about these. (Lukes 1970: 210)

This standpoint may well seem reasonable to all except two groups: (1) those who hold with Lévy-Bruhl that "the primitive" reveal "prelogical" thought, and violate the principle of contradiction, but may nevertheless be subjected to detailed cultural anthropology, and (2) those in our culture who are specialists in logic or the problems of truth-concepts.

The latter group is the most interesting from the viewpoint of this book. Just as one can distinguish between purely formal geometry, which does not say anything about points and lines, and physical geometry, which does, one may distinguish between purely formal logic, which does not say anything about whether something is logical or not, and natural logic, which does. Natural logic is not independent from what is supposedly meant when it is said that something represents "rational" thought. There are a great number of different formal logical systems, and much debate concerning which ones are most fitting as natural logics. Moreover, even among these logical systems, there are often many versions. This pluralism can be understood in different ways. The simplest one for me is to empha-

size that when we say that a set of thoughts does not violate the principle of contradiction, the depth of intention is not infinite—very different precisizations may seem meaningful. Hence, we have no grounds for postulating that there *must* be one and only one universally valid logic, although we must then add that this does not imply that they all contradict each other. On the contrary, great difficulties in principle militate against proving or disproving contradiction among logics.

In the matter of truth-concepts, the debate is just as open. Pluralism seems to me the most reasonable conclusion, but it is not accepted by all specialists.

We can conclude from this that logic and truth-concepts do not represent unique, fixed structures that constrain cultural difference and pluralism. Euro-American cultural anthropology does not presuppose one entirely definite logic and one completely determined concept of truth. Furthermore, even if it did, that would not imply that cultural anthropologists in other cultures must have the same logic and the same truth concept. There do not seem to be any a priori limitations to the differences, but neither can it be excluded that future research will not find it reasonable to assume certain specific limits.

In view of this, there is scant basis for singling out our culture's rationality, logic, or truth concept as universally valid. Such an absolutization is not justified.

The philosophical problems in the border regions of cultural anthropology are perhaps not as multifarious as may appear from the preceding. For it may be that anthropology in the first place, primarily or as a minimum, seeks to investigate *the structure of cultures* rather than their content. One lives in a house, not in the structure of the house. Now one might object that the more one counts as part of the structure, the more essential an understanding of the structure becomes for the understanding of the house. This may be the fate of "structuralism": one seeks to include so much in structure that one fails, as a researcher, to describe the content adequately. The philosophical questions concealed here are very old and are most frequently discussed within the form/content terminology.

Whatever one means about the relationship between structure and content, it is clear that cultural anthropology has enormous and fruitful tasks in the matter of clarifying and comparing structures. This corre-

sponds to comparison of the structures of philosophical systems, such as the *in se/in alio* conceptual structures from Aristotle to Leibniz; autotelic/heterotelic value in the theory of values; and induction/deduction in methodology. The more studies of structure dominate, however, the more cultural anthropology will perhaps turn into (general) sociology, or it will become an explanatory science that those who live in a culture cannot recognize as a description of their own experienced world (see Claude Lévi-Strauss's research program).

By concentrating on abstract structures, researchers may perhaps make fundamentally different cultures comparable. The "small society of Bushmen in the Kalahari" and the "metropolis of London" have, for example, some linguistic structures in common — at least more in common than the most dissimilar languages known to date. The common structures at this abstract level are, of course, not known to the ordinary members of the different cultures. One of our problems is the cultural adherence of the comparative cultural anthropologist.

Like a philosopher working with his system, the members of a culture change it themselves. Like philosophies, cultures constantly reveal influence from outside. All cultures seem to be constantly changing; and most cultures are, in spite of their differences, dependent on others. This also applies to philosophies, which are in part developed in conscious opposition to others.

Each philosophical system and each culture construed as an all-inclusive system of meanings seeks to articulate reality itself. One finds as part of any developed system a doctrine of other systems. They are at first degraded to world pictures, but then it dawns on us that indeed our own system can provide only one world picture among the many. Which world picture, then, is the one that gives a correct representation of reality? There does not seem to be a possible answer to this question. We cannot step out of our own skin. Since the individual systems do not confine themselves simply to forming pictures, but rather attempt to give a direct expression of reality, the question can also be put thus: which world is the real world?

It should emerge from the preceding that the question cannot be made more precise beyond a certain limit. Among the not very precise answers that can be given, however, I find the following: any world is real that gives an all-inclusive content of meaning; the others suffer from the unreality of the fragment.

What Kinds of Cultures Can Develop a Cultural Anthropology and How Different Can These Anthropologies Be?

As soon as a culture has contact with one or more others, attention is (unavoidably?) drawn to differences in accepted practice. This is when the beginnings of cultural anthropology emerge. The culture carriers in Azande country make expeditions to other countries to fetch oracle poison. A man who reaches the Bomokandi River is aware of differences in customs, says Evans-Pritchard (1937: 277). Quite a number of people have reached the river, obtained poison, and brought it back wrapped in *nghongborongba* leaves. This contact with other cultures has changed the Azande's own culture. Their conceptions about "the others" form the rudiments of a cultural anthropology.

One way of generating greater clarity regarding the absolutization of one's own cultural background is to try to imagine how a cultural anthropology might look within cultures that at least apparently do not have, and have not had, such a cultural product. As for the Baktamans, they have been so isolated that they have had only a few external contacts, and these have been almost exclusively limited to people with similar cultures, for example, the Seltamans. In recent years, the Baktamans' contacts with industrial cultures have increased, and their basis for developing conceptions of these cultures has expanded in step. Fredrik Barth himself has contributed to this situation. It seems clear to me that the nascent "Baktaman cultural anthropology" will differ deeply from our own, so deeply that some researchers may refuse to employ the designation. Here differences in philosophy of science are at play.

At the turn of the century, Euro-American cultural anthropology was so filled with cultural arrogance that the promoters of science hardly imagined the possibility of another form of cultural anthropology than their own. Now comparative history of science is an established field, although it tends to concentrate on a few Eastern and Western cultural traditions—Chinese, Indian, classical Greek. A pluralistic, or even possibilistic, view of research and conceptual structures in general, opens up the way to a relativization, or rather a relational view, of the conception of deeply different cultural anthropologies as parts of deeply different cultures.

Presumably, strong expostulations against approaches at variance with occidental anthropology manifest themselves even today, especially among

CULTURES CONSTRUED AS ALL-EMBRACING SYSTEMS

those who still speak of simple and “primitive” cultures. To be “primitive,” says Bryan Wilson (1970: xviii), a sociologist solidly acquainted with anthropology, is to stop being an anthropologist, “since anthropology operates according to norms and values that do not inhere in primitive society.” Many traditional societies, however, have more or less lively dealings with others, and there are therefore also traditional forms of doctrine about “the others.”

The strong position of cultural anthropology today in the industrial societies perhaps results from the fact that we maintain the dominating distinction between nature as meaningless raw material and culture as human projections of meaning into the meaningless. More uniform conceptions of nature, man, and world undermine the potential for a kind of isolatable science of cultures.

VI

Some Conclusions

In the preceding chapters, I have tried to answer some relatively precisely posed questions with relatively precisely formulated answers. However, the questions (“Which world is the real world?” and so on) with which the investigation began are themselves not precise — they are vague and ambiguous. They are compelling because they are engaging, disturbing, universal, and demanding of answers. The relatively precise answers emerge by more or less arbitrary choice of certain special lines of precization and concept creation (for example, ‘system’). Therefore, they do not cover the questions in their natural wealth of meaning. The question arises, Could I offer brief answer formulations that cover the questions without introducing so much vagueness and ambiguity? What follows are attempts at such answer formulations. In keeping with the goal, the style is simple and dogmatic.

Most of the individual, numbered conclusions are divided into two parts: where there are entries, the first one concerns philosophies; the second, cultures.

- 1a. Is it possible to say something about everything, as a few great philosophers seemingly have tried to do? Yes, one must, however, add some technically philosophical, limiting precizations of the word *everything*. This is necessary to avoid certain logical paradoxes. We must avoid letting *everything* stand for *absolutely* everything and precize in the direction of “all *types* of things, collectively.”
- 1b. Is it possible for a culture to cover everything? Yes, if reservations similar to those described for systems are allowed.
- 2a. Is there any value in seeking to formulate such an all-inclusive system or to familiarize oneself with those that already exist? Yes. A person with his sensibility intact has a way of perceiving the world,

SOME CONCLUSIONS

himself, and “everything” that is viewed as related. It is valuable to obtain some degree of awareness of this total view. Our attempts at system formulation are often reassessed when we are confronted with deeply different philosophies. For the significant number of people with an intense need for conceptually articulated total views, it is necessary to go on working with existing system attempts as points of departure.

At this juncture, too, one must add caveats and make precisizations so that absolutism is avoided. However deep the sensitivity and however intense the search for both totality and consistency, one has to account for the likelihood that some things will be fragmentary, inconsistent, and changeable over time.

- 2b. In most cultures, it is regarded as valuable to nurture an awareness of one's own culture, in part for reasons that have to do with internal oppositions and other relationships, and in part to facilitate the resolution of confrontations with other cultures. A picture of one's own culture strengthens its traditions, increases respect, and provides guidelines for changes. Just like the culture itself, the picture of it tends toward totality and completeness. Articulation of these pictures results in total views of the types classified by Jaspers.

It is doubtful that the preceding rather general and abstract statements about cultures can be made appreciably more precise without losing meaning or becoming inconsistent.

As with contradictory philosophies, cultures will contain conflicting norms insofar as deviants from a standard are characterized by an inconsistent totality. The “criminal” and the “countercultures” within a culture belong to the culture.

- 3a. Can a philosophy in a meaningful way purport to be true and binding for anyone, at any time? Yes. It is not necessary to accept a relativism with respect to validity. The statements “All standpoints are historically conditioned” and “All fundamental propositions in a conceptually articulated view of life are subjective” are examples of meaningful system statements that for certain plausible interpretations are intended to be true for any subject at any time, regardless of the historical period.
- 3b. If a verbalized, systematized direct expression of a culture contains statements about the relativity of cultural values, these statements

are to be considered as genuine partial expressions of the culture. The same applies to appended statements to the effect that the statements about the relativity of cultural values themselves have culture-relative validity. The last link in such a chain of meta-metameta- . . . statements, which represents a direct partial expression of the culture, is nonrelativized and without reservation.

This point of view is controversial. If we assume that we can step out of our culture and *consistently* see it from the outside, we delve into theories that address the possibility of culturelessness; these are not to be discussed here.

- 4a. Insofar as a system characterizes itself as one all-inclusive system among many possible ones, relativism is admitted. The pretension of being the only true system cannot be taken as absolute. The original characterization of the system can be made precise only in terms of its own conceptual net; thereby an inconsistency arises. The solution lies in moderating the pretension that “everything” is encompassed (see point 1). Attempting to sketch cultural anthropologies within the conceptual frameworks of other philosophies, thereby admitting the relative validity of the system, also leads to inconsistency. The absolute pretension of the system must be moderated, but it can pretend to be “nearly” total, which can be made precise by the relation “more comprehensive than.” This relation replaces the predicate “all-inclusive.”
- 4b. A cultural anthropology may, at the outset, state that the description of all other cultures occurs in terms of the conceptual framework of one all-inclusive system.
- 5a. Are there all-inclusive systems? Yes, those of Aristotle, Aquinas, Spinoza, Hegel, and others. By virtue of forming a sentence with the pretension of articulating something conceptually adequate in the form of a proposition, we have already pretended to have a system. Conceptually adequate articulation requires logic, methodology, and other disciplines that in our time, as in a thousand years past, dominate the system formation. These disciplines, however, can no longer be expounded and justified in isolation from other types of problems.
- 5b. A culture, as defined in this work (see chap. 5, pp. 106–16), in contrast to philosophies, is all-inclusive. It must be emphasized, how-

SOME CONCLUSIONS

ever, that cultures are constantly changing and that they cannot be “carried” by any single individual.

6. Are the five formulations that are implicitly asserted by the preceding “yes” answers true for all plausible interpretations? No.
7. Are there limits to the formulations’ precizability, to the depth of intention, and to the fine-meshedness of the net of discrimination? Yes. They have validity and adequate meaning only to some extent. There are, however, also limits to the specifiability of the limits.
- 8a. Can an (approximately) total system be expounded in a manner that is exactly and entirely comprehensible to the outsider? No.
- 8b. In the case of cultures, the limitation in both the exactness of the descriptions and the depth of the understanding appears more distinctly. No single concrete thing or event is the same in two deeply different cultures. Culture *A* is, to begin with, expounded in *B* in terms of *B*’s framework; culture *B* is expounded in *A* in terms of *A*’s framework. Constant improvement of descriptions is likely to improve and further refine understanding, but still only within limits.
- 9a. Can one give a continuously more exact and comprehensible exposition? No. Understanding seems to have to be developed discontinuously, stepwise, precisely at the most decisive dividing lines.
- 9b. Point 9 is more obvious in the case of cultures.
- 10a. Can a total system be improved? Yes, but only by internal changes, in terms of the goals and standards given by the system.
- 10b. The term *improvement* is not so apt in reference to cultures. A culture has internal oppositions and inconsistencies that constantly challenge efforts aimed at richer and more consistent development.
- 11a. Can a total system be open like a science? Yes, but the openness of the sciences also has limitations in principle.
- 11b. The openness of a culture is obvious, but where is the borderline between further development of one culture and transition to another one? Even with a very wide border area, the answers will seem rather arbitrary, even if we seek to relate them to particular, tolerably precise concepts of ‘culture’.
- 12a. Do all total systems refer to one and the same reality (in a wide sense)? Yes. Any philosophy aims to discover reality through what it states. To assume that different philosophies speak of different realities

will not help us understand the differences in what they assert. It is better to say that the pictures they provide are different. The world pictures differ and none of the worlds as pictured can be identified with reality.

- 12b. A culture (in the form of norms and descriptions) has the same kind of relation to reality while simultaneously delimiting a “world lived in”—an experienced world and a way of living.
- 13a. Can two systems be compared exactly and intelligibly for an outsider? No. The greater the exactness and genuineness of the representation, the smaller the degree of comparability. This follows from point 8.
- 13b. The same applies to cultures.
- 14a. Do systems fall within fixed categories, and can the range of variation be exactly indicated? No. The more exactly a categorization (classification) is performed, the closer a typology of systems comes to being part of a particular system.
- 14b. The same applies to cultures.
- 15a. Similarity and difference in the *structures* of systems must not be confused with similarity and difference in *content*. The content must ultimately be precized as experienced content. An exposition of a philosophy conveys how reality is as it is experienced through that particular philosophy.
- 15b. Cultural anthropology as a science needs testable statements, and these must exclusively or predominantly refer to structures. As cultural content, however, its value depends on the experience of the contents of the cultures. If this were not the case, the anthropologist could in principle be replaced by a robot.
- 16a. Results of scientific research constantly change our world picture. What does a total system do? It changes the totality. It changes everything. Scientific research changes something, but only within a philosophical framework. Intimate familiarization with a system involves incorporating a total view in which the results of research are interpreted and reflected in society. Thereby research and its results also change.
- 16b. Insofar as the results of research are intercultural, they provide guidelines for verbal and nonverbal behavior, but they do not deter-

SOME CONCLUSIONS

mine behavior and they do not delimit the individual contents of experience. Hence, as part of deeply different cultures, “the same” physics will differ in regard to content.

Over time, a cultural change has an effect on everything, including science.

- 17a. How can it be correct, strictly speaking, to say something about systems in general? It cannot be strictly correct. Language, however, may be used to suggest and guide the attention without leading it to any definite object. The statements of the general doctrine of systems, if one could give some hints about systems with such a pretentious title, cannot be precized beyond certain limits.
- 17b. The same applies with greater clarity to statements about cultures in general.
- 18a. From the idea that “much might have been different,” Leibniz and other thinkers have introduced concepts of ‘possible’ and ‘imagined’ worlds in contrast to the actual one. Does scientific research or philosophy have the means to designate some specific world as the *actual* one? No. Factuality has criteria that vary according to the standpoints adopted in ontology, epistemology, methodology, and other fields. This does not reduce the usefulness of the distinction between possibility and actuality as long as a specific frame of reference is presupposed and not taken as absolute.
- 18b. These points of view apply to cultures as well.
- 19a. Does scientific research or philosophy have the means to single out some particular world as the *real* one? No. No indicated fact can be a common point of departure for all philosophies. Furthermore, the criteria of reality contain evaluations or norms of a more profound kind than merely instrumental ones. Even if all philosophies sought to accept the same norms as points of departure—for example, the same rules of inference—this would not imply that other rules must be excluded.
- 19b. In the case of cultures, it is even clearer than with philosophies that we cannot point out one culture whose norms and world description depict reality itself.
- 20. Does this mean that human knowledge has specific limits? No. Our vague negative conclusions cannot be strongly precized without ei-

Some Conclusions

ther losing universality or becoming meaningless or inconsistent. Hence, they cannot be said to draw any definite borderline for the limits of human knowledge. We have no objective grounds for clearly delineating what the borderline should border on, and the very distinction between “real” and “possible,” as used in the preceding, is itself problematic.

Series Editor's Introduction

Arne Naess — A Wandering Wonderer: Bringing the Search for Wisdom Back to Life

{The pre-Socratics'} attitude, in the main, was genuinely scientific whenever it did not merely embody the prejudices of their age. But it was not *only* scientific; it was imaginative and vigorous and filled with the delight of adventure. They were interested in everything—meteors and eclipses, fishes and whirlwinds, religion and morality; with a penetrating intellect they combined the zest of children.

From this point onwards, there are first certain seeds of decay, in spite of previously unmatched achievement, and then a gradual decadence. What is amiss, even in the best philosophy after Democritus, is an undue emphasis on man as compared with the universe.

Bertrand Russell, *History of Western Philosophy*

When the full scope of Arne Naess's philosophical contribution is examined carefully and placed in context, it will very likely be viewed as one of the twentieth century's most significant and enduring.¹ Naess has made bold and innovative contributions to conventional academic philosophy and social research, particularly in the areas of behaviorist epistemology, empirical semantics and communication theory, scepticism, scientific and cultural pluralism, Gandhi and Spinoza scholarship, normative systems theory (as a general approach for exploring premise-conclusion relations), and the very idea and relevance of total systems (total views in Naess's *lingua*). Perhaps even more significant—although one should not view it as distinct or decoupled—has been his commitment to reconnect philosophy to life experience. This effort is similar to Bertrand Russell's in that it has been particularly pronounced in later life. Naess, however, carries this commitment to expand philosophy's sphere of concern to life in general

SERIES EDITOR'S INTRODUCTION

and the Earth. Essential to this endeavor, is the mature Naess's radical initiative to reconceptualize reason expansively, to integrate reason with emotions and feelings *in practice*. In some cases this includes using mythopoetics to make a case or communicate a point.² What makes Naess so special is that even while paddling against the current, he exhibits tremendous optimism and openness, joy, and a disarming, infectious playfulness.

Naess strives to *live his philosophy*. For more than thirty years, he has sought to reshape the philosophical debate by drawing from and building on his previous work to outline a nondualistic, nonanthropocentric philosophy of life that affirms the ultimate unity and interdependence of all living beings, while maintaining their individuality. His philosophy celebrates the Earth's richness and diversity—both cultural and biological. That said, one of the main purposes of the *Selected Works of Arne Naess* (SWAN), however, is to provide you, the reader, with the resources to make your own informed judgment regarding the significance of Naess's philosophical legacy.

At age ninety-two, Arne Naess has lived a long life filled with wonder. In his words, he has “seen life”—traveling the world, spending significant periods of time on every continent. He has experienced the world somatically and intellectually in concert as one mind-body—as a being—and seen more than most of us can imagine.

When Naess was born, Archduke Francis Ferdinand was alive, automobiles were in their infancy, and most homes did not have running water. Home refrigerators had just begun to be produced. Television and computers were only imagined. Only a few years before, after being contemplated for millennia, the first controlled and sustained powered flight took place, ushering in a period of ever-accelerating transfer of materials and information, but not necessarily a commensurate increase in knowledge or wisdom.

Consider that Naess has lived through two world wars (and too many “limited” conflicts to count), the rise and fall of the Soviet Union and East Germany, the “liberation” of India and Pakistan, the onset of climate change, and the hastening of “global terrorism.” He has been the beneficiary of tremendous medical advances and unprecedented economic growth, and he has seen the ravages caused by escalating consumption, globalization, and disparities in both income distribution and access to resources. He is part and product of humanity's largest growth spurt. And he has witnessed the most significant loss of cultural diversity and the onset of what

SERIES EDITOR'S INTRODUCTION

may become the planet's greatest extinction crisis—but is surely the greatest extinction crisis ever caused by one of Earth's own species. Naess has also seen and, at times, participated in the many hopeful responses to these ills—the peace, social justice, and ecology movements; nonviolent actions to support antiglobalization efforts and protest dam building; voluntary simplicity; conservation biology; wildlands philanthropy; bioregionalism; green business and architecture; ecological design, economics, engineering, and restoration; and sustainable agriculture, forestry, and fisheries management.

Everyone is influenced by the times and events of his or her day. The “prejudices of our age” filter into our lives and work more or less consciously and actively, but at a minimum they enter passively. What is the mature Naess's approach to philosophy, how is it a uniquely self-aware and responsive product of his day, and why should it be seen as monumental?

Naess likes to see himself as a “philosopher of life.” The thought of simply being an academic philosopher—living a life of the mind—makes him restless and uneasy. For Naess, “wonder” is both the point of departure for philosophy and the focus of the enterprise. He is the philosophical equivalent of a hunter-gatherer using his wits and intuition to seek out food (for thought) in a fecund landscape. As they were for the ancient Greeks, science and philosophy are inextricably intertwined for Naess. Science, as the application of reason through empirical investigation, cannot be separated from rational reflection on the nature of reason, and vice versa. For the mature Naess, though, philosophy and science are also distinct. Philosophy is the unique realm in which we take up the deepest, most profound, and most fundamental problems. From Naess's vantage, which defines philosophy openly and discursively, the questions that have fascinated and plagued people for millennia have not changed much and they are not likely to change significantly in the future.

Naess's view of philosophy includes the traditional epistemological question “What can we know?” and the ontological question “What main kinds of things are there?” But it also includes “How do we measure?” and “How do we know?” as well as “What is the relationship between the knower and the known?”³ These are questions that are likely to vary with cultural and social circumstances, but this does not, for Naess, imply cultural relativism. By its nature, this view of philosophy runs counter to the dream of the logical empiricists; it cannot be restricted to investigations of

SERIES EDITOR'S INTRODUCTION

“fact” or “logic.” It is imbued with fundamental valuations. Being a philosopher, for Naess, is thus a deeply personal and intimate matter that requires us to engage all of our powers and experience. It should also include questions such as “What are your aims in life?” and “What’s driving you?” as well as encourage a practice of deep and open argumentation by asking repeatedly, “Why do you hold that *p*?” in order to unearth underlying premises and hypotheses. For Naess, all these questions have an empirical component. He sees it as a duty for a philosopher to extend research into the creation and use of empirical methods to address these aspects, unless these questions can be adequately addressed by an existing empirical science, in which case it is fine for a philosopher to perform research here, but it no longer constitutes a *duty*.

In Naess’s view, philosophy is ultimately concerned with how *we*, through our experiences, perceive the world, the world’s relation to ourselves, and the basic features of the condition of people. It is the realm in which we pose sophisticated questions to address perennial problems, probe them from different angles (in Naess’s case, from as many angles as possible), and test and apply the insights to real life—to what we do and decide every day. Its purpose is not to arrive at definitive answers. The purpose of philosophy, rather, is to help us understand what *we* believe in from our innermost perspective, expand this perspective continually, and facilitate communication—so that we might contribute toward improving the state of affairs of the world.

While initially attracted to Bergson’s *les données immédiates de la conscience* (the immediate data of consciousness), Naess grew disenchanted when he recognized that one becomes lodged in an endless circular loop and never exits consciousness. Naess clearly believes that the unexamined life is not worth living (his life is a testament to Socrates’ edict), but he appreciates that disembodied, introspective examination comes at great peril. A mind-centered focus on “examination”—where subjects exist separately from objects, theory is isolated from praxis, and knowledge is decoupled from wisdom—very quickly degenerates into meaninglessness. Worse yet, separating people from and raising people above nature and the coevolutionary process that created us—and provides for our sustenance—can be inimical to life and the evolutionary process.

Nature, that which is, the reality of the pre-Socratics, is Naess’s philosophical palette, not the “world” of his own consciousness as has become

the norm with so many contemporary philosophers since Descartes. Popper and others posit the existence of three worlds that correspond to the development of our commonsense view of reality. World I is the physical world, the "external world," the world of our sensory impressions. World II is the world of all conscious experience, the psychological world of the "immediately given," which incorporates our feelings and intentions. World III emphasizes the logical content of reality. Naess finds these multiple views of reality unconvincing and potentially dangerous. With a world-view inspired by Spinoza's *Ethics*, he is fundamentally opposed to the notion of multiple worlds.

Naess's mature philosophical approach and contributions are shaped by full engagement with a relational reality, in which no firm subject/object, substance/property, universal/particular, fact/value dualities exist. John Muir's famous, deceptively simple aphorism sets the stage: "When we try to pick out anything by itself, we find it hitched to everything else in the universe." Reality as we experience it, according to Naess, is a dynamic, multilayered manifold of hierarchically related gestalts—of which we are always a part. It is the opposite of atomism. Contrary to the dominant, Western way of viewing reality, there are no extrinsically connected discrete objects or "things in themselves" in the sense of Kant's *Ding an sich*. With Naess's "gestalt ontology," there is no dualistic "I" standing outside of reality looking in. Living beings, individuals in the sense of Spinoza's modes, are spatiotemporal manifestations of "one substance," nature or reality. As Naess points out in *Freedom, Emotion, and Self-Subsistence* (SWAN VI), Spinoza's medieval terminology of substance, mode, attribute, God, and Nature is dispensable. In addition, Naess goes on to characterize "living beings" broadly to include individual organisms as well as ecosystems, rivers, mountains, and possibly Earth (Gaia).

Naess's view of reality calls for a gestalt shift. His gestalt ontology does not stop with gestalt psychology's simple notion of holism, where the whole is more than the sum of the parts. It goes on to add that the internally related subordinate gestalts are themselves more than mere parts. There are no parts as parts or wholes as wholes; higher-order wholes are not reducible to lower-order wholes. The concrete contents of reality have gestalt character. For Naess, we experience reality spontaneously and our experience of the world is made up of gestalts. "[This] is the world we experience. Nothing is more real."⁴ People create abstract structures to re-

SERIES EDITOR'S INTRODUCTION

flect on or analyze spontaneous experiences and their structure; they are the interrelations between spontaneous experiences. Mind and body are mental contrivances and conveniences—abstract structures in Naess's parlance—for helping us to describe, model, or understand certain states of affairs. They are not the contents of reality. Only individual occurrences of spontaneous experience make up the concrete contents of reality.

What are the consequences of Naess's "ontological realism" as expressed in the form of gestalt ontology? First, living organisms have different levels of access to reality, based on their capacities, experiences, and backgrounds. This implication of "reality is one" plays a central role in the mature Naess's approach to philosophy of science. One of his main thrusts is to undermine the claim that the exact physical sciences show all that is, that they have a privileged view of reality. In his view, science creates extremely abstract structures of what is real, but those structures do not actually *describe* any of reality's concrete contents (descriptions are themselves normative). Jakob von Uexküll, the famous ethologist of the early twentieth century, whom Naess read closely in his youth, helps clarify this notion. "As the spider spins its threads, every subject spins his relations to certain characteristics of the things around him, and weaves them into a firm web which carries his existence."⁵

Different people experience reality differently, yet we often, incorrectly, speak of *different realities* as if they existed. By the same token, identical accounts of reality in no way imply verification of that view by correspondence; from Naess's perspective, such accounts by themselves are merely a sign of cultural poverty. "God" could have created the Earth and life 6,000 years ago, but the evidence to support this case is thin and the evidence to support evolution is stronger, in part because biological science and paleontology generally employ a greater level of depth of intention and thus aspire to maintain higher standards for the evaluation of evidence. Radical pluralism and scientific possibilism do not imply scientific or ethical relativism.

There are at least four other key implications of Naess's gestalt ontology. First, the existence of one, interdependent reality tends to curb solipsism. Second, the world we live in spontaneously can no longer be characterized as merely subjective. Expressions such as "the social construction of nature" become oxymoronic. Third, individual organisms exist as knots in a biospherical web or net. Reality is not anthropocentric; it is not particu-

lar to humans. Fourth, humanity can no longer justifiably be seen in opposition to a separate object—nature. This insight tends to temper any “natural” tendencies toward anthropocentrism. As with Leopold’s Land Ethic, people become plain members and citizens of the biotic community, albeit ones with unique powers and proclivities and thus special responsibilities. We are all individual beings, yet we vary in the extent to which we are integrated into the whole.

Humans are massively altering the gestalt character of reality, diminishing it, making it less complex. We do this, Naess argues, without necessarily recognizing we are doing it or the extent to which we are doing it. Thus, we are unable to evaluate the tradeoffs of making such decisions. Naess argues that we generally act simply according to how we “see” reality, but there are aspects of reality that may not be available to us. These aspects are no less there because they are currently unavailable to us, yet they can be destroyed very easily. Sometimes we also confuse our abstract structures of reality (models, data, concepts, etc.) with the contents of reality and vastly underestimate the complexity of internal relations between gestalts, leading ourselves to believe, incorrectly, that higher-order wholes can be reduced to lower-order wholes. It is Naess’s hope that by embracing gestalt ontology, we are encouraged to cultivate our opportunities and faculties for experiencing reality more fully—for experiencing more complex, higher-order gestalts. It is also his hope that we will openly and more carefully consider, in advance, how a proposed research program, action, or decision might affect other peoples’ (or other life-forms’) opportunities for rich spontaneous experiences (consider, for example, the possible impacts of ostensibly beneficial research on nuclear fission or molecular biology). In the end, however, we should remember Naess’s own caution—his description of gestalt ontology is itself an abstract structure. As Naess says, “For me reality has always been something slippery to handle. I seem to grasp it firmly, but like an eel, or even a small lively trout in shallow water, firmness of grasp does not guarantee against escape.”⁶ But does reality really have gestalt character?

Truth—as in *the* truth—is not a defensible notion for Naess. For too many academic philosophers, wonder has been extinguished and replaced by a belief that definitive answers have been found, that the original, initially vexing questions can be laid to rest. Naess is under no such illusion. He views humans as essentially fallible and he sees this domain of fallibil-

SERIES EDITOR'S INTRODUCTION

ity as extending to mathematics and formal logic. This may be why he so freely returns to previously explored material (sometimes just after writing it) and looks at it afresh, with new and frequently competing and even conflicting insights. For Naess, truth is something we seek continually without expecting or believing that it can be found. He seeks peace of mind (*ataraxia*) by suspending judgment (*epoché*). While necessity requires him to take firm positions in life, he often resists taking such positions in his written philosophy. Having reached a general state of mental suspense (*isothenia*), he prefers, as a mature sceptic, anticipating his own tendency to come up with counterarguments and counter-counterarguments, to suggest alternative paths, inspire new ways of looking at things, and foster informed, open-minded debate. This *zetetic* inclination, although nascent in many of his earlier works, was made explicit and became a central theme in his philosophical writings in the 1960s.

For Naess, passivity has no place in philosophy or life. In his famous debate with Sir Alfred Ayer, Naess defines Spinoza's *amor intellectualis* as a "kind of loving attitude towards what you have insight into, while considering it in an extremely wide perspective."⁷ For the mature Naess, *amor intellectualis* involves using his technical and intellectual training to articulate, in direct and forceful ways, his attitudes and evaluations on matters of practical consequence. Like Spinoza and Gandhi, Naess is concerned with human salvation in this world, but Naess, with his concept of "wide-identification," expands this concern to both humankind's relationship to life in general and the self-realization of all life-forms for their own sake. Whether it be understanding how lay people conceptualize truth or experts characterize democracy; considering how our approach to science not only shapes how we do science, but the nature of scientific outcomes too; using philosophy to improve practical communication; facilitating thoughtful debate on the potential dangers of Norway joining the European Union; or discussing the ethics of climbing, the meanings of sustainable development, or distinctions between different approaches for addressing the ecological crisis, Naess seamlessly connects philosophical questioning to activeness in relation to the questions.

Naess's philosophical career can be seen, in one sense, as an attempt to bridge C. P. Snow's two cultures. Believing that the central questions of philosophy are here to stay, he has developed his philosophy over seventy years in part through his effort to relate these questions to the issues of his

rapidly changing, trying, and tumultuous era. Naess's lifelong commitment to integrate interests in nature, science, and logic is evidenced by the mature Naess's championing of philosophical approaches in which both metaphysics and science contribute to all-embracing systems of thought. This approach is particularly prominent in Naess's development of normative systems theory, a strategy for promoting systematic reflection on premises and conclusions. Recognizing that all philosophical questioning must stop somewhere, Naess calls the essential intuitions that serve as bedrock assumptions for our total views, ultimate norms or ultimate premises. Further, recognizing that our philosophical conclusions as well as our lifestyles and everyday actions often appear inconsistent with these ultimate premises, Naess has developed a strategy for using premise-conclusion strings to help identify potential norm conflicts as well as to help assess whether potential agreements and disagreements are real or pseudo. Use of this technique figures prominently in Naess's approach for improving communication, in his approach for exploring both the philosophical basis for Gandhi's *satyāgraha* (active nonviolent resistance) and the Gandhian premise "Any human conflict can be justifiably resolved through nonviolence," as well as in his own Ecosophy T.⁸

With regard to total views—broad philosophical systems like Spinoza's, which attempt to communicate our deepest insights and communicate views of life—Naess argues that although the existence of complete, explicit total views is absurd, it is equally absurd to presume to criticize a total view without adopting one (at least implicitly). After relinquishing the possibility of creating a consistent empirical theory of knowledge, Naess came to believe that any theory of knowledge presupposes all major philosophical disciplines, at least on the metalevel. One cannot have a theory of knowledge without presuming a particular reality, at least implicitly, and this necessitates having an ontology, metaphysics, ethics, and so on. This has practical consequences too. We never simply act solely as a philosophy professor who specializes in logic or ethics; we are always, at least partly, mother, daughter, lover, scientist, . . . , and philosopher. If we accept the premise "For every decision we, explicitly or implicitly, take all things into consideration," then the notion of total views or total normative systems can be seen as very "useful fictions," which, if articulated, might help us to improve decision making.

Naess is careful to point out that he sees his own total view and others

SERIES EDITOR'S INTRODUCTION

as fragmentary and constantly evolving—ever “on the way.” Moreover, even if we could have a completely formed and integrated total view, we could not count on being able to articulate it. There will always be a tension between the Spinozistic goal of clarity and the pragmatic reality that in this world we can never wait until all the facts are in. None of these issues, however, justifies abdicating our responsibility to try to articulate our own total views. The mature Naess is a radical pluralist. He believes in defending coherent systems, without claiming that their relation to reality is definitive. While he is committed to the importance of models and systems, he is opposed to the idea that there could or should be a definite worldview. Naess’s hope is that there will be no definite scientific worldview in the future.

No Western philosopher since Descartes—except perhaps Spinoza, who has also been a primary inspiration for Naess—has had the potential to help us drastically reshape our relationship to each other and life in general: not by spelling out *a* clear and coherent total system—to be taken as *the* truth—but by challenging us to articulate our fragmentary total views and connect the abstract problems of philosophy to issues of contemporary social and political conflict. In Naess’s view, “[t]he full meaning of a theory can only reveal itself in practice, and practice is blind without theory.”⁹ To be a philosopher of life, one must embrace both theory and practice and engage them in dance.

In Norway, Arne Naess is regarded as a national treasure, a seeker and a seer, a “minor prophet,” in his own words. His radical pluralism and endorsement of diversity are demonstrated by his complex character. He has a proclivity for being aloof and charming, somber and joyful, accountable and carefree, arrogant and modest, slippery and precise. In a world of contradictions—breathtaking beauty *and* ineffable squalor and suffering—Naess is no exception. He is an antiguru guru. He strives for high levels of consistency and integration in his philosophy but accepts that in his personal life he cannot live up to his philosophical systems’ requirements. He strives for definiteness of intention, yet he appreciates vagueness and eschews dogma, refusing to be pinned down to a particular viewpoint or placed in a particular philosophical camp. This stance is further supported by his sometimes maddening tendency to revise, revise, and re-revise. As a consequence, one cannot go to any of his books

or articles and find the “definitive” Arne Naess. He is a troublemaker too, but the kind of troublemaker people want to have around because he challenges orthodoxies with an elfin irreverence. Naess stands out because his frequently outlandish and controversial views are felt deeply, reasoned carefully, and conveyed playfully.

Naess has had a profound influence on Norwegian academic life and the society as a whole. From 1939 to 1954 he was Norway's only professor of philosophy. He was chiefly responsible for organizing courses for the *examen philosophicum*, introductory examinations in logic, methodology, and history of philosophy that an entire generation of undergraduates (roughly 100,000 people) were required to take, regardless of their disciplinary focus. His unique paradigm of inquiry—emphasizing open-mindedness, empirical analysis, pluralism, a thorough grounding in philosophy and the history of ideas, and a vital concern for contemporary problems—is credited with shaping the intellectual fabric of postwar Norway. At a press conference for Naess's eightieth birthday, the Norwegian Minister of Education testified to the significance of the Norwegian version of Naess's *Communication and Argument*, one of the primary texts for the *examen philosophicum*. “We have all read it. We *still* cheat in argumentation, but now with feelings of guilt.”¹⁰

Naess is also credited with rekindling the study of philosophy in Norway and with forming the Oslo school of philosophy. The section on Scandinavian philosophy in *The Encyclopedia of Philosophy* elaborates:¹¹

The philosophical milieu in Norway today [circa 1967] is determined by an internationally known and original philosopher. . . . Arne Naess . . . is the originator of a radical type of empirical semantics and the leader of the so-called Oslo group. . . . The empirical methods applied by the Oslo group employ carefully worked-out questionnaires. By the help of such questionnaires and by teamwork, philosophers of the Oslo group have carried out investigations of such expressions as “truth,” “democracy,” and “private enterprise.” . . . If it is correct that Norwegian philosophy has had a dead period,¹² it is equally correct to assert that, primarily because of Arne Naess, Norwegian philosophy is now in the middle of a period of life and growth.

When asked to comment on this passage, Naess was emphatic about inserting an addendum to the last sentence.¹³ He was proud to convey that contemporary Norwegian philosophers pursue a wide variety of directions and employ a diversity of approaches, many independent of Naess's own

SERIES EDITOR'S INTRODUCTION

line. This point is borne out by the more than forty-four permanent teaching positions currently at the University of Oslo's Institute of Philosophy and the broad spectrum of approaches these philosophers pursue, from the analytic tradition to phenomenology and from existentialism to hermeneutics. As one of Naess's successors, Alastair Hannay, in his section on Norwegian philosophy in the *Oxford Companion to Philosophy*, has commented, "Norway enjoys a varied and vigorous philosophical life. . . . Philosophy's place in Norwegian academic life, as in the society at large, is due in large measure to Naess."¹⁴

The reach of Naess's contributions to philosophy and social research extends well beyond Norway. Significant international recognition has also come his way for these contributions. He has received the Peer Gynt Prize awarded by the Norwegian Parliament (2004), the Nature and Environment Prize from the Nordic Council (2002), the Nordic Prize from the Swedish Academy (1996), the Mahatma Gandhi Prize for Non-violent Peace (1994), and the Sonning Prize for contributions to European culture—Denmark's version of the Nobel Prize (1977). He has even been honored by five festschrifts, one each for the occasions of his seventieth, eightieth, and eighty-second birthdays and two for his eighty-fifth birthday.¹⁵ He is the founding editor of the influential journal, *Inquiry*, created to promote collaboration between philosophers and social scientists. He is also a renowned mountaineer and climber, an occasional nonviolent political activist, and father of the deep ecology movement. His social concern, sense of wonder, and trickster nature have all contributed to his success at numerous academic posts around the world—preferably near mountains or deserts—from Berkeley to Jerusalem and Helsinki to Hangzhou. He is, to this day, still a frequent international speaker.

Even with this high level of accomplishment, the significance of his work as a whole—as a gestalt—has yet to receive broad-scale appreciation outside of Scandinavia. There are many explanations for this situation.

The overarching reason has likely been the general inaccessibility of his oeuvre. This inaccessibility has many facets. Naess has been incredibly prolific, producing over four hundred publications, more than thirty of which are books. These publications span topics from argumentation theory to zeteticism, with adventures along the way at such seemingly incongruous destinations as climbing ethics, cultural anthropology, and deep ecology. His range of topics—in abundance, breadth, and depth—is try-

ing, at best, for our increasingly compartmentalized and specialized academic communities.

In addition, the bulk of his most significant works have been out of print for quite some time. Many of the earlier editions of the books were edited poorly and documented sparsely. A significant portion of his important articles and book chapters appears in obscure or difficult-to-find books and journals, and much of his work has remained unpublished (at least two hundred papers and several book-length manuscripts). Naess's main works appear in three primary languages, German, Norwegian, and English, although he has also written in Danish, Swedish, and French. Finally, Naess's prose can be dense and opaque, if not downright confusing. Although this trait is by no means unusual for a philosopher, when blended with Naess's appreciation for vagueness and ambiguity, his aversion to authoritative stances, and his tendency to revisit topics by reconsidering earlier viewpoints, the already high entrance fee can become prohibitive.

The boundless range of Naess's interests and the general inaccessibility of his entire oeuvre have led some scholars to view him rather pejoratively as a dilettante. Some of these critics view him as flitting from one area of interest to another, not mining any to its logical conclusion; some see him as throwing away a great talent in logic; some view his social research, especially his work with questionnaires on lay people's and experts' perceptions of philosophical concepts and his use of statistics, as outside the realm of serious, professional philosophy; and still others see him as inappropriately conjoining his philosophy with activism. His breadth has even led a few of the more extreme critics to dismiss his work out of hand. Although some of the criticisms detailed above do have merit, in my view Naess gives the dilettante a good name.

To address this range of concerns, the *Selected Works* project was conceived. The project was the brainchild of Douglas Tompkins. "Miracle Doug," as Arne refers to him, is the founder of the Foundation for Deep Ecology and is himself a renowned climber and kayaker in addition to being a wildlands philanthropist who has helped protect immense tracts of land in Chile and Argentina, some as large as Yosemite. The *Selected Works* would have simply remained a "great idea" without Doug's generosity and support. The project was initiated in 1994 and commenced editorial work in 1996 under my direction.

In the introduction to his *Four Modern Philosophers: Carnap, Wittgen-*

stein, Heidegger, and Sartre (1968), Naess decries the condition whereby the philosophical life of an individual is set by the local philosophical scene, by provincial biases, or by what is easily accessible.¹⁶ Such accidents of environment should not, in Naess's view, play a pivotal role in shaping a budding philosopher's development. I see the *Selected Works*, at least in part, as a response to this predicament.

The purpose of the *Selected Works* is to bring—for the first time—the full scope of Naess's philosophical contributions to the English-language audience in one collection of highly readable and meticulously edited volumes that adhere to the highest standards of contemporary academic philosophical publishing. The *Selected Works* is, however, by no means exhaustive; it is not a collected works.¹⁷ We have simply aspired through careful selection to offer a representative and relatively expansive collection of Naess's principal writings. As such, the *Selected Works* is the definitive repository of Naess's oeuvre, chronicling the development and progression of his thinking for scholars, students, and critics alike.

In the remainder of this essay, I attempt to sketch briefly one possible version of an intellectual biography for Arne Naess. I endeavor to trace some key influences on Naess's philosophical development, discuss the evolution of his philosophical outlook, and touch on the relevance and significance of each volume in the *Selected Works*. I close with a short note on our editorial approach.

From Scientism to Wisdom: Toward a Philosophy of Life

The philosophic researcher should be task-minded, not discipline-minded, and should follow his questions wherever they lead.

Arne Naess, "Norway"

Arne Dekke Eide Naess was born in 1912 in the dining room of a large house with a wild, expansive garden. The house was on the outskirts of Oslo in Slemndal, a short walk from where Naess lives today. Arne was the unplanned fourth child of a wealthy family from Bergen. Before he was a year old, his father, who was ill with cancer, had died. Overwhelmed, his mother, Christine, entrusted little Arne to the family's governess. This is where his first memories begin.

Arne speaks of Mina, his governess, endearingly. She is described as satisfying little Arne's every wish, be it procuring live flies for his bath or

bringing a trunk filled with bottles on a family trip so that he could continue his water-play experiments. Sometime before Arne was four, Christine dismissed Mina, ostensibly for spoiling Arne too much. This initiated a deep rift between Arne and his mother, which was never to be mended. It also set in place a sense of loss, alienation, and resistance to emotion that profoundly influenced Naess's early personal and philosophical development.

Significantly later, after an intensive six-day-a-week, fourteen-month psychoanalysis with Freud's noted collaborator Dr. Edvard Hitschmann, Naess came to understand his impenetrable shell that keeps others at arm's length (*Panzercharakter*, in Freudian terms) as resulting from a reaction to his mother's unreliability and emotional hysteria. His effort to keep his mother at a distance morphed into a general aloofness and distancing. The adolescent Arne began to favor an "objective," bureaucratic approach to language. He saw art, music, and poetry as being seduced by emotion, by beauty and form, but viewed science and philosophy as realms from which such emotions should be banished. This prejudice would take decades to overthrow. At this time he also developed a single-mindedness and resistance to inconvenience and pain that to this day make it easier for him to concentrate and focus. As Hitschmann pointed out, however, this inward turn has a flip side, a certain self-destructive or masochistic bent that was later to plague him, particularly in his relationships with women and his children.

Much of Arne's early childhood was spent at the seashore, and this is the period in which his interest in nature and experimentation began to flourish. Feeling somewhat distanced in his relations with people, he identified with nature, especially little sea creatures. He waded in shallow water for hours, inventing experiments to test nascent hypotheses about the behavior of small sole, tiny translucent shrimp, and crabs. He describes these experiments as engendering an early enthusiasm for diversity and a tendency to suspend judgment on the nobility or status of different beings. He loved these creatures for their unique qualities and their amusing adaptations and limitations. They inspired a certain egalitarianism, which took hold and later influenced his philosophical approach in profound ways.

Young Arne was restless. He had an early penchant for "collecting" and organizing large groups of numbers, stones, and stamps. He started climbing trees in the family's little "wilderness" before he was five and

SERIES EDITOR'S INTRODUCTION

soon progressed to big firs and spruces. He found that he enjoyed being able to watch people from above. Arne outgrew trees fast. His desire for perspective and the opportunity to survey broad areas was rapidly transferred to mountains. At the age of five, he began going to his mother's small mountain cottage in the town of Ustaoset, high in the Hardangervidda between Oslo and Bergen. By the age of eight, he had adopted Hallingskarvet, a bread-loaf-shaped mountain about three and a half hours' walk from Ustaoset, as his surrogate father. In his teenage years, this obsession for expansive perspectives translated into a lifelong passion for mountaineering. When Naess was sixteen or seventeen he climbed the 106 tallest mountains in Norway. It was around this time that he was first introduced to Spinoza's *Ethics* by a Norwegian Supreme Court justice that he met in the mountains. Naess's desire for a broad and open perspective, for seeing things in totalities (god's-eye view), translated to his studies. Young Naess read widely in economics (especially value theory), science, philosophy, history of philosophy, and the Earth's biological history.¹⁸ This commitment to cultivate an ever-expanding perspective would later potentially influence his approach to philosophy.

Arne's youth was spent captivated by piano, study, and mountains. His decade-older brothers took it upon themselves to toughen up their timid younger brother, as well as introduce him to the ways of the world and scholarship. When Arne was only eight, his eldest brother, Ragnar, left for America to study for a Ph.D. in chemistry at MIT. Ragnar later went on to receive one of the Harvard Business School's first degrees and became a successful stockbroker in the United States. Erling studied economics and went on to create an international shipping empire; he became famous for his assistance to the Norwegian government-in-exile during the Nazi occupation. His sister, Kiki, married a German doctor and after the Second World War returned to Norway to become a physical therapist. From Kiki he learned the power and significance of offering encouragement to others. During his early years and well into adulthood, Arne's tight-knit relationship with his siblings provided security and support for him to "find his own way" — *sva mārga*, to use one of his favorite Sanskrit terms. Although he tended not to seek their financial assistance, his wealthy and generous brothers offered a sense of comfort, safety, and the occasional extravagance, which in later life made it easier for him to live his bon mot, "simple means, rich ends."

SERIES EDITOR'S INTRODUCTION

Naess studied philosophy, mathematics, and astronomy at the University of Oslo. At nineteen, after completing the equivalent of an undergraduate degree, he left Oslo to continue his studies in Paris. Naess was put off by the adoration Bergson received in Paris, but ultimately left to seek broader vantage points, cheaper living, and better climbing opportunities. After completing two master's theses at twenty-one, one exploring discussion about the concept of truth and the other exploring the use of behavioral psychological principles to judge truth validity, Naess left Oslo again, this time for Vienna. In Vienna he took master classes in piano, where, following his trickster nature and as a response to the strict taskmaster Fuchs, he "learned" new material. When he ran out of pieces he had long since mastered, he quit. Thinking that it was necessary for philosophers to have high levels of self-knowledge, he underwent intensive psychoanalysis with Dr. Edvard Hitschmann. As a part of that process he assisted with the treatment of patients in a psychiatric hospital and developed tremendous empathy for the suffering of humankind. While in Vienna, he was also warmly welcomed at the famous Schlick seminar.

The logical empiricists' friendly, equiminded approach to discussion made a great impression on Naess, but he was not equally affected by their ideas.¹⁹ The young Arne was impressed by the preciseness, empirical nature, and lack of emotion in science—he wanted to practice philosophy with a scientific bent and he wanted to test philosophical hypotheses with experiments. He was already interested in perennial philosophical problems and did not believe that most of them were ultimately pseudoproblems that could be solved by investigating inconsistencies in language. His most significant philosophical issue with the logical empiricists was not that they were empirical, although he believed they were misguided in thinking that any philosophical problem could be wholly empirical, but that they were ultimately antiempirical in their belief that a logical grammar of language was more suitable for investigating the use of terms than statistical analysis of their actual use. Naess's detailed critique of the logical empiricists' position and reflections on his personal experiences attending the Schlick seminar appear in volume VIII. In this critique, Naess expresses a concern that in their interpretation of terms, many philosophers (not just the logical empiricists) were artificially constricting the range of possible interpretations and thus unintentionally reducing potential insights regarding the diversity of tenable positions on problems of vital

SERIES EDITOR'S INTRODUCTION

concern. This perspective presaged his later views, particularly those expressed in *Interpretation and Preciseness* (SWAN I), and his later approach to cultural anthropology and philosophy of science. Naess sums up his general perspective on the state of philosophy at the time with the following remark: "The turn of (Western) philosophy in [the twentieth century] towards language rather than cosmos, towards logic rather than experience in the broadest sense (like that of William James), is a turn into a vast blind-alley."²⁰

While in Vienna for fourteen months in 1934 and 1935, Naess made final revisions to his doctoral thesis, *Erkenntnis und Wissenschaftliches Verhalten* (Knowledge and scientific behavior).²¹ Although Naess drew inspiration early on from Russell and Whitehead, his doctoral thesis can be seen, in part, as support of the American Pragmatists (James and Dewey) in opposition to Russell and early Wittgenstein. According to Dewey, the main purpose of his philosophical writings was "to reintegrate human knowledge and activity in the general framework of reality and natural processes."²² Naess did just this by creating a radical and unique approach for exploring how high science is performed, a sort of science of science. At this point, Naess believed it was possible to use such an approach to obtain a complete account of all science within one system. Inspired by the ethologist Uexküll's "special biology" (*Umweltforschung*), Tolman's "objective" behavioral psychology ("molar" behaviorism), and the cultural anthropologist Malinowski's work on speech and nonverbal behavior, Naess took on the standpoint of a neutral, nonparticipant spectator and outlined a program for an empirical metascience of science, an ethological approach to epistemology of science.

Naess used the idea of a dispassionate visitor from another solar system coming to study Earth-based scientists to demonstrate the possibility of completely describing both the activity of researchers and the contents of knowledge without drawing on the subjective models that governed traditional epistemology and presupposed knowing subjects or minds. The idea was to study or rather "witness" science similar to the way experimental psychologists study rats, but without falling into the trap of imposing their own experience of reality and their preexisting conceptual models of reality ("maze epistemology"), or their scientific pretensions. In the view described in *Erkenntnis*, knowledge is cognition—it is an activity with intention—and this helps to dismantle the subjectivist dualism between the

content of knowledge and the activity of research. Naess's interest was in describing these patterns of research activity. He argued that the *terminology* associated with scientific activity—which is bound to the subjective-reality model—changes in leaps and bounds, not the *patterns of research activity*, which are in constant, but gradual, flux. With this argument that change in science happens gradually, by generalization and differentiation, Naess foreshadowed his response to Kuhn well before *The Structure of Scientific Revolutions* was published in 1962.

With *Erkenntnis*, Naess also anticipated ideas that later became prominent in linguistic philosophy, such as the importance of ordinary language over formal systems and the importance of using observation of contrasts and discriminations to build up understanding of systems. In the end, presaging his own radical pluralism to come, Naess seems to relax his early position on the importance and possibility of creating a metascience of science from the “far outside” and ultimately comes to view subjective and behavioral models as two different point-of-departure formulations in an indefinite plurality of equally valid approaches for a metascience of science. This refined perspective is taken up in Naess's 1965 article “Science as behavior” (in SWAN IX), which returns to the prospects and limitations of creating a behavioral metascience to study the scientific enterprise, but this time from the “near outside.”

At age twenty-four, after receiving his Ph.D. from the University of Oslo for his work on science as behavior, Naess returned to his interest in the problem of truth. A particular concern was the inadequacy of philosophers' intuitive methods for capturing how lay people conceived and used the term *true*. In 1937 and 1938 he developed and tested an empirical approach for using questionnaires and statistical analysis to investigate non-philosophers “commonsense” views on the notion of truth. He then related these notions to philosophers' theories of truth. Naess found an amazing diversity of views among the amateurs. He also found that their views, although typically devoid of philosophical pretensions, generally covered the views represented by professional philosophers. This work elicited substantial controversy, most of which came from philosophers who viewed it as undignified to use questionnaires and statistics to investigate one of the great problems of humanity. Naess's results were published as “*Truth as Conceived by Those Who Are Not Professional Philosophers*” (1938). A summary of this work is presented in Naess's “Common Sense and Truth” (in SWAN

VIII). Naess's continued application and refinement of these techniques would evolve into empirical semantics.

In 1937 Naess fortified his lifelong fascination with the arctic climate Hallingskarvet by building Tvergastein, his now-famous rustic and remote hut, at its base, a three-and-a-half-hour trek from the train station at Ustaoset. He outfitted the hut with Rube Goldberg oil lamps that also served as stoves for warming tea and with an eclectic library of teach-yourself language manuals, Sanskrit-English dictionaries, astronomical and wildlife field guides, novels by Dostoyevsky and Ibsen, letters of Spinoza, and a complete philosophy library. Following his passion for amateur science he also created "institutes" of petrology, chemistry, zoology, hydrology, and botany at Tvergastein. Naess has written the bulk of his work at Tvergastein and spent the equivalent of about twelve of his ninety-two years living there. The enormous open views at Tvergastein afforded Naess the distance and perspective he so craved while insulating him from philosophic fashion and dogma. Here he had the luxury, freedom, and good fortune to pursue his own interests free from the banalities and distractions of academic life. After completing what is now Tvergastein's main room, Naess went on to perform postdoctoral research at Berkeley (1938–39) with the pioneer of empirical psychology, E. C. Tolman. At Berkeley, he went from studying the behavior of rats faced with many possible alternatives to studying the behavior of the scientists studying the rats.

Naess returned to Oslo in 1939 to be appointed to the University of Oslo's Chair of Philosophy at the age of twenty-seven. On April 9, 1940, German forces invaded Norway; it would remain under Nazi rule for the next five years. This was a harrowing time for academics throughout Europe. Arne tried to maintain his unruffledness, pouring himself into research and curricular reform initiatives intended to widen and expand the perspective of university undergraduates. He tried to stay at Tvergastein often, and this afforded him some peace and solace in a world of great tension. Before long, however, even he was drawn into the resistance movement. In the fall of 1943 he played a central role in foiling a Nazi attempt to deport University of Oslo students to concentration camps for "re-education." The University was subsequently closed and Naess became even more committed to the resistance movement and his research. By this time he had developed great admiration for Gandhi's catalytic 1930 *satyāgraha* campaign, the march to Dandi in protest of the British salt tax.

Naess was greatly impressed with Gandhi's idea of trying to meet one's opponent in a manner that would calm passions and facilitate truthful communication. He thought such an approach could have had a significant effect on quenching the Nazi expansion, *if* the necessary infrastructure to support *satyāgraha* had been created in European countries. After the war, Naess used these insights in his efforts to bring together suspected torturers and the families of torture victims to gain a sense of closure on the fate of their loved ones—and to avoid having the “traitors” subjected to equally horrid persecution. In 1948 Naess was invited to be the scientific leader of a new UNESCO project created to explore ideological controversies between the East and the West. He was soon off to Paris again, this time to pursue his interest in using philosophy to address questions of social and political importance.

The Cold War was a tinderbox and two core ideological conflicts revolved around use of the terms *democracy* and *freedom*. Naess was asked to address both but countered that UNESCO's requirement that he deliver a report within one year made it essential for him to consider *democracy* first. His goals were to clarify what people mean when they use the term *democracy* and to understand the causes of ambiguity and confusion that result from its use. After an extensive literature review, which chronicled historical usage of the term, Naess and his assistant, Stein Rokkan, prepared a thirty-question survey that was distributed to almost 600 international experts in the fields of philosophy, law, history, political science, sociology, economics, communications, and logic. Naess used the roughly 100 replies to create an empirical study of “agreements” and “disagreements.” The study demonstrated *democracy*'s richness, diversity, and multiplicity of meanings and thus undermined its misuse in both the East and the West. This incited detractors from every ideology, who roundly criticized the resulting report, *Democracy in a World of Tensions*, which according to Naess “was promptly sold out and never reprinted by UNESCO due to the politically dangerous character of its items.”²³ Naess's “Analytical Survey of Agreements and Disagreements,” along with two other pieces on ideological convictions and rationality, appears in SWAN IX.

The UNESCO democracy study was the first and last international, large-scale application of Naess's empirical semantics approach. He was originally interested in doing another study on “cultural diversity,” but neither this nor the “freedom” study came to fruition. Naess learned—

SERIES EDITOR'S INTRODUCTION

much to his chagrin, and as his superiors had warned—that UNESCO was a place for writing reports; it was no place for conducting research. Naess's frustration with the UNESCO experience and his wanderlust for the perspective of mountains led him to daydream first, and then to "pursue non-essentials":²⁴

The arguments against abandoning the imaginary joys of the Himalayas for an actual expedition seemed strong to me, and so they still do. But in the autumn of 1948 the longing for the mountains pushed aside all sensible considerations. For the first time since I was twelve years old, I had to do without a summer holiday in the mountains. The safety valve guarding one against exaggerated climbing expeditions was thus removed. Added to this came the great disappointment in my own work. Lured by UNESCO's plans of philosophical research into international ideological conflicts, I had been tied up in Paris for nine months. Such large-scale extravagant schemes prove, however, impracticable. Too much nationalism and too little belief in research prevented UNESCO from getting the number of nations to subscribe to such long term schemes. By the way of compensation, I indulged at night in delightful trips to the Alps. As the situation got worse, this was, however, not sufficient compensation; the material was exhausted. Then my fantasies took me to the Caucasus. Later I had to go all the way to Persia, Afghanistan, Hindu Kush and India, and so I was committed.²⁵

Although Naess's research interests and total view continued to evolve after 1953, the general philosophical approach of the mature Naess, outlined at the beginning of this essay, was basically in place. Naess has described his philosophical work as falling into four periods or phases. From the mid-1930s until about 1940, he focused on philosophy of science. Then until about 1953, he concentrated on empirical semantics. A short period, surrounding the publication in 1968 of his major work on the zetetic scepticism of Pyrrho, ends when, at the pinnacle of his philosophical career, he sought early retirement in 1969 to devote himself more fully to ecological issues and activism. Naess has commented that this effort to be more actively engaged in social and political conflicts reflects his desire "to live rather than function." This view adequately reflects coarse, general trends, but it fails to do justice to Naess's philosophical approach, which has him mine a larger range of topics and return to them in a helical fashion throughout his life. I would rather describe his work as falling into

thematic areas that were picked up, sometimes put on ice, but returned to periodically throughout his life. Although I concur that the period after his formal retirement can be seen as emphasizing ecological philosophy and activism, the two decades between 1960 and 1980 also represent a period of considerable productivity on conventional academic philosophical topics. It was in those decades that Naess produced important work, especially, on scientific and cultural pluralism, Gandhi and Spinoza scholarship, history of philosophy and philosophy education, and normative systems theory. He has written on a wide range of important philosophical topics even into the 1990s and beyond, during which time he produced, among other works, his *Life's Philosophy* (2002; coauthored with Per Ingvar Haukeland), introductions to the philosophy of Gandhi (2000) and Spinoza (1999), and *Introduction to General Relativity and Its Mathematics* (1998; coauthored with Øyvind Grøn).²⁶ An adequate sketch of Naess's subsequent research interests and philosophical development can be gleaned from the following brief discussion of the volumes in the *Selected Works* and the discussion, at the end, of how his earlier work figures into the evolution and exegesis of deep ecology.

Naess's best-known philosophical work is likely *Interpretation and Preciseness*, published in 1953 (SWAN I). It is an attempt to convince the world of analytical philosophy about the types of approaches that are necessary, from the standpoint of a radical empiricist, to adequately interpret terms and point-of-departure statements (T_0 statements), given the manifold of plausible interpretations. It highlights the role and potential of experience in relation to intuition and reflection by requiring that every direct or implied hypothesis regarding the actual use of terms, phrases, or sentences be testable. In addition, it responds to the ostensibly antiphilosophical sentiment in *Erkenntnis* by clarifying the function of and relationship between point-of-departure statements and precizations. In Naess's semantics, the most general statements, T_0 statements (words or sentences), are phrased in ordinary language and are intended to be philosophically neutral. T_0 statements serve as points of departure for investigations of possible interpretations. When a new interpretation of an expression eliminates some of the ambiguity of a preceding interpretation, without adding any new ambiguity, it is said to be a "precization." Thus, a sentence T_1 is more precise than a sentence T_0 when every plausible interpretation of T_1 is also a plausible interpretation of T_0 but at least one plausible interpretation of T_0 is not a

SERIES EDITOR'S INTRODUCTION

plausible interpretation of T_1 . This process of using successive differentiation to better understand people's interpretations of terms, phrases, or sentences can go on almost ad infinitum; it is limited only by time, resources, imagination, and willing test subjects. With this process, however, Naess has created a formal approach for classifying different statements (interpretations) based on users' "depth of intention," the point at which they no longer, explicitly or implicitly, accept or embrace higher levels of precization. A focal point is Naess's approach of directly employing surveys to explore systematically and empirically the meanings of terms, phrases, or sentences based on their occurrences. Naess also created a formal procedure for comparing occurrences, both interpersonal and intrapersonal, that involves performing tests for different forms of synonymy. Naess has applied his empirical semantics approach to explore the meanings of "truth," "democracy," "it is the case," "certain," "perfectly certain," and "extremely probable" (see SWAN VIII for additional details on and applications of empirical semantics).

In *Scepticism* (SWAN II), published in 1968, Naess takes on the generally accepted position that scepticism, if widely embraced, leads to the intuitively false conclusion that we cannot know anything. Naess explores the variety of historical interpretations of scepticism in light of Sextus Empiricus's outline of Pyrrhonian scepticism. Three categories of philosophical positions on the question of truth are considered: Dogmatists claim at least one truth, Academicians negate the possibility of finding any truths, and Pyrrhonists neither assert that they have found any truths nor assert the impossibility of finding one. Naess takes a sympathetic view of this last group, arguing that this form of zeteticism can represent both a viable philosophical position and a way of life that supports positive mental health. What ultimately sets this position apart is not that supporters are fundamentally opposed to making acts of assertion, to stating that "something is the case," but that they do not make such assertions with the conviction of truth. Naess also uses empirical semantics to demonstrate support for this position on rational and epistemological grounds. Distinguishing between one's philosophical view and the necessity of firm, socially responsible action in everyday life, he also responds to the common notion that this radical nondogmatism generally leads to paralysis of action. In the end, Naess argues that adopting this updated view of Pyrrhonic scepticism could lead to quite the opposite, a more open-minded approach to philosophy and life. Further elaborations on particular aspects

of Naess's Pyrrhonism along with a response to Rescher's reappraisal of scepticism appear in SWAN VIII.

Which World Is the Real One? (SWAN III), which was first published in 1969 and revised in 1982, is, in part, an attempt to reinvigorate appreciation and study of the broad variety of philosophical outlooks and total views that exist in Chinese, Indian, Greek, Western, comparative, and recent philosophy. It makes use of Naess's empirical semantics, developed in *Interpretation and Preciseness*, to argue that it is an illusion to assert that combined scientific and philosophical or "purely" philosophical syntheses of such total views can exist. Naess argues that the results of science cannot be integrated into any single world picture, in part because such attempts at synthesis are necessarily fragmentary and because valid multiplicities of syntheses exist. He also takes up the question of the comparability of total views. Such comparisons, although important, are inevitably shaky because, despite admirable aspirations for standing back to obtain a meta-perspective, real people can never totally throw off their own total views; regardless of how explicit those views may be or of how conscious of them their holders are, biases are unavoidable. We always have our own perspective to contend with. For Naess the inevitable conclusion is that pluralism is inescapable and nothing to lament. He combines these points of view with a discussion of cultural anthropology to argue for the critical importance of supporting the flourishing of rich cultural diversity. Additional articles elaborating themes related to the significance of maintaining cultural diversity and its relationship to ecological sustainability appear in SWAN X.

In *The Pluralist and Possibilist Aspect of the Scientific Enterprise* (SWAN IV), published in 1972, Naess suggests that scientific theories must be understood in the wider context of the plural rationalities from which they spring. Science is not autonomous. Nor can it be seen justifiably as arising independently from the general enterprise of building philosophical systems. Furthermore, the relationship of models to reality is always indirect. This volume should be seen as an effort to erode the popular misconception of science as infallible and a viable surrogate for religion, not as an attempt to build a unified theory of science within one system, which Naess had long since rejected. Because no theory can ever be either fully verified or falsified, there exists a significant freedom of choice in both modes of exploration and theories that one can tentatively adopt. The notion of "fundamental theories" is immediately called into question. As the undemon-

SERIES EDITOR'S INTRODUCTION

strated (and often undemonstrable) assumptions upon which theories rest are changed, a huge multiplicity of possibilities for future theory development arises, thus possibly helping to inspire a renewed enthusiasm in science by broadening our concept of rationality and restoring the role of imagination. Articles extending or elaborating on the ideas in *The Pluralist and Possibilist Aspect of the Scientific Enterprise* appear in SWAN IX.

Naess's third book on Gandhi, *Gandhi and Group Conflict* (SWAN V), was published in 1974. This book develops an intellectually rigorous presentation of the theory of *satyāgraha*—the way of militant nonviolent resistance—as a strategy for conflict resolution. This work is a paradigmatic example of Naess's approach to research and writing. As the eminent Norwegian social scientist and peace researcher Johan Galtung has suggested, Naess's 1955 *Gandhis Politiske Etikk* (Gandhi's political ethics)—with Galtung—and his 1965 *Gandhi and the Nuclear Age*, along with his articles that analyze or extend on Gandhi's work (see SWAN IX and X), act as exercises or drafts for this, his major work on Gandhi.²⁷ Using Gandhi's own recorded accounts, Naess explores the norms and hypotheses tacitly employed by Gandhi in his nonviolent campaigns and then uses these to create the first philosophical and logical systematization of Gandhi's approach to militant nonviolence. A careful investigation of Gandhi's two ultimate norms (as interpreted by Naess), "Seek complete self-realization" and "Seek truth," and his belief in *advaita* (nonduality), along with a consideration of their parallels to Spinoza's unity thesis, will reveal interesting insights into Naess own characterization and use of "Self-realization!" as the single ultimate norm of his Ecosophy T. Naess also considers Gandhi's approach to nonviolent conflict resolution in light of contemporary reactions against the use of nonviolence by Frantz Fanon, Malcolm X, Stokley Carmichael, C. V. Hamilton, and Sartre. He then examines Gandhi's ideas and intentions regarding group conflict in light of the ideas and intentions underlying other modern philosophies of conflict, including those of Luther, Nietzsche, Tolstoy, and Jaspers.

In *Freedom, Emotion, and Self-Subsistence: The Structure of a Central Part of Spinoza's Ethics* (SWAN VI), Naess uses symbolic logic to present a formalization and partial reconstruction of a small but important part of the *Ethics*. Spinoza's system is embedded in the seventeenth century and expressed in Medieval Latin. Two of Naess's goals are to bring empirical analysis to bear in trying to interpret and update Spinoza's system and to

make Spinoza's insights more accessible and relevant to contemporary readers. To perform his reconstruction, Naess draws heavily on a small book he produced in 1962, *Equivalent Terms and Notions in Spinoza's Ethics*, which lists and discusses 243 equivalences that are directly asserted or suggested by Spinoza in the *Ethics*, according to Naess.²⁸ Accepting the transitivity of the equivalence relations as a general rule, Naess argues that a vast array of structural relations can be elucidated (many of these are often only suggested or implicitly asserted by Spinoza). One of Naess's key conclusions is that every living thing is to some extent "in itself" and to some extent "in something else" due to the presumed gestalt nature of reality. Another is that the terms *substance*, *attribute*, *God*, *mode*, and *Nature* are "expendable"; Spinoza's basic nondualism is made clearer by Naess. A third conclusion is that *to be active* and *to understand* cannot be systematically distinguished in the *Ethics*. This notion, which has important implications for philosophy of science, is also embedded in Naess's conclusion in *Erkenntnis* that knowledge is cognition—the content of knowledge and the activity of research cannot be cleanly separated. Naess uses his analysis to explicate three main themes of Spinoza's system: the importance of a notion of uncoerced freedom (not coerced by externals), the importance of developing and acting on strong emotions to make progress in achieving higher levels of freedom, and the importance of joy that activates the complete person (as opposed to joy that simply activates part of the body or the soul). By clarifying the semantic structure of a central part of the *Ethics* with his own logical structure, Naess explains that there exists a wide variety of possible interpretations of the contents of the *Ethics*. Articles on Spinoza's determinism and its relationship to freedom, Spinoza and Māhāyana Buddhism, "Spinoza's Finite God," and other Spinoza-related topics appear in SWAN IX. Articles that explore Spinoza as an inspiration for deep ecology appear in SWAN X.

The English translation of *Communication and Argument: Elements of Applied Semantics* (SWAN VII), which was first published in 1966, is largely a popularization of the central ideas in *Interpretation and Preciseness*. The English edition is a somewhat watered-down version (no exercises) of the Norwegian edition that from 1941 to 1969 was used by nearly 100,000 university students in the *examen philosophicum*. Its purpose, to quote the *Times Literary Supplement*, is ". . . to teach people in a democratic society to think clearly, coherently, and above all responsibly." Naess's hope is that teachers use controversial examples from current events—the more emotional the

SERIES EDITOR'S INTRODUCTION

better—to confront students with their own confusion and encourage them to strive for higher levels of depth of intention. The final chapter outlines six “Gandhian” rules of effective discussion, which emphasize avoiding six forms of “irrelevance in discussion.”

The first two volumes of selected papers (SWAN VIII and IX) contain important material that is not covered by the preceding volumes, material that complements them, or material that builds on or reevaluates positions taken earlier. Volume VIII includes sections on “Empirical Semantics and ‘Truth,’” “Zeteticism,” “Empiricism, Possibilism, and Pluralism,” and “Metaphysics, Morals, and Gestalt Ontology.” Volume IX includes sections on “Democracy, Ideology, and Rationality,” “Philosophy of Science,” “The Philosophy of Peace, Gandhian Ethics, and Communication,” “Spinoza,” and “Philosophical Development, Environment, and Education” (which includes an autobiographical article describing key influences in Naess’s philosophical evolution, “How My Philosophy Seemed to Develop” and an interview, “Deep Ecology and Education”). A number of the especially significant articles have already been referred to, where relevant, in the discussion of Naess’s philosophical evolution; other articles are discussed in the notes.

Today, Naess is, perhaps, best known for his “deep ecology” writings, the topic of *Deep Ecology of Wisdom* (SWAN X). This work began with a short unpublished paper written in 1965, “Nature ebbing out” (in SWAN X), and continues to this day. As the primary architect of deep ecology, Naess has more than seventy-five published articles and book chapters and more than sixty unpublished pieces on this topic. His only book-length discussion of deep ecology began with a short mimeograph, *Økologi og Filosofi* (Ecology and philosophy), published in 1971. The fifth revision and expansion of this initial work resulted in the 1976 classic, *Økologi, Samfunn og Livsstil* (Ecology, community, and lifestyle), which has been translated into Swedish, English (1989), Italian, Japanese, and Czech. This book has not been included in the *Selected Works* because it is widely available and currently in print.

Volume X is the first comprehensive collection of Naess’s work on deep ecology—it includes a broad array of articles on its history, influences, theory, development, practice, and prospects. This volume shows how deep ecology represents the integration and culmination of Naess’s lifelong interests in philosophy, social research, activism, science, and nature. It demonstrates how Naess, in his explication and elaboration of deep ecology, draws extensively from both his life experience and his research on empirical se-

mantics, scientific and cultural pluralism, Pyrrhonic scepticism, Spinozistic nondualism and activeness in relation to problems, gestalt ontology, normative systems theory, total views, and Gandhi's concepts of self-realization and nonviolent communication. Volume X also shows how Naess's approach to deep ecology has unfolded over time, with substantial emendation, in part as a response to the worsening ecological crisis, in part to answer criticisms that deep ecology was turning into a cult or religion, and in part to address the considerable confusion and controversy that arose from his use of provocative terminology and philosophical vagueness.

Ever since he coined the term *deep ecology* with his now famous paper "The shallow and the deep, long-range ecology movement: A summary," (in SWAN X) given at the 1972 Third World Future Conference in Bucharest, Naess's central concern has been to use philosophy and philosophical thinking to help humans overcome the ecological crisis and, ultimately, to restore the Earth to a state of rich and flourishing biological and cultural diversity (see volume X). A basic premise is that some ethical norms, particularly those grounded in spontaneous experience, can be tentatively accepted as objectively valid. An example for Naess would be the statement that "Every living being has an equal right to live and flourish, *in principle*." This statement in no way denies that maintaining our existence necessitates killing living beings. Another key premise is that the human potential for caring is not static or limited—it can be both extended and deepened. The ecological crisis is embedded in an ecocultural crisis. Its resolution will necessitate cooperation and collaboration among the peace, social justice, and ecology movements.

Naess does not see himself as "inventing" deep ecology. Rather, he gave a name and a philosophical framework to a minority tradition, a nascent social movement that has been with humanity since at least Buddha, Chuang Tzu, Saint Francis of Assisi, Thoreau, John Muir, and Aldo Leopold, and is epitomized by Marjory Stoneman Douglas's 1947 *Everglades: River of Grass* and subsequent crusade to save the Everglades.²⁹ This movement finally came of age in the contemporary era after Rachel Carson's *Silent Spring*. Naess's work on "deep ecology" can be subdivided into three main thematic areas.³⁰

What I refer to as Naess's deep ecology approach (deep ecology as an ecophilosophical approach) represents his contributions to deep ecology theory—it is essentially an outline of a general philosophy of life, which draws considerable inspiration from Gandhi and Spinoza. The focal points

SERIES EDITOR'S INTRODUCTION

are encouraging ultimate beliefs that support our capacity to identify with all living beings and Naess's general, pluralistic, normative systems-based strategy for assisting individuals in the process of weaving their ultimate beliefs, descriptive and prescriptive premises about the world, ecological science, and philosophy into systematic conceptual structures for relating to the world—ecologically inspired *total views* or *ecosophies*.

His work characterizing and supporting deep ecology as an international, grassroots social and political movement, along with his work entering into the fray, addressing conflicts, implications, and practical applications of the theory, falls into the realm of contributions to the “deep ecology movement.” Supporters of the deep ecology movement are not united by a commitment to deep ecology as an academic ecophilosophy (which they may not be familiar with or embrace), but by their willingness to endorse the eight-point deep ecology platform, prepared by Naess and Sessions in 1984.³¹ Finally, work discussing his personal systematization of a deep ecological total view falls into the realm of “Ecosophy T.”

Naess coined the terms *deep ecology* and *shallow ecology* in 1972 to juxtapose what he regarded as two radically different approaches for problematizing (*Problematisieren*) and responding to the ecological crisis. In proposing the deep/shallow contrast, he made a technical semantic distinction directed at our level of problematizing—the extent to which we can, and do, coherently and consistently trace our views, practices, and actions back to our ultimate beliefs or bedrock assumptions. Naess starts with a premise, which he has investigated empirically, that at the level of their ultimate beliefs, people generally identify with and appreciate nature. He then uses this to argue that many regrettable environmental decisions are made in a state of “philosophical stupor,” in which narrow concerns are confused with, and then substituted for, more fundamental ones.

The “shallow,” currently more influential approach to environmentalism is identified with treating the symptoms of the ecological crisis, such as pollution and resource degradation. This reform-oriented approach is grounded in technological optimism, economic growth, and scientific management, not in ultimate premises that plumb the relationship between people and nature. It thus ultimately fails to address the philosophical, social, and political roots of the ecocultural crisis.

The “deep” approach, on the other hand, while in no way discounting the exigency of addressing pollution and resource degradation, adopts a

broader, long-term, more sceptical stance. Doubtful about technological optimism, critical of limitless economic growth, and decidedly against valuing nature in purely instrumental terms, it asks if the shallow approach's proposed solutions take into consideration the nature of reality and the complexity of the problems its adherents hope to rectify. Stressing the importance of addressing the fundamental roots and coevolving causes of the ecological crisis, deep ecology posits that along with humans' special capacities for reason and moral consciousness come special responsibilities, particularly in relation to the flourishing of nonhuman life and the ecocultural sustainability of the planet.

The deep ecology approach calls for expanding our sphere of concern to all living beings—charismatic or dull, gargantuan or tiny, sentient or not. It acknowledges that every living being has value in itself and views the flourishing of nature and culture as fundamentally intertwined—as part of one reality. This *wide-identification* is characterized by the perception that all life is interdependent; common goals bind all living beings to the life process. In Naess's view one can arrive at wide-identification by drawing on a broad diversity of philosophical or religious ultimate premises, with roots ranging from Christian Stewardship to the Gaia Hypothesis to Naess's own ontologically inspired "Self-realization!" In its most expansive form, wide-identification is the intuition that nature's interests and our own coincide, as with Naess's "Self-realization!"—something akin to a blending of the Hindu *ātman* with a biospherical Pareto-optimality principle. Simply stated, this principle asserts that the increased realization of any individual or species rests on advancing (or at least not hindering) the realization potential of all other individuals or species.

By juxtaposing these two, almost caricatured perspectives, Naess employs a technique of Gandhian nonviolent communication designed to confront core disagreements. The central premise is that society's potential to overcome the ecological crisis rests on guiding discussion and debate to its root causes. One of the primary root causes, Naess asserts, is the widespread disjunction between people's core beliefs and their actions. People, in general, neither comprehend how their practices and everyday lifestyle choices harm the environment, nor recognize how these consequences may be in direct conflict with their core beliefs—this is the primary weakness of the shallow approach. A crucial, underlying hypothesis of the deep approach is that teasing out the presumed inconsistencies between an indi-

SERIES EDITOR'S INTRODUCTION

vidual's actions and his or her fundamental beliefs, while possibly engendering serious ancillary conflict along the way, will ultimately generate progress toward ecocultural sustainability.

Naess contends, as I have pointed out earlier, that humans act as if we have total views whether or not we make such structures explicit. Because our decisions regarding society and nature are guided by our total views, Naess maintains, we *should* attempt to articulate them. By making these structures explicit, we expand both our opportunities for fruitful debate and interchange and our possibilities for creating policies that are consistent with our collective ultimate beliefs. This focus on praxis (responsibility and action) separates the deep ecology approach from more descriptive inquiries into environmental philosophy that focus on axiological questions, such as extending "rights" to certain nonhuman life-forms or grading intrinsic value. The ontologically inspired deep ecology approach attempts to counter the perception of fundamental people/environment and spiritual/physical cleavages. Its primary strategy for overcoming the ecological crisis is to help individuals avoid pseudo-rational thinking.

In relating this notion of persistently asking deeper questions to the ecological crisis, Naess broadens his concept of "depth." In the context of deep ecology as an ecophilosophical approach, depth refers to both the general level of problematizing we employ in seeking out the underlying, co-evolving causes of the ecocultural crisis and the extent of our willingness to consider an expansive array of social and policy responses, even if they necessitate changes that constitute a radical departure from the status quo. Rather than calling for a new environmental ethic or a radical change in fundamental values, Naess's approach to ecophilosophy centers on transforming practice and policy by challenging us to develop more thoroughly reasoned, consistent, and ecologically inspired total views. This work represents a culmination of his effort to integrate reason and emotion. He has created the foundation for a new and promising human/nature relationship that positions humans as plain citizens with special abilities and unique responsibilities and nature as mentor, measure, and partner rather than servant. The current state of global ecological unsustainability has made Naess state that he is optimistic about the twenty-second century but pessimistic about the twenty-first; humans have a long way to go.

Deep ecology has been criticized for being too critical of pragmatic efforts to address acute environmental problems. It has also been accused of

being inherently fascist, antihumanist, antifeminist, and against having indigenous peoples share wilderness areas with nonhuman life-forms.³² As the articles in volume X will show, none of these criticisms are compatible with a sophisticated reading of Naess's writings on deep ecology as an ecophilosophical approach. This is not to suggest that deep ecology as an ecophilosophical approach has clear answers. In inspiring many people to reconsider their value priorities and more consistently relate them to their lifestyles and everyday actions, deep ecology opens more questions than it answers. Three key issues for future research loom on the horizon. First, how can society motivate value priorities for ecological sustainability when individuals do not, on first principles, embrace wide-identification? Second, does taking a deep ecological perspective over a shallow ecological perspective actually result in better policy—policies that lead to long-term protection of cultural and biological diversity, using democratic, noncoercive, and ethically unobjectionable means? Third, how can deep ecology help resolve conflicts in environmental decision making when those conflicts result not from pseudorational thinking but from genuine value conflicts?

Throughout this essay, I have tried to show how Naess's life of rich and varied spontaneous experiences and internal tensions have shaped not only who he is as a person, but also who he is as a philosopher. Viewed separately, Naess's contributions to academic philosophy, social research, and ecological philosophy and activism can appear discordant, dilettantish, and incoherent. When, through careful study of his helical progression, his philosophical and personal maturation, the pattern of the whole unexpectedly reveals itself as a unity, the whole suddenly becomes much more than the simple sum of individual books and articles. With the distance of a meta-perspective, Naess's collective philosophical contributions can be seen as a mosaic—as a superordinate gestalt, in some sense, as a rich and inspiring, but inevitably fragmentary total view. Naess has breathed life back into the study of philosophy by turning its study back to life. With his cultivation of a meta-perspective, a whole, new (old) approach to philosophy and way of seeing the world emerges. This richly patterned mosaic, by encouraging us to celebrate our freedom and affirm life, can help us to reshape our relationship to each other and the Earth in new and promising ways.

Conclusion

It was only as a professor that I became aware of the difficulties of suppressing the significance of the development of feelings in human affairs while at the same time worshipping reason. Both are constantly needed.

Arne Naess, *Life's Philosophy*

The ten volumes of this series (along with a subsequent volume of conversations between Naess and myself on deep ecology and his philosophy) make available for the first time access to the breadth and depth of Naess's philosophical thought. Efforts to judge the significance of Naess's philosophical oeuvre—assertions made in the first sentence of this essay—can now be taken up on an informed basis. When embarking on this process, it may prove beneficial to reflect on Henry Adams's insight on the fundamental limitations of communication, and especially the limits of communicating one's fragmentary total view, "No one means all he says, and yet very few say all they mean, for words are slippery and thought is viscous."³³ Spinoza ends the *Ethics* with the following remark: *Sed omnia praeclara tam difficilia, quam rara sunt* ("But all very clear things are as difficult as rare").

In *The Radical Spinoza*, Wienpahl translates the phrase more literally than usual, rendering *praeclara* as "very clear" rather than the typical "excellent."³⁴ The quest for clarity is painful and difficult as well as amaranthine. The alternative, however, is to abandon joy and freedom and thus meaning. This is the essence of Naess's distinction between being an *academic philosopher* and being a *philosopher of life*, between merely *functioning* and *living*. Drawing inspiration from Spinoza, Naess has cultivated a practice of both integrating reason and emotion *and* transforming negative emotions into positive ones. His challenge is before us and the frontier is long—the choice, however, is ours.

Editorial Approach

Naess has always written books as if they were exercises for himself, tentative formulations that chronicled his views at that very second but were always subject to change. As I indicated previously, many of the prior editions of his books were poorly edited and sparsely documented. Existing bibliographies were incomplete, and indexes (in the rare cases in

which they existed) were always inadequate. Quotations were often transcribed incorrectly and ill-referenced. In addition, the breadth of his work was enormous and sometimes repetitive. Arriving at a plan for a representative *Selected Works* that would have a consistent format and design was no easy task.

All the selections for the *Selected Works* were made in close consultation with Naess. I would prepare recommendations from my master bibliography file and then, whenever we disagreed, we would discuss the pros and cons of the piece and whether it was appropriate for inclusion (this approach proved particularly helpful when we reached the *Selected Papers* volumes). We immediately made a decision to exclude works that were widely available and currently in print. Other important works, such as his dissertation, and his major work on lay people's conception of truth, his work on the semantics of democracy and ideological controversy, and his contributions to history of philosophy were more difficult to exclude, but the nature of the project as a selected works demanded such tough choices. I was encouraged by the fact that Naess often published articles that summarized or updated earlier works. In the end, I was able to reflect a significant portion of the ideas and concepts in these excluded works by including articles of that type in one of the three *Selected Papers* volumes.

The details of editing proved more complex. Much to my chagrin, I very humbly learned how much work goes into a project of this scale and complexity. We decided early on that the level of editing required to bring the prior publications up to the high standards of contemporary academic philosophical publishing would necessitate revised editions. We also decided that since we were preparing revised editions and Naess was alive and could review the work, we would make the role of the editor invisible and not include tedious footnotes chronicling all the changes, however significant they might be. The historical significance, intricacy, and sheer magnitude of *Interpretation and Preciseness* (SWAN I) warranted special consideration. For these reasons, we decided that it would be best to prepare only an edited version for this volume and not attempt a complete revision as with the other volumes. In the early stages of the project Naess and I worked together closely, intimately. In my effort to eliminate errors and to enhance readability, flow, and clarity of argument, I brought Naess question after tedious question when I first embarked on the project (particularly when I was in Norway as a Fulbright Scholar in 1996).

SERIES EDITOR'S INTRODUCTION

After working through several manuscripts, Naess decided to place the remainder of the responsibility for revising and editing the manuscripts in my hands.

We have made our best effort to reconcile inconsistencies, make corrections, and chase down incomplete bibliographic references (in most cases no bibliographies existed for the original works). I regret, however, that some imperfections remain. I am also responsible for any new errors that have been introduced—their existence, unfortunately, is unavoidable. I am, however, heartened by a conversation I had with Naess midway through the project, after he had reviewed several drafts of revised manuscripts. He commented that at least 90 percent of my revisions resulted in improvement and that no significant misinterpretations had been introduced. Given the nature and complexity of this project, that sounded like odds I could live with.

Acknowledgments

A project of this magnitude, by its very nature, represents the labor and love of an entire community. It could never have gotten off the ground, much less been completed, without a fantastic and deeply committed team. I have been blessed by the opportunity to work with, learn from, and receive guidance and support from so many talented friends and colleagues. It's been a wild ride; I owe you all a tremendous debt of gratitude.

First, the inspiration for the *Selected Works* and the majority of its financial support are due to the foresight and generosity of "Miracle Doug," Douglas Tompkins, president of the Foundation for Deep Ecology (FDE). Thanks for your vision, Doug. Quincey Tompkins Imhoff, former executive director of the Foundation (and current vice president of the board), also deserves recognition for her tremendous support during the early years of the project, as do program directors Jerry Mander and John Davis. Special thanks also go to Sharon Donovan, the Foundation's publishing manager, who in the project's final years has guided it through a long and sometimes circuitous path to completion. The Foundation has also always had an amazingly gifted and dedicated staff. At one point or another, many of its staff had a hand in helping this project along—offering assistance at a key point, a kind word, inspiration, or simply good cheer and a smile.

SERIES EDITOR'S INTRODUCTION

Thank you, Denise Wilson, Debi Barker, Esther Li, Lizzie Udwin, Julie Lindow, Miyo Sakashita, and Emily Lydgate.

I was also supported by the Fulbright Foundation with a senior research/teaching fellowship at the University of Oslo's Centre for Development and the Environment and Institute of Philosophy in 1996. Additional support came from Western Michigan University. Special thanks go to WMU's dean of the College of Arts and Sciences, Leonard Ginsberg, and to my chair, Thomas Bailey. My colleagues at Western Michigan University also deserve thanks for their tolerance and succor while I focused all my available energies on this project. I am grateful for their flexibility and generous support. Wil Emmert, one of WMU's Research and Program officers, also deserves a great thanks for his patience and skillful assistance.

The project has been blessed with a distinguished advisory board—Robert S. Cohen, Bill Devall, Alan Drengson, Ingemund Gullvåg (deceased), Per Ingvar Haukeland, Kit-Fai Naess, Nicolas Rescher, George Sessions, Michael Soulé, Douglas Tompkins, and Jon Wetleson. All of the advisers offered significant assistance in one form or another. Bob Cohen graciously shared his expertise and offered invaluable advice, encouragement, and support throughout the project. Bill Devall gave encouragement and helped bring volume X to completion by coauthoring its preface. George Sessions offered advice on the selections for volume X, provided guidance, and carefully reviewed a draft of this introduction. His suggestions greatly improved its flow and clarity. Kit-Fai Naess's tremendous moral support and great assistance in locating obscure documents and preparing bibliographies were invaluable.

Alan Drengson's contribution as a project adviser and in the project's final year as Associate Editor deserves special mention. At a crucial time, when the project was stalled in its later stages, Alan stepped up to the plate and played a key role in helping shepherd the project to completion. In particular, he took over most of the day-to-day project-coordination responsibilities for the final year of the project. He reviewed the copyedited manuscripts for volumes I, VIII, IX, and X, oversaw preparation of the author's prefaces to each volume and the editors' prefaces to volumes VIII, IX, and X, and reviewed the final manuscript proofs. This was not an easy task. I owe Alan a great debt for his fortitude, commitment, and generosity. For his contribution to the difficult and taxing responsibility of over-

SERIES EDITOR'S INTRODUCTION

seeing the final preparation of volume I, he has been credited as its sole editor.

I am lucky to have been supported by two astonishingly capable, committed, and patient project assistants. Kim Zetter played a critical role in getting the project off the ground and keeping it on schedule for the first three years. Later, Barbara Pijan helped steer the project back on track and over some awkward obstacles after it had run off course. Their talent and dedication played a major role in bringing to life the books before you. Thank you, Kim and Barbara, for your stalwart devotion to the project.

The beautiful and elegant design of the series is the work of Tomatsu Yagi and his nephew Akira Yagi. Ralph Fowler played a significant role in executing the Yagis' design and by filling in any missing gaps. Ralph also performed the typesetting for volumes II–VII. The skillful and efficient crew at BookMatters performed the remainder of the typesetting. Katherine Silver handled the Brobdingnagian task of project management on volumes I and VIII–X and the last crucial stages of the project with aplomb, attention to detail, and fortitude.

The bulk of the project's copyediting was performed by the meticulous and supertalented Anne C. Collins, Ph.D., copyeditor extraordinaire. Additional copyediting was provided by Mary Anne Stewart and Kathy Walker. Indexing was performed by the immensely competent Nancy Mulvaney of Bayside Indexing Service, Julie Shawvan, and Leonard S. Rosenbaum. Proofreading was provided by Carrie Pickett.

Ingemund Gullvåg translated *Which World Is the Real One?* Iver Ørstavik provided the translation of "Experts' views on the inherent value of nature." The original editions of Naess's texts were keyed or scanned by the able and efficient crew at AgAccess—David Katz, Karen van Eppen, Jacob Katz, Rachna Boon, and Tim Rice. Additional keying of articles for the *Selected Papers* volumes was provided by Nancy Ropecka and Jane Drengson. Barbara Pijan, d Jones, Tony Hainault, and Debbie Reid deserve thanks for their careful and thorough transcribing of more than thirty-five hours of discussions with Arne Naess. Thanks are also owed to Tim Quick for his help with bibliographic research for volumes I and VIII–X, and to Kelly McKernan for assisting Alan with photocopying and faxing. In addition, a special thanks goes to Robert P. Goldman, Sarah Kailath Professor of Sanskrit and Indian Studies at the University of California Berkeley, for generously and graciously offering assistance on contemporary Sanskrit and Hindi terms.

SERIES EDITOR'S INTRODUCTION

I am grateful to the dedicated and very patient staff at Kluwer Academic Publishing. I am sad that our original editor, the immensely talented Annie Kuipers, who first recognized the importance of this project, did not live to see it come to print. Stephanie Harmon, Annie's replacement, worked closely with me on editorial matters and on finding high-quality recycled paper, cloth, foil, and other materials that meet the strict environmental considerations of FDE. In the final five years, the able and gifted Charles Erkelens was our editor.

Additional advice and moral support were provided by colleagues, friends, and family: Aimee Carroll, Kirsten Coyne, Paul Craig, Neal Goodwin, Byron Hahn, Ladislav Hanka, Alastair Hannay, Anna Leidberg-Miron, Danny Moses, Richard Norgaard, Max Oelschlaeger, Brian Recht, Stephanie Sarvar, Ed Saxon, Geir Michael Sommerhein, Petter Sorum, and Kristin Walstad. Thanks for your efforts to coax me out of the cave.

Special thanks go to d and Reuben for their forbearance and succor. Someday, all too soon, Reuben will recognize that the invisible "work fairies" that were constantly pulling me back to my office don't actually exist. I can't wait.

Most of all, thanks to Arne Naess for placing his trust in me—it's been a gift, something like an extended trudge up to Tvergastein, but without the fresh air and perspective. Taking on this project has been somewhat like receiving Pandora's box as a present—all sorts of ills and plagues reared their heads along the way. I often felt that I was on a never-ending climbing descent in the night. I was always wondering about rappelling off my rope into the abyss.

The SWAN has taken flight, and I have landed on firm ground—I think? In all seriousness, I learned invaluable lessons. The more I worked through Arne's writings, the more open-minded and optimistic I became. I found myself cultivating perspective and looking at the problems and challenges before me with fresh insights. I also found myself responding with more grace and equanimity in my efforts to counteract the numbing effects of contemporary society.

It is strange and ironic, however, that in being the series editor for the *Selected Works* of the father of deep ecology I spent so much time inside, chained to a desk. But this is part of the paradox of working with Arne Naess. I am reminded of one of my favorite poems—Gary Snyder's "Axe Handles." The last few lines read:

SERIES EDITOR'S INTRODUCTION

Pound was an Axe,
Chen was an axe, I am an axe,
And my son a handle, soon
To be shaping again, model
And tool, craft of culture,
How we go on.

And then it makes sense.

Harold Glasser
2004

Notes

1. In writing this essay, I found myself drawing on more than twelve years of friendship with Arne Naess. A simple bibliography could not do justice to describing how this subtle and multilayered gestalt has been formed. My perception of Naess and his work has been shaped by more than thirty-five hours of transcribed conversations between us, countless other conversations, letters, scraps of paper, e-mails, and Arne's copious annotations in my own books and articles. Camping trips, bouldering, hikes, and cross-country skis have also helped inform my understanding of Arne Naess the fiercely competitive, playful, elfin trickster, who springs to life in nature. I have benefited from three extended visits to Norway, including a Senior Fulbright at the University of Oslo's Centre for Development and the Environment and Institute of Philosophy in 1996. I have also spent other stimulating periods of time with Arne in Svalbaard, England, California, and the deserts of Arizona and Nevada. Finally, and probably most important, I have been inspired and forever changed by my own reading and editing of his work. In this regard, both previously published and unpublished materials have been influential in forming my own perspective on Arne Naess the philosopher. One key published source has been Naess's "How my philosophy seemed to develop," in *Philosophers on Their Own Work*, edited by Andre Mercier and Maja Svilar (Bern: Peter Lang, 1983), pp. 209–26 (in SWAN IX). Another source for insightful material on Naess and A. J. Ayer (as well as six of their contemporaries) is a book created from debates by philosophers for Dutch National Television. See, especially, "The glass is on the table: An empiricist versus a total view," in *Reflexive Water: The Basic Concerns of Mankind*, edited by Fons Elders (London: Souvenir Press, 1974), pp. 11–68 (in SWAN VIII). Finally, additional perspective was offered by an article that discusses Norwegian philosophy from the end of the Second World War to just before 1980: Arne Naess

SERIES EDITOR'S INTRODUCTION

and Jon Hellesnes, "Norway," in *Handbook of World Philosophy Since 1945*, edited by John Burr (Westport, CT: Greenwood Press, 1980), pp. 159–71.

On some of the fine points of this essay, I have benefited from extended conversations with my colleague and old friend George Sessions. I have also profited, over the years, from the significant literature that has been created to shed light on Arne's life and work. Many of the ideas and thoughts introduced in this essay—drawn from my own firsthand experiences with Arne—can also be found in these sources. In many cases, issues only touched on here are taken up in much more detail in those sources. Five key references for historical material on Naess and the evolution of his philosophical approach are identified below (two of which are videos). A wealth of additional material is available in the five festschrifts for Naess (see details in note 15 below). The first of the festschrifts, *In Sceptical Wonder: Inquiries into the Philosophy of Arne Naess on the Occasion of His Seventieth Birthday*, edited by Ingemund Gullvåg and Jon Wetlesen (Oslo: Universitetsforlaget, 1982), contains the most thoroughgoing analyses and critiques of Naess's earlier philosophy that I am aware of, and many of the articles have insightful responses by Naess.

Books

Warwick Fox, *Toward a Transpersonal Ecology: Developing New Foundations for Environmentalism* (Boston and London: Shambhala, 1990). See, especially, chapter 4, "Arne Naess and the Meanings of Deep Ecology."

Ola A. Hegdal and Tore Strand Olsen (illustrator), *Jeg, Arne Naess: Et Tegnet Liv* (Arne Naess: A cartoon story of my life) (Oslo: Kagge Forlag, 2001). A unique and insightful look at Arne's life, based on an idea from Arne's wife, Kit-Fai.

David Rothenberg, *Is It Painful to Think? Conversations with Arne Naess* (Minneapolis: University of Minnesota Press, 1993).

Videos

Crossing the Stones: Arne Naess (Oslo: Norwegian Broadcasting Corporation, 1991), 47 minutes.

The Call of the Mountain: Arne Naess and the Deep Ecology Movement (Amsterdam: ReRun Produkties, Postbus 93021, 1090 BA, 1997), 50 minutes.

2. On Naess's effort to expand the concept of reason to incorporate emotions and feelings, see Arne Naess with Per Ingvar Haukeland, *Life's Philosophy: Reason and Feeling in a Deeper World*, translated by Roland Huntford, foreword by Bill McKibben, introduction by Harold Glasser (Athens and London: University of Georgia Press, 2002). As a testament to Naess's interest and influence in Norway, I note that in a country of about 4.5 million people, 150,000 copies of the Norwegian edition of *Life's Philosophy* have been sold. For a fine example of Naess's use of mythopoetics, see Arne Naess

SERIES EDITOR'S INTRODUCTION

and Johann Brun (photographer), *Det Gode Lange Livs Far: Hallingskarvet sett fra Tvergastein* (The good, long life's father: Hallingskarvet from Tvergastein) (Oslo: N. W. Damm and Son, 1995). For other examples, see Naess's article on Tvergastein, his "Letter to the King of Nepal," and some of his writings on deep ecology in volume X of the *Selected Works*.

3. Most of these questions were drawn from Naess's discussion with Sir Alfred Ayer on the nature of philosophy and the problems it seeks to address (Naess and Ayer, "The glass is on the table," p. 14).
4. See Naess's "Ecosophy and gestalt ontology" in SWAN X.

SERIES EDITOR'S INTRODUCTION

- 9 (Spring 1992); Rana P. B. Singh, ed., *Environmental Ethics and the Power of Place: Festschrift to Arne Naess* (Varanasi, India: National Geographical Journal of India, 1994); Nina Witoszek and Andrew Brennan, eds., *Philosophical Dialogues: Arne Naess and the Progress of Ecophilosophy* (Oslo: Centre for Development and the Environment, 1997; Lanham, MD: Roman and Littlefield, 1998); Andrew Light and David Rothenberg, eds., *Arne Naess's Environmental Thought*, special edition of *Inquiry* 39 (June 1996).
16. Arne Naess, *Four Modern Philosophers: Carnap, Wittgenstein, Heidegger, Sartre*, translated by Alastair Hannay (Chicago: University of Chicago Press, 1968). In the 1970s, philosophy was still influenced by the events of the Second World War. Heidegger's flirtation with National Socialism and the Hitler regime, and his unusual way of expressing himself, made it difficult for him to be considered a great philosopher. Naess's book on four contemporary philosophers was seen as unique because he interpreted in a scholarly and positive way both Heidegger and the fiercely anti-Heideggerian philosopher Rudolph Carnap, a logical empiricist. Carnap, who was forced to flee Nazi Germany, could not fathom how Naess, as an old friend, could present positive discussions of Heidegger and himself in the same book. The other two philosophers included in the book, Wittgenstein and Sartre, also held completely incompatible views of philosophy, but Naess accorded them equally high positive appreciation.
17. For example, works by Naess that are still in print, such as *Ecology, Community, and Lifestyle: Outline of an Ecosophy*, translated and edited by David Rothenberg (Cambridge: The University Press, 1989), and *Life's Philosophy* (2002; see note 2), were not included, for obvious reasons.
18. In "How my philosophy seemed to develop," p. 215, Naess mentions the particularly strong impression, the magnificent expansion of his own "life's frame of reference," made by H. G. Wells's early popularization of the history of life, *Outline of History* (New York: Macmillan, 1920).
19. For detailed discussions of Naess's assessment of logical empiricism, see Arne Naess, "How can the empirical movement be promoted today? A discussion of the empiricism of Otto Neurath and Rudolph Carnap," in *From an Empirical Point of View: The Empirical Turn in Logic*, edited by E. M. Barth, J. Vandormael, and F. Vandamme (Gent, Belgium: Communication and Cognition, 1992), pp. 107–55 (in SWAN VIII). (The original German version of Naess's article, "Wie Fördert Man Heute die Empirische Bewegung? Eine Auseinandersetzung mit dem Empirismus von Otto Neurath und Rudolph Carnap," was written during 1937–39.) For Naess's experiences attending the Schlick seminar, see Arne Naess, "Logical empiricism and the uniqueness of the Schlick seminar: A personal experience with consequences," in *Scientific Philosophy*, edited by Friedrich Stadler (Dordrecht: Kluwer Academic, 1993), pp. 11–25 (in SWAN VIII).

SERIES EDITOR'S INTRODUCTION

20. Naess, "How my philosophy seemed to develop," p. 222.
21. See Arne Naess, *Erkenntnis und Wissenschaftliches Verhalten* (Knowledge and scientific behavior or, more colloquially, Science as behavior), Inaugural Dissertation (Oslo: Norwegian Academy of Sciences, 1936).
22. John Dewey, "Experience, knowledge, and value: A rejoinder," in *The Philosophy of John Dewey*, edited by P. A. Schilpp (Chicago: Northwestern University Press, 1939), p. 597, as quoted in Wallace I. Matson, *A New History of Philosophy*, vol. 2 (San Diego: Harcourt Brace Jovanovich, 1987), p. 454.
23. Naess, "How my philosophy seemed to develop," p. 223. For more details, see Richard McKeon and Stein Rokkan, eds., *Democracy in a World of Tensions* (Chicago: University of Chicago Press, 1951). Naess, as the scientific leader of the project, was viewed as a UNESCO administrator; he was only credited as being the author of the questionnaire itself and the summary paper, although he was intimately involved with the project at all levels.
24. Naess went on to perform a reconnaissance of Tirich Mir (25,263 feet) in the Hindu Kush in the summer of 1949. He then led the successful Norwegian first-ascent team in 1950. The expedition, which included botanical and geological assessments of the region, is chronicled by the team members in Naess et al., *Tirich Mir: The Norwegian Himalaya Expedition*, translated by Sölvi and Richard Bateson (London: Hodder and Stoughton, 1952). Naess successfully pursued a second, vastly more technical expedition to Tirich Mir in 1964. His "The south wall of Tirich Mir East," *Himalayan Journal* 26 (1965): 97–106, discusses this expedition and includes interesting commentary on expedition philosophy and climbing ethics. The article appears in SWAN X, along with other papers on Naess's relationship to mountains and views on mountaineering.
25. Arne Naess, "Reconnaissance, 1949," in *Tirich Mir*, p. 22.

SERIES EDITOR'S INTRODUCTION

29. For a discussion of nonanthropocentrism as part of an ongoing historical tradition with ancient roots, see George Sessions, "Ecocentrism and the anthropocentric detour," in *Deep Ecology for the Twenty-First Century*, edited by George Sessions (Boston: Shambhala, 1995), pp. 156–83. For details on Douglas's effort to save the Everglades, see Marjory Stoneman Douglas, *The Everglades: River of Grass*, rev. ed. (Sarasota, FL: Pineapple Press, 1987).
30. See Arne Naess, "The shallow and the deep, long-range ecology movement: A summary," *Inquiry* 16 (1973): 95–100 (in SWAN X). For a more detailed, mature version of deep ecology, see Naess, "The deep ecology movement: Some philosophical aspects," *Philosophical Inquiry* 8 (1986): 10–31 (in SWAN X). For a concise overview of deep ecology that chronicles its key evolutionary changes and identifies the distinctions among the "deep ecology approach to ecophilosophy," the "deep ecology movement," and Naess's "Ecosophy T" (a particular deep ecological total view), see Harold Glasser, "Deep ecology," in *International Encyclopedia of Social and Behavioral Sciences*, edited by Neil J. Smelser and Paul B. Bates (Oxford: Pergamon, 2001), pp. 4041–45. For a detailed discussion of deep ecology as an ecophilosophical approach with special attention to its policy implications and a discussion of deep ecology's relationship to Naess's earlier philosophical work, see Harold Glasser, "Naess's deep ecology approach and environmental policy," *Inquiry* 39 (1996): 157–87 (reprinted in Witoszek and Brennan's *Philosophical Dialogues*).
31. For anthologies on the deep ecology movement, which include articles by Naess and other deep ecology supporters, see George Sessions, ed., *Deep Ecology for the Twenty-First Century* (Boston: Shambhala, 1995), and Alan Drengson and Yuichi Inoue, eds., *The Deep Ecology Movement: An Introductory Anthology* (Berkeley, CA: North Atlantic Books, 1995).
32. Naess rarely responds directly and definitively to these criticisms—this is not his nature. Siri Naess, however, made an interesting effort to explore the potential of using Naess's Ecosophy T as an inspiration for a feminist normative system in her "Self-realization," in *In Sceptical Wonder*, pp. 270–81. She concluded that while Ecosophy T and her System F have much in common, Ecosophy T goes further by extending to all living beings its concern for activeness and creativity in relation to problems, egalitarianism, and support of the suppressed and exploited.

Author's Introduction to the Series

At ninety-two it is a great honor to be still alive and to witness the publication of my selected works in English. Few philosophers have their work published in a series, fewer still receive this honor before they die. When I was originally approached with the idea of publishing my complete works, I was overwhelmed and overjoyed, but added that not all my books and articles were important enough to merit such an honor. Selected works? Yes, and I am extremely grateful for this initiative and the final result, which presents a representative selection of my work from the earliest to the most recent. [*The Selected Works of Arne Naess* are hereafter referred to as SWAN.]

My interest in philosophy began with Spinoza's *Ethics*, which as a seventeen-year-old I was fortunate to read in Latin. I appreciated Spinoza's grand vision and trusted him implicitly as a person. I accepted that human beings could, and should, have a general outlook with the grandeur of Spinoza's, but I recognized that our individual views on this grand scale will not be identical. Through the years I have realized that there is a splendid variety of interpretations of Spinoza (SWAN VI and IX). His texts are exceptionally rich. As the years have gone on, I have focused on how he leads us to realize we can increase our freedom and sense of connection with the world through strengthening and intensifying our *positive* emotions. For example, loving and caring for our place and others leads to an expansive sense of being part of a much larger world. Emphasizing hatred and anger, on the other hand, makes us feel smaller and isolated from the world. Spinoza, as I interpret him, would express this by saying that "We are as large as our love." Increasing our freedom as human beings leads us toward life in communities colored by friendship, sharing joy and sorrow.

AUTHOR'S INTRODUCTION TO THE SERIES

Before I left gymnasium [the end of secondary education] the headmaster asked me, "What do you intend to be?" My immediate answer was "A philosopher." In fact, I had already conceived of myself as one. I viewed the writings of many contemporary philosophers that I was familiar with, however, as vague and airy and certainly not as inspiring as Spinoza.

My doctoral thesis in philosophy of science was an effort to remind us that in science the content of a theory is not independent of research behavior—the activities of observing, confirming, disconfirming, and so on, and that these are set within a deep context of place, history, and culture. Later, as a postdoctoral researcher at the University of California at Berkeley, I studied the behavior of experimental psychologists doing animal research.

In 1934 and 1935 I studied in Vienna and while there became a member of the famous Schlick seminar, the main discussion group of the Vienna Circle. Their quest for clarity and cordial cooperation in pursuit of knowledge led me to appreciate that "What do I mean?" is an open question. I concluded that we never intend to express anything extremely definite, even in mathematics or symbolic logic. I saw the importance of using empirical methods to find out how we actually use certain expressions and sentences. I developed and applied a wide variety of such methods, which became part of the core for the empirical semantics that runs through my work. I continued to do this type of research into the 1990s, my last project being one in which I questioned experts and policy makers about their ideas of values intrinsic to the natural world (in SWAN X).

In one of my earlier studies, I reviewed about 700 articles from philosophers concerning their use of the word *truth*. For the most part, I found these unconvincing and soon started on empirical studies of the use of *truth* among ordinary nonprofessional people and schoolchildren (in SWAN VIII). Many philosophers seemed to assume that ordinary people hold very naive views about these deep matters. I found through research that, on the contrary, the views articulated by these "ordinary" people were every bit as sophisticated as those held by professional philosophers. This reinforced my conviction that, generally, we greatly underestimate ourselves. Much academic philosophy was narrowly focused and abstract. Philosophers who elicited interest in wide-ranging issues of practical and global importance, such as nonviolence and social justice, have in my lifetime said things that were considered creative, but often too far out. In

AUTHOR'S INTRODUCTION TO THE SERIES

spite of consistent proclamations that science neither would nor could take over all the problems discussed by philosophers, I tried to argue in ways that reminded readers of science done as open inquiry, and I tried to emphasize that it is occasionally necessary to perform empirical research to illuminate or support a philosophical viewpoint.

My empirical and historical research led me to realize that there are no certainties and that there is a great diversity in our spontaneous experience as well as endless ways to describe and appreciate the complexities and values of the world. Thus, I realized that I am one of those lifetime seekers that the ancient Greeks called a *zetetic* (see SWAN II and VIII). From my research on scepticism and the foundations of science and logic, it became clear to me that pluralism (every event has many descriptions and possible outcomes), possibilism (anything can happen), and a healthy scepticism (always seeking the truth but never claiming it) make up the most consistent approach to respecting the perspectives and experiences of others, human and nonhuman.

From my empirical studies of semantics, and from my knowledge of several languages, I came to appreciate the complexity of communication. Being committed to Gandhian nonviolent communication, I saw the importance of avoiding dogmatism and fanaticism. One of the most important discoveries coming from this research, leading to the publication of my major book, *Interpretation and Preciseness* (SWAN I), was the insight that we cannot avoid values in any field of endeavor or research. There are no value-free inquiries or theories. Even if we refuse to express our values, this is itself an expression and choice of values. We must, therefore, be clear about our value choices and try to make them explicit. The choices we make, as Spinoza pointed out, shape the quality of our lives, and values emphasizing positive emotions or feelings are expansive and lead to our growth. We must become ever more aware of our choices and the values involved. Even pure logic assumes certain norms. Empirical research can shed light on these matters. My colleagues in philosophy often found my empirical work perplexing. I, in turn, grew to underrate the necessity of visiting great centers of philosophy, as I preferred to be close to or in the mountains.

When I visited the United States, it was mostly to climb in the mountains or walk and camp in the desert. On one fortunate visit, I dropped in at the graduate students' discussion room at Harvard.

AUTHOR'S INTRODUCTION TO THE SERIES

Speaking with students who were writing their doctoral theses in philosophy, I understood that my knowledge of contemporary philosophy, and of recent important contributions in its various fields, was narrowly limited to special themes of lively personal interest. Even in later years, the tendency to take personal inclination very seriously colored my contribution to the philosophical literature. As can be seen, though, from the titles in these *Selected Works*, my strongly felt interests span a rich variety of fields, philosophical traditions, and movements.

Since childhood I have experienced an intense joy in being together with animals and plants and in contemplating the immense evolutionary development of life on earth over millions of years. From an early age I also developed an intense love for mountains and for being in them. Much of my creative philosophical work was done at Tvergastein, my mountain hut in Norway (see SWAN X). My devotion to outdoor life is in the Norwegian tradition called *friluftsliv* (literally, free-air-life). In many respects, I approached philosophical and cross-cultural studies as if I were a field ecologist or naturalist. It was against this background that my work from the 1960s onward focused with close attention on cultural diversity, biodiversity, sustainability, and the deep ecology movement.

My work since the Second World War has been increasingly within movements such as those furthering social justice, peace, and ecological responsibility. During the war, I engaged in anti-Nazi activism, and from that time also in promilitant Gandhianism, a nonviolence that is not pacifist in the usual sense but insists that if it is a bloody fight for justice against injustice, we seek "the center of the conflict" and, if necessary, cooperate with people who use arms. During the Cold War, I participated in the "third side," against both communism and extreme anticommunism, for example, as the scientific leader of a UNESCO project bringing Marxist and anti-Marxist politicians and political science researchers together in an unbiased discussion of the essence of democracy and freedom. Some of the relevant publications are included in SWAN IX.

The broad spectrum of books and articles included in the *Selected Works* represents, in many ways, a chronicle of my passions and influences. The *Selected Works* record, albeit in an inevitably fragmentary way, one possible expression of these. My dream and hope is that some readers will be inspired by their sheer variety, and that young philosophers will be encouraged to let strong personal motivations steer their studies.

AUTHOR'S INTRODUCTION TO THE SERIES

Working habits vary. Some people write an article and go on to the next without looking back on the old one; others come back from time to time, radically revising and changing the old one. The latter is my way of working. Lecturing in many places about these subjects, I have found it natural to revise the old manuscripts until sometimes very little is left of the original. Therefore, I have always viewed my writing as preliminary; a year, five years, ten years after publication of the first editions I have itched to revise, *thoroughly* revise them. When my first book was printed in 1936, I went to watch the hulking presses printing out one page at a time. I was terrified, thinking of mistakes or some awkward sentences being duplicated again and again.

When I was offered the opportunity to have a selected-works series published, I immediately thought I would like to review all my work and ask how, from today's perspective, I might answer the difficult questions I had earlier attempted to probe. Such a task would have been a particularly difficult proposition, because although many of my books and articles contain new ideas, the ideas are often not developed as well as I might have hoped. But alas, I am saved—at my age there is not time for me to accomplish such a comprehensive reevaluation of my work; I do not even have the capacity to do it now in any case.

Who could contemplate undertaking a publishing project of such ambitious proportions? Douglas Tompkins, mountaineer, entrepreneur, protector of wilderness in Chile and Argentina, and creator of the Foundation for Deep Ecology, is such a person. "Miracle Doug," as I call him, likes the idea that the deep ecology slogans and the deep ecology approach were introduced by a philosopher. I am grateful to him for his firm conviction, inspiration, and great generosity. My gratitude, however, extends well beyond my thanks to Doug, to others who have supported and championed this project.

Quincey Imhoff, when executive director of the Foundation for Deep Ecology, supported SWAN with generous grants and other contributions. SWAN has also benefited from faithful assistance and cooperation in the preparation and editing of the manuscripts. The late Professor Ingemund Gullvåg prepared the initial translation of *Which World Is the Real One?* (SWAN III). Professor Alastair Hannay translated the first edition of *Communication and Argument* (SWAN VII) and offered invaluable suggestions for improving the readability of the first editions of *Scepticism*

AUTHOR'S INTRODUCTION TO THE SERIES

(SWAN II), *The Pluralist and Possibilist Aspect of the Scientific Enterprise* (SWAN IV), and *Gandhi and Group Conflict* (SWAN V).

Most of all, however, I am grateful to Harold Glasser, the series editor, and his assistant, Kim Zetter, who oversaw all aspects of the project from design to production. Glasser's unique combination of intellectual tenacity, attention to detail, mastery of my work, and cooperative spirit made him a natural to take on the monumental task of selecting and editing my works. Glasser not only labored to improve the English and clarity of each manuscript, but his keen ability to ferret out countless technical and pedagogical errors has resulted in substantial new editions of volumes II–VII that are both far more comprehensible and accessible than the originals. I thank him for his valiant work on this project, both during his stay in Norway as a visiting Fulbright professor, where we collaborated on a strategy for revising the previously existing material, and in the subsequent years it has taken to complete the project.

From the beginning of the SWAN Project in 1994, Alan Drengson has encouraged and helped to move this work forward in numerous ways. Especially in the last crucial stages of completing volumes I, VIII, IX, and X, his help and editorial oversight have been invaluable. Thanks for his devotion, good humor, and positive enthusiasm. Thanks to both Drengson and Tim Quick for their extensive bibliographic research. Thanks to Bill Devall for his support and encouragement and especially his help on the completion of volume X, *Deep Ecology of Wisdom*. Thanks to Anne Collins for her outstanding work as the copyeditor of the SWAN volumes. Thanks to George Sessions for his support and encouragement.

Last, but certainly not least, immeasurable thanks go to my wife, Kit-Fai Naess, who has worked beside me throughout the years to provide invaluable assistance, encouragement, and inspiration.

Arne Naess

2004

Author's Preface to This Edition

As soon as you start a scientific research project, a philosopher of science might interrupt you by saying, "Very interesting that you have implicitly made certain assumptions. . . ." You admit this, but defend yourself by saying that most of the assumptions can be tested, if deemed necessary. Naturally, the validity of the tests rests on further assumptions. The conclusion of an investigation may have the form "If the assumptions a_1 , a_2 , . . . a_n are all correct, *then* such and such." When you negate or change one or more *basic* assumptions, you will get different total views. The scientific enterprise, including the Western and the classic Chinese and Indian, is a part of a culture. So is the above sentence and so is this one. There are always "presuppositions" in such undertakings, as R. G. Collingwood noted.

Both the pluralism and possibilism advocated in this book (SWAN IV) are motivated by feelings of claustrophobia that arise in me when I read about what science is "supposed" to be. There is too little room for the function of the wild imagination. I agree with the statement "In the wild is the salvation of humanity." The wild has in many ways reemerged with the demise of the view that a rigid form of determinism was assumed and shown by science. What has become apparent is that anything can happen (possibilism), and that the world we know through experience is incredibly rich and can be described in inexhaustible ways. Our spontaneous experience is rich and diverse, as is attested by the many languages and cultures in the world. This is one reason I am a pluralist with respect to the scientific enterprise. Science as wondering and inquiring is open-ended in many ways, but science as an enterprise is a social institution with many restrictions. Studies of science and culture have led us to see that openness and creativity are basic features of natural systems and human life.

AUTHOR'S PREFACE TO THIS EDITION

The latest conceptual cage some of us have run into is that offered by Thomas S. Kuhn. It arises from the historiography of science in general. Sentences like “The history of science shows that . . .” can only express knowledge in the form of “If we assume such and such, we may validly say that the history of science *shows* such and such.” However, science as a complex enterprise is not a showcase. Moreover, as soon as you start to change any of the undemonstrated assumptions, new possibilities are seen, and then history looks different. You do not escape assumptions, but rather you live through a variation of them in a discontinuous way. You need not agree with me here. If you have time and energy, you can instruct me about some interesting assumptions I make in saying this. I might then afterward reveal some of your assumptions when you were talking about mine.

Arne Naess

2004

Author's Foreword to the First Edition

The motive for publishing the present study springs from numerous encounters through many years with people who feel coerced by “scientific results” to change their personal philosophy. They look on science as a vast machinery that produces correct views and opinions in a sort of vacuum—completely independent of its setting in a society or of the interests, motives, or purposes of those who attend to the machine, oil it, serve it, improve it, spoil it, or neglect it. There is, in fact, no such machine. More specifically, the scientific enterprise is *not* independent of the philosophic or general system-building enterprise. Only insofar as a person is autonomous and articulate enough to have value-priorities, action-priorities, ontological priorities, or views, do scientific results have a *rational* power of influencing—even drastically changing—attitudes, however basic. Only under such circumstances do the neat sentences expressing results of scientific research become sufficiently “juicy” in meaning to touch, in a rational manner, on personal situations. Otherwise, the influence is irrational—a kind of coercion, due to passivity, indifference, or simply crude misconceptions about the nature of scientific knowledge.

There is, in my view, no “scientific” worldview, no established scientific “knowledge” in senses current among those people I am talking about. Consequently, their efforts at personally creative world orientation should not be hampered by science. On the contrary, they should be able to make use of, and participate in, science—provided they “know who they are” to the extent of having at least provisionally articulated their basic priorities of valuation and action.

Because at a given time in a definite society only one or a small number of views on a certain topic are considered “respectable” scientifically, the coercion acts in the direction of conformity, spurious agreement, and

AUTHOR'S FOREWORD TO THE FIRST EDITION

other-directedness; in short, its effect is strongly impersonalizing and dehumanizing.

The sterility of the scientific enterprise in providing a worldview does not make it less interesting. On the contrary, many who turn their back on scientific activity do so through a misunderstanding and lose an invaluable opportunity for participating in a central human undertaking—indeed, one that in the long run may prove to be *the* collective enterprise of this remarkable species.

I have no great confidence in my ability to convince others of the tenability of the views put forth in this work. I feel I should stress, however, that only very special aspects of the total scientific enterprise are to be considered, namely its capacity for surprise, for unlimited novelty, and unlimited diversity of interpretation. Science has many other aspects, some of which may give the impression of inescapable, lawful development, necessity, and inevitability. It is the aim of history of science, according to one of the many legitimate conceptions of historical research, to make us “understand” that science *had* to develop exactly as it did, given the social and other forces operating at each moment. But it so happens that this monistic and totalitarian aspect is *not* the one I deal with in what follows.

With regard to the preparation of this book, I have many thanks to extend to the people who assisted me in the undertaking of this project. I am especially grateful to the Norwegian Research Council for Science and the Humanities for supporting my enterprise in its various phases since 1958, to Magisters Øyvind Baune and Nils Roll-Hansen for persistent discussion on how to make the central ideas clear, and to Dr. Alastair Hannay for invaluable assistance in making the manuscript readable to an English-speaking public.

I

The Impact of the New Historiography of Science

The Neat Image of Science

The general view of science in Western societies has been heavily influenced by certain opinions about the nature of scientific development and progress. These opinions may be briefly indicated as follows:

1. The mature sciences, such as physics and biology, are *autonomous*. Even if to some extent they answer questions within philosophical or other “nonscientific” traditions, they have now emancipated themselves for good. Philosophers may do “philosophy of science,” or better, “logic of science,” but not mix science and philosophy, neither extrapolating scientific results, like Herbert Spencer, nor crudely basing their semantical arguments on experimental evidence, such as I do. To mix science and philosophy is to succumb to a “category mistake.” There is, and must be, a discontinuity between the two.
2. The process of justification, testing, and validation of scientific theories, hypotheses, laws, and observational journals is a *rational process* to be carefully distinguished from the more erratic pragmatics and heuristics dealing with favorable conditions for discovery and invention of theories. Certain stateable, coherent rules dominate science in its supreme form—that of the systematics of science—as manifested in any authoritative advanced textbook. Scientific rationality is autonomous.
3. The sciences are *accumulative*—facts being added to facts and new, more comprehensive, and accurate theories being substituted for old ones. Theories tend to grow less different, less mutually inconsistent, and more comprehensive. This leads in the long run to a *unification* of science.

4. There is a parallel process of step-by-step *approximation to truth*. Although it cannot be directly tested, we are at least to assume there is a process of increasing confirmation, corroboration, and exactitude, sometimes expressible by increases measurable in terms of probability or certainty.

There are also discoveries that certain phenomena are physically, biologically, and so forth, impossible, adding up to an *a priori* part of science. The rest never reaches absolute certainty but attains higher and higher degrees.

As a result of this (very roughly indicated) image of science, combined with the tendency to accept that philosophical reflection is a kind of reflection *sui generis*, using logical analysis and leaving empirical investigations to the sciences, the education of professional philosophers does not generally include practical training in any science (except formal ones). This in turn strengthens the tendency to mutual noninterference and the tendency to underrate the extent to which science must be understood as a way of *doing* things. The noninterference also covers the philosophizing of scientists in what are generally considered naive “excursions” by professionals.

Compared with the history of art, religion, economics, or politics, the above image of the history and growth of science is conspicuous for its neatness or narrow rationality.¹

The New, Gaudy Image of Science

One of the first prominent historians to enter the field of history of science after World War II² characteristically opens the introduction to his lectures as follows:

Considering the part played by the sciences in the story of our Western civilization, it is hardly possible to doubt the importance which the history of science will sooner or later acquire both in its own right and as the bridge which has been so long needed between the Arts and the Sciences.

Perhaps in part as a result of the obvious influence of scientific research on the main development of warfare, one could discern in the postwar years a craving for a deeper understanding of science in its rela-

tion to general history and to modern industrial civilization. In particular, the intensive study of the history of science by professional historians or scientists with genuine historical training brought forth a wealth of astonishing details and new points of view.³

A revolutionary movement has started that still seems to be gathering momentum. With some simplification, one may speak of a *new, gaudy image* of science, stressing the human side of a human enterprise, and thus we find the rapidly expanding fields of history of science forming the main bridge between “the two cultures.” These fields provide a strong appeal to researchers in the humanities and even to professional writers such as Arthur Koestler.⁴ The development of science has become a colorful drama!

Impact of the New Image on Philosophy: Typology of Total Views

Aspects of the new image of science have already influenced philosophical research in some ways, but I suppose the main impact is still to come. In what follows, certain conclusions on how to conceive the dynamics of scientific thinking, including efforts of validation and justification, are formulated, but only insofar as they have important relations to certain philosophical positions in epistemology and ontology.

The examination is therefore far from neutral in choice of topics. I have had certain philosophical conclusions in mind during most of the argumentation. One of these conclusions is that sciences, when articulated with care, are like fragments; they constitute the most exactly formulated and interpersonally testable parts of existing, or more often potential, general views about man and the universe. Efforts to isolate “pure science” have failed and will continue to fail. Scientific revolutions, or more generally, any considerable change in scientific tradition, makes science (represented by the small elite of creative scientists) shift loyalties within the area of general (near-total) views.

History of philosophy, history of ideas, and contemporary philosophical movements furnish the most comprehensive examples and studies of general views. Philosophers who have been trained as scientists are able to make more explicit, broader frameworks of contemporary science and help work out *typologies of general views* with the ultimate aim of covering any

possible coherent total view, irrespective of whether it happens to fit in with the views dominant among the scientists of the contemporary scene. Facing the uniformities of technological civilization, the typologies serve ecological balance and diversity.

I say “typologies” rather than “typology” because the choice of categories or principles of classification (*fundamenta divisionis*) will be to some extent arbitrary. When near-total views comprise logic, methodology, and other basic fields of argumentation, their common ground, as far as it is articulated and conceptualized, diminishes, and therefore also the import of a critique of one of them based on any other. Near-total views may be considered to be valid, if coherent.

These preliminary remarks are intended simply to make it more understandable why I have selected below only certain topics for lengthy treatment and have skipped others altogether.

Claims of Refutations and the Historian: Echolalia or Critical Attitude?

As an example suggesting the direction in which the new historiography is moving, we shall discuss refutation and refutability.⁵

In describing scientific developments, part of the job of the historiographer consists in understanding and interpreting certain happenings referred to by scientists themselves in such proclamations as “theory *x* has now been *refuted*,” “this law must now be considered *established*,” or “my hypothesis is now *verified*.” The historian cannot presume that “refute,” “establish,” or “verify” mean the same to these authors as they do to himself.

Various historical questions apply to all descriptions of a theory’s loss of status. Exactly what was the relation between the theory and the *x* said by scientists or historians or both to falsify, refute, weaken, and so forth, the theory? (A relation of derivation? If so, what kind? Or perhaps a looser connection?)

Regarding the *x* itself, we find reference not only to “observations,” but to “facts,” “phenomena,” “laws,” and to other theories conceived to have been verified and now *believed* to be inconsistent with the theory or doctrine undergoing testing. The image of refutation as a simple “confrontation of theories with observation” is clearly not one that can be derived from a study of the scientific literature of the last centuries.

The disagreements among creative scientists as to the exact status of a theory at any given time makes it impossible for the historiographer to adopt the rule that a theory is refuted when a scientist with a solid reputation *in his community* says so. Application of such a criterion would often require us to announce a theory to be both refuted and not refuted, verified and not verified, established and not established, within one and the same time interval. But what of a rule telling us that a theory is refuted when *all reputable scientists who have recorded their opinion* say, or imply, that it is? This rule may be considered part of a comprehensive set of rules covering a vast number of happenings considered as normal features within scientific development itself. The rules may be roughly formulated and summarized as follows: when a presumably competent scientist says “*x* has now happened” and *x* is a normal part of the scientific enterprise proper, *x* *has* happened, and the historian’s job is not to make any critical examination or *report* it but simply to *repeat* it in his historical account (adding place and date).

Considering the scope and results of this rule, it might be called the principle of echolalia. The historian’s assessments are echoes of unanimous authoritative sayings. The historian tries to act as a mere servant, *ancilla scientiarum*, but he gets into serious trouble every time his masters disagree or there is a reversal of opinion.

A very different attitude is that of a historian who forms his own opinion as to what has and what has not been refuted, studying in detail the past situation at the frontier of science. The critical historian is in principle prepared to affirm that although this or that theory (or hypothesis) was unanimously *considered* refuted, it was not *in fact* refuted. The new, highly favorable external state of history of science permits a number of historians and scientists to delve into subjects deeply enough to take a responsible stand *within* the scientific debates of the past.

It is an important feature of the new historiography that the historian of science is considered to be just as free in his assessment of the truth-value and importance of any scientist’s utterance as the historian of politics is in relation to the utterances of politicians. Of course the historian is interested mainly in how the actors saw their situation, but he feels free to pass judgment, to declare them to have been completely deceived, deluded, in the dark. He applies the well-established methodology of textual criticism mercilessly and cynically to utterances of even the most

honored geniuses in science. Recently, the great physicists, who were active as recently as the 1920s, have been asked to “tell their own story.” Needless to say, their memories do not furnish any exact, detailed, or coherent account of “what really happened,” and the historians try to construct a survey or picture that is of a higher historical quality than that of any of the actors.

Applied to questions of refutation, the new attitude implies that if the historian can document ten scientists’ opinions (within a certain time interval) concerning the status of a given theory, his job will be, on the one hand, historically to understand and explain the utterances and, on the other hand, to offer his opinion as to the truth-value, tenability, etc., of the utterances in the light of later and contemporary development and within the framework of a definite, or several definite, philosophies of science.

The historian who has studied recently at various centers of philosophy of science knows that there are deep differences of attitude and doctrine and that any attempt to make a coherent synthesis cannot but fail to do justice to any of them and can only result in a loose, valueless form of eclecticism detrimental to both history and science.

Therefore, explicitness as to his own idiosyncracies is one of the scientific author’s greatest merits. But where it is lacking, the diligent student of the products of research will generally be able to see where the author “belongs.”

Thus, if scientist *A* has declared *T* refuted, one modern historian, *B*, may find that *T* was not refuted (in the sense intended by *A*) but merely weakened, or perhaps even strengthened, or that the test did not affect *T*. Or, more likely, *B* may accept the verdict of *A*, insofar as it refers (of course) to *A*’s own concept of refutation, but reflect that it is a different concept from his own, according to which the event referred to by *A* may bear no relation (other than irrelevance) to *T*’s refutation. But due to the radical plurality of contemporary differences in philosophy of science, another historian, *C*, accepting at least one assumption or rule or postulate that *B* does not hold, may interpret *A*’s text differently and therefore arrive at a different reconstruction of *A*’s concept (intention) or, if not that, at different conclusions concerning both the correctness of *A*’s claim (“refuted!”) and the relation of past events to what *C* calls “refutation.”

In short, the contemporary historian of science no longer feels constrained to adopt the terminology and conceptual framework of the scientists he studies, or even all of those adopted by his own contemporaries, in regard to assumptions, rules, or postulates.

It is the historian's job to elucidate the way scientists conceived their situation, introducing us to *their* conceptual framework and, if possible, to their *praxis*,⁶ but he can only do this on the basis of his own assessment of the situation, his own impression of who were the actors and what were the forces operating upon them—scientific, economic, and political. Ernest Gellner's surmise concerning societies as a whole also holds for the "subcultures" comprising scientific communities:

[T]he general characteristics of societies, their culture and their language, which enable their members to conceptualize aims and beliefs about environments, and which consequently are presupposed by special explanations, are not perhaps correctly represented by the beliefs of those members themselves. (Gellner 1968: 431)

Do we understand the printed matter and correspondence of scientists of the seventeenth century better or more poorly than they did themselves? It is tempting to answer, On the whole, more poorly. But the formidable collections now printed or available in archives make it possible to interpret each sentence of each letter in the light of the collected letters and printings. Many misinterpretations by seventeenth-century scientists are next to impossible to succumb to today. The intense prejudices of earlier times, due to jealousy and other strong emotions, are gone or weakened.

Collections of pictures and old instruments make it possible to repeat experiments under better-controlled conditions. Chemists did not work with analytically pure chemicals but with grossly impure materials. Today we often know exactly from which minerals and by what process they obtained their strange "salts" and "spirits." We are able to reproduce the impurities, and we understand better what they did and why they often got such queer results.

Yet there are, at any time, so many ideas "in the air" that are not articulated—but nevertheless influence the formulation and interpretation of words—that we must concede our ignorance or the crudeness of our guesses. And in any case, translation—at least in the ordinary sense of "translation," which means a rendering of expressions in one contempo-

rary language into expressions in another language belonging roughly to the same family of languages—is out of the question. If, for example, in the correspondence on Spinoza's experiments with what he called "nitrum" we translate the word into either the Old English word "nitre," or " NaNO_3 " or " KNO_3 " or "a mixture of NaNO_3 and KNO_3 ," or by a long phrase "the salt obtained by . . .," we get no such translation, but only a script that has certain isomorphies with the original.

The interpretation of a text from the seventeenth century will of course undergo considerable changes with time and will also vary greatly among historians with different preconceptions, interests, and philosophies. The same, only more pronounced, variation will characterize our *understanding*, more generally, of research at any given time in the past. This in turn influences our understanding of what we are ourselves doing, and therefore also of our text—which again influences our interpretation of historical documents (the hermeneutical circle).⁷

The tremendously complex genesis of our "knowledge of acids" is not a genesis of knowledge of a *definite* sort of thing, process, or substance. But we may, in terms of our present-day chemistry, plus the not inconsiderable mass of historical materials, trace a development of notions, conceptions, or even concepts that shows certain internal relations such that it is natural to say that they are all notions of acid. The idea that there is an accumulation of knowledge of acids, as defined today, through several hundreds of years, is untenable. We may, however, assert that there is an accumulation of knowledge of acid_1 , acid_2 , . . . , acid_n , where these are different notions in the past, and a stagnation in the accumulation, or even decrease, of knowledge relative to acid_{n+1} , acid_{n+2} , . . . , which are notions with no relation to research today. Decreases are possible because the term *knowledge* refers to relatively stable convictions within fairly uniform communities, not to verified hypotheses or theories. It would take an unusual amount of pessimism to believe that there has not been a *definitive* accumulation ("not-to-be-lost knowledge") concerning acids in some interpretations of the old term *acid*. But in principle, the model of growth, progress, or accumulation is such that there is no end to, and also an accumulating probability of, changes of notions and practice that result in incomparability.⁸ The model envisages revolutions, perhaps relatively often moderately deep and pervasive, though rarely extreme. But an extreme revolution breaks the previous accumulative period. (If the model

is subordinated under a certain model of social development, conclusions may be different: if it is envisaged that social conditions will ultimately be completely standardized and uniform, one definite kind of conceptual framework will be adopted and never change anymore. There will be a final revolution and unending accumulation afterward. Scientific revolutions presuppose social change.)

Refutation Seen in Historical Perspective

The following concluding remarks go no further than stating what seems clear from recent historical studies.

All that observations have furnished, however numerous and diversified, have been *instances* of disconfirmation, or *instances* of confirmation (corroboration) or support. To each instance there have normally been attached specific initial conditions or, more generally, relevant observational reports because properly trained researchers (according to the standards within a certain community at a certain epoch) are simply assumed to make reasonable evaluations of this sort. But the weight and relevance of the implicit premises for the conclusions of the scientist are on a par with premises explicitly mentioned by him.

In the light of this, I prefer in what follows to speak of “instances of disconfirmation of a theory” or “disconfirmatory instances” rather than of “disconfirmation of a theory.” Among other things, this way of speaking makes it more difficult to identify disconfirmation with falsification or refutation. One can hardly speak of there being *instances* of falsification or refutation of a theory. The “instance” of falsification makes it a false theory, and the “instance” of refutation refutes it. There is no place for, let us say, three falsifications (or refutations) and five nonfalsifications (or non-refutations) among the results of a test. But there may well be three disconfirmatory and five confirmatory instances. The “evidence” may be, in part, negative, in part positive. According to Paul Feyerabend (1969), we can dispense with confirmatory (positive) instances in science. *We can*, but why should we? Feyerabend claims that by doing so, we get rid of the paradox of confirmation in science because it refers only to positive instances. But in any case, the paradox does not concern methodology because the assessment of confirmatory instances is not (and need not be) of a kind suggested by a calculus of propositions or functions.

For example, let us examine the expression $(x) (Ax \supset Bx)$, for all x , if x has the property A , then x also has the property B . If this expression is forced on us as an *adequate* symbolic expression of a hypothesis (which it clearly is not), and if certain other dubious applications of logical calculi to nonformal languages are accepted, we will *deduce* that the expressions $Ax_1 \& Bx_1$ and $\sim Ax_2 \& \sim Bx_2$ refer to equally weighty positive instances. There is nothing in formal logic to prevent us from taking them equally seriously as confirmations of $(x) (Ax \supset Bx)$. But what is the relevance of this exercise in formal logic here?

What is more important is to test whether a sentence of the form $Ax \& Bx$ has the same relation to those of the form “if Ax then Bx ” as sentences of the form $\sim Ax \& \sim Bx$. (A test would soon furnish negative instances if the assumption can be said to be at all testable.)

Let us take an instance from research activity at the level of Gay-Lussac. From the general hypothesis that two liters of hydrogen and one liter of oxygen combine chemically to form two (not three) liters of water (as gas), we predict that the two liters of hydrogen in container C_1 will combine with one liter of oxygen in container C_2 to fill another container C_3 with two liters of water (as gas, if temperature and pressure are held constant). Suppose now that we get a confirmatory instance, as did Joseph-Louis Gay-Lussac in similar tests. Suppose further that we can limit the probable experimental error to within the range of ± 0.001 liters, or one cubic centimeter. Now why is this a *formidable* positive instance? Because previous to our hypothesis we had no grounds for supposing that the result should *not* have been, for example, three liters of water gas. Measured relative to the set of possible experimental results, the one obtained is highly special: the prediction rules out (*prohibits*) a large number of results of the operation. It would be *methodologically* nonsensical to combine two liters of water and one liter of milk and say that their combination as three liters of rather thin milk is an equally weighty positive instance (corresponding to $\sim Ax \& \sim Bx$). (If the universe consisted of only about a dozen things, however, the cases of $\sim Ax \& \sim Bx$ might be interesting.)

Our conclusion supports that of Feyerabend but dispenses with any need to deny that the presence of positive instances should not sometimes be taken as a decisive argument for continuing work with, or for adopting, a definite hypothesis (competing with other hypotheses). John Dalton fur-

nished some negative instances, but by sloppy handling of the gases. Contemporaries (unhappily) sided with Dalton, the luminary, against the relatively obscure Gay-Lussac.

Even at the methodologically uninteresting level of Baconian hypotheses like “all ravens are black,” the use of negative *and* positive evidence in any assessment of credibility is clear. Suppose *A* wishes to test the hypothesis, whereas *B* wishes to work with the hypothesis “some ravens are not black,” and they hire an ornithologist to observe as great a number of ravens as possible. Suppose he reports only black ones. The result is significant for *both A* and *B*, not only for *B*. If it is significant for the affirmation of *A*’s and *B*’s hypotheses, how could it not be significant for the negations of each of them?

My conclusion concerning the whole discussion on refutation is not “Theories are never falsified or refuted,” but rather “Theories that have long, dramatic histories may be said at any given time to have a certain status in relation to efforts of verification, refutation, confirmation, etc.” Viewed in the wide perspective of the historian of science, the changes of status are on the whole smaller than they appear to the practicing scientist. His judgments are not *sub specie aeternitatis*, but partly of local research strategy. What, to the personally involved scientist, seems to be a perfect instance of an *experimentum crucis* is to the historian but one interesting test in a potentially long series. The result, if negative, may completely undermine the status of the theory within the scientific community for even as long a period as a generation or two, but a revival is not forever out of the question. The scientist often speaks as if what was *decisive* when changing a research strategy in a given situation was a clear, impersonal proof or disproof, verification or falsification, in a strict cognitive sense. A modern historian may justifiably apply a more “voluntarist” or “personalist” terminology, perhaps one of which the scientist as well as the logician of science would vehemently disapprove.

The historian cannot distinguish consistently between (for instance) “*said* unanimously within the community of scientists to be disproved (refuted, shown to be false, etc.)” and “disproved (refuted, shown to be false, etc.),” at least not without some arbitrariness. Nevertheless the distinction is one he cannot avoid. It requires of the historian that he be explicit in *his* choice of criteria of disproof, refutation, and of other expressions of the status of a theory.
